TOTAL COST TO DECOMMISSION WITH 17.11% CONTINGENCY:	**$1,602,660**	**thousands of 2017 dollars**	
TOTAL NRC LICENSE TERMINATION COST IS 47.37% OR:	**$759,122**	**thousands of 2017 dollars**	
SPENT FUEL MANAGEMENT COST IS 48.18% OR:	**$772,214**	**thousands of 2017 dollars**	
NON-NUCLEAR DEMOLITION COST IS 4.45% OR:	**$71,324**	**thousands of 2017 dollars**	
TOTAL LOW-LEVEL RADIOACTIVE WASTE VOLUME BURIED (EXCLUDING GTCC):	**205,970**	**cubic feet**	
TOTAL GREATER THAN CLASS C RADWASTE VOLUME GENERATED:	**1,547**	**cubic feet**	
TOTAL SCRAP METAL REMOVED:	**22,696**	**tons**	
TOTAL CRAFT LABOR REQUIREMENTS:	**934,006**	**man-hours**	

End Notes:
n/a - indicates that this activity not charged as decommissioning expense
a - indicates that this activity performed by decommissioning staff
0 - indicates that this value is less than 0.5 but is non-zero
A cell containing " - " indicates a zero value

PERIOD 1a - Shutdown through Transition																					
Period 1a Direct Decommissioning Activities																					
1a.1.1	SAFSTOR site characterization survey	-	-	-	-	-	-	380	114	494	494	-	-	-	-	-	-	-	-	-	-
1a.1.2	Prepare preliminary decommissioning cost	-	-	-	-	-	-	153	23	175	175	-	-	-	-	-	-	-	-	-	1,300
1a.1.3	Notification of Cessation of Operations									a											
1a.1.4	Remove fuel & source material									n/a											
1a.1.5	Notification of Permanent Defueling									a											
1a.1.6	Deactivate plant systems & process waste									a											
1a.1.7	Prepare and submit PSDAR	-	-	-	-	-	-	235	35	270	270	-	-	-	-	-	-	-	-	-	2,000
1a.1.8	Review plant dwgs & specs.	-	-	-	-	-	-	153	23	175	175	-	-	-	-	-	-	-	-	-	1,300
1a.1.9	Perform detailed rad survey									a											
1a.1.10	Estimate by-product inventory	-	-	-	-	-	-	117	18	135	135	-	-	-	-	-	-	-	-	-	1,000
1a.1.11	End product description	-	-	-	-	-	-	117	18	135	135	-	-	-	-	-	-	-	-	-	1,000
1a.1.12	Detailed by-product inventory	-	-	-	-	-	-	176	26	202	202	-	-	-	-	-	-	-	-	-	1,500
1a.1.13	Define major work sequence	-	-	-	-	-	-	117	18	135	135	-	-	-	-	-	-	-	-	-	1,000
1a.1.14	Perform SER and EA	-	-	-	-	-	-	364	55	418	418	-	-	-	-	-	-	-	-	-	3,100
1a.1.15	Prepare/submit Defueled Technical Specifications	-	-	-	-	-	-	880	132	1,012	1,012	-	-	-	-	-	-	-	-	-	7,500
1a.1.16	Perform Site-Specific Cost Study	-	-	-	-	-	-	587	88	675	675	-	-	-	-	-	-	-	-	-	5,000
1a.1.17	Prepare/submit Irradiated Fuel Management Plan	-	-	-	-	-	-	117	18	135	135	-	-	-	-	-	-	-	-	-	1,000
Activity Specifications																					
1a.1.18.1	Prepare plant and facilities for SAFSTOR	-	-	-	-	-	-	578	87	664	664	-	-	-	-	-	-	-	-	-	4,920
1a.1.18.2	Plant systems	-	-	-	-	-	-	489	73	562	562	-	-	-	-	-	-	-	-	-	4,167
1a.1.18.3	Plant structures and buildings	-	-	-	-	-	-	366	55	421	421	-	-	-	-	-	-	-	-	-	3,120
1a.1.18.4	Waste management	-	-	-	-	-	-	235	35	270	270	-	-	-	-	-	-	-	-	-	2,000
1a.1.18.5	Facility and site dormancy	-	-	-	-	-	-	235	35	270	270	-	-	-	-	-	-	-	-	-	2,000
1a.1.18	Total	-	-	-	-	-	-	1,902	285	2,188	2,188	-	-	-	-	-	-	-	-	-	16,207
Detailed Work Procedures																					
1a.1.19.1	Plant systems	-	-	-	-	-	-	139	21	160	160	-	-	-	-	-	-	-	-	-	1,183
1a.1.19.2	Facility closeout & dormancy	-	-	-	-	-	-	141	21	162	162	-	-	-	-	-	-	-	-	-	1,200
1a.1.19	Total	-	-	-	-	-	-	280	42	322	322	-	-	-	-	-	-	-	-	-	2,383
1a.1.20	Procure vacuum drying system	-	-	-	-	-	-	12	2	13	13	-	-	-	-	-	-	-	-	-	100
1a.1.21	Drain/de-energize non-cont. systems									a											
1a.1.22	Drain & dry NSSS									a											
1a.1.23	Drain/de-energize contaminated systems									a											
1a.1.24	Decon/secure contaminated systems									a											
1a.1	Subtotal Period 1a Activity Costs	-	-	-	-	-	-	5,590	896	6,486	6,486	-	-	-	-	-	-	-	-	-	44,390
Period 1a Collateral Costs																					
1a.3.1	Spent Fuel Capital and Transfer	-	-	-	-	-	-	1,221	183	1,404	-	1,404	-	-	-	-	-	-	-	-	-
1a.3.2	Retention and Severance	-	-	-	-	-	-	9,892	1,484	11,376	11,376	-	-	-	-	-	-	-	-	-	-

Scenarios 3 and 4
(thousands of 2017 dollars)

Activity Description	Decon Costs	Removal Costs	Packaging Costs	Transport Costs	LLRW Disposal Costs	Other Costs	Total Costs	Burial Volume Class A (cubic feet)	Craft Manhours	Oversight and Contractor Manhours
Decommissioning Contractor										
Planning (characterization, specs and procedures)	-	-	-	-	-	241	241	-	-	1,072
Decontamination (activated disposition)	30	2	6	14	208	-	260	834	365	-
License Termination (radiological surveys)	-	-	-	-	-	1,262	1,262	-	10,268	-
Subtotal	**30**	**2**	**6**	**14**	**208**	**1,503**	**1,763**	**834**	**10,633**	**1,072**
Supporting Costs										
NRC and NRC Contractor Fees and Costs	-	-	-	-	-	364	364	-	-	776
Insurance	-	-	-	-	-	110	110	-	-	-
Property taxes	-	-	-	-	-	244	244	-	-	-
Plant energy budget	-	-	-	-	-	-	-	-	-	-
Fixed Overhead	-	-	-	-	-	82	82	-	-	-
Railroad Track Maintenance	-	-	-	-	-	38	38	-	-	-
Security Staff Cost	-	-	-	-	-	308	308	-	-	4,999
Oversight Staff	-	-	-	-	-	260	260	-	-	3,792
Subtotal	**-**	**-**	**-**	**-**	**-**	**1,407**	**1,407**	**-**	**-**	**9,568**
Total (w/o contingency)	**30**	**2**	**6**	**14**	**208**	**2,909**	**3,170**	**834**	**10,633**	**10,640**
Total (w/25% contingency)							**3,962**			

The application of contingency (25%) is consistent with the evaluation criteria referenced by the NRC in NUREG-1757 ("Consolidated Decommissioning Guidance, Financial Assurance, Recordkeeping, and Timeliness," U.S. NRC's Office of Nuclear Material Safety and Safeguards, NUREG-1757, Vol. 3, Rev. 1, February 2012)

DECOMMISSIONING COST ANALYSIS

for the

PRAIRIE ISLAND NUCLEAR GENERATING PLANT

prepared for

Xcel Energy

prepared by

TLG Services, Inc.
Bridgewater, Connecticut

October 2017

APPROVALS

Project Manager	**Francis W. Seymore**	**Date** 10/17/17
Project Engineer	**Jeffrey M. Martin**	**Date** 10/17/17
Technical Manager	**William A. Cloutier, Jr.**	**Date** 10/17/2017

TABLE OF CONTENTS

SECTION **PAGE**

EXECUTIVE SUMMARY ..... **viii**

1. INTRODUCTION **1-1**
1.1 Objectives of Study 1-1
1.2 Site Description 1-2
1.3 Regulatory Guidance 1-3
1.3.1 High-Level Radioactive Waste Management 1-5
1.3.2 Low-Level Radioactive Waste Disposal 1-9
1.3.3 Radiological Criteria for License Termination 1-10

2. DECOMMISSIONING ALTERNATIVES **2-1**
2.1 DECON 2-3
2.1.1 Period 0 (Pre-shutdown) and Period 1 - Preparations 2-3
2.1.2 Period 2 - Decommissioning Operations 2-5
2.1.3 Period 3 - Site Restoration 2-9
2.1.4 ISFSI Operations and Decommissioning 2-10
2.2 SAFSTOR 2-11
2.2.1 Period 0 (Pre-shutdown) and Period 1 - Preparations 2-11
2.2.2 Period 2 - Dormancy 2-12
2.2.3 Periods 3 and 4 - Delayed Decommissioning 2-13
2.2.4 Period 5 - Site Restoration 2-14

3. COST ESTIMATES **3-1**
3.1 Basis of Estimates 3-1
3.2 Methodology 3-1
3.3 Impact of Decommissioning Multiple Reactor Units 3-3
3.4 Financial Components of the Cost Model 3-4
3.4.1 Contingency 3-4
3.4.2 Financial Risk 3-7
3.5 Site-Specific Considerations 3-8
3.5.1 Spent Fuel Management 3-8
3.5.2 Reactor Vessel and Internal Components 3-13
3.5.3 Primary System Components 3-14
3.5.4 Main Turbine and Condenser 3-15
3.5.5 Transportation Methods 3-15
3.5.6 Low-Level Radioactive Waste Disposal 3-17
3.5.7 Site Conditions Following Decommissioning 3-18

TABLE OF CONTENTS
(continued)

SECTION **PAGE**

3.6 Assumptions 3-18
3.6.1 Estimating Basis 3-18
3.6.2 Labor Costs 3-19
3.6.3 Design Conditions 3-20
3.6.4 General 3-21
3.7 Cost Estimate Summary 3-25

4. SCHEDULE ESTIMATE 4-1
4.1 Schedule Estimate Assumptions 4-1
4.2 Project Schedule 4-2

5. RADIOACTIVE WASTES 5-1

6. RESULTS 6-1

7. REFERENCES 7-1

EXECUTIVE SUMMARY

This report presents estimates of the cost to decommission the Prairie Island Nuclear Generating Plant (Prairie Island) for the identified decommissioning scenarios following a cessation of plant operations and the operation and eventual decommissioning of the on-site Independent Spent Fuel Storage Installation (ISFSI). The estimates are designed to provide Xcel Energy with the information to assess its current decommissioning liability, as it relates to Prairie Island.

The analysis relies upon site-specific, technical information from an evaluation prepared in 2014,[1] updated to reflect current assumptions pertaining to the disposition of the nuclear plant and relevant industry experience in undertaking such projects. The costs are based on several key assumptions in areas of regulation, component characterization, high-level radioactive waste management, low-level radioactive waste disposal, performance uncertainties (contingency) and site restoration requirements.

The analysis is not a detailed engineering evaluation, but an estimate prepared in advance of the detailed engineering required to carry out the decommissioning of the nuclear units. It may also not reflect the actual plan to decommission Prairie Island; the plan may differ from the assumptions made in this analysis based on facts that exist at the time of decommissioning.

The primary goal of the decommissioning is the removal and disposal of the contaminated systems and structures so that the plant's operating licenses can be terminated. The analysis recognizes that spent fuel will be stored at the site in the plant's storage pool and/or in an Independent Spent Fuel Storage Installation (ISFSI) until such time that it can be transferred to a Department of Energy (DOE) facility. Consequently, the estimates also include those costs to manage and subsequently decommission these storage facilities.

The current cost estimates assume that Prairie Island Unit 1 ceases operations in 2033, and 2034 for Unit 2. The cost estimates assume that the shutdown dates of the nuclear units are scheduled and pre-planned (i.e., there is no delay in transitioning the plant and workforce from operations or in obtaining regulatory relief from operating requirements, etc.). This estimate includes additional resources to support the engineering, planning, and licensing efforts for the station; this is done to support a decommissioning schedule similar to the prior estimate. The estimates include the continued operation of the auxiliary building as an interim wet fuel storage facility for

1 "Decommissioning Cost Analysis for the Prairie Island Nuclear Generating Plant," Document No. X01-1617-007, Rev. 0, TLG Services, Inc., September 2014

approximately five years after operations cease. The spent fuel will remain in the ISFSI until the DOE is able to complete the transfer of the fuel to a federal facility (e.g., a monitored retrievable storage facility).[2] The estimates also include the dismantling of non-essential structures and limited restoration of the site.

The costs to decommission Prairie Island, for the scenarios evaluated, are tabulated at the end of this section. Costs are reported in 2017 dollars and include monies anticipated to be spent for radiological remediation and operating license termination, spent fuel management, and site restoration activities.

A complete discussion of the assumptions relied upon in this analysis is provided in Section 3, along with schedules of annual expenditures for each scenario. A sequence of significant project activities is provided in Section 4 with a timeline for each scenario. Detailed cost reports used to generate the summary tables contained within this document are provided in Appendices C through J.

Alternatives and Regulations

The ultimate objective of the decommissioning process is to reduce the inventory of contaminated and activated material so that the licenses can be terminated. The Nuclear Regulatory Commission (NRC or Commission) provided initial decommissioning requirements in its rule adopted on June 27, 1988.[3] In this rule, the NRC set forth technical and financial criteria for decommissioning licensed nuclear power facilities. The regulations addressed planning needs, timing, funding methods, and environmental review requirements for decommissioning. The rule also defined three decommissioning alternatives as being acceptable to the NRC: DECON, SAFSTOR, and ENTOMB.

> DECON is defined as "the alternative in which the equipment, structures, and portions of a facility and site containing radioactive contaminants are removed or decontaminated to a level that permits the property to be released for unrestricted use shortly after cessation of operations."[4]

---

2 Projected expenditures for spent fuel management identified in the cost analysis do not consider any compensation for damages with regard to the delays incurred by Xcel Energy in the timely removal of spent fuel by the DOE.

3 U.S. Code of Federal Regulations, Title 10, Parts 30, 40, 50, 51, 70 and 72, "General Requirements for Decommissioning Nuclear Facilities," Nuclear Regulatory Commission, 53 Fed. Reg. 24018, June 27, 1988

4 Ibid. Page FR24022, Column 3

SAFSTOR is defined as "the alternative in which the nuclear facility is placed and maintained in a condition that allows the nuclear facility to be safely stored and subsequently decontaminated (deferred decontamination) to levels that permit release for unrestricted use."[5] Decommissioning is to be completed within 60 years, although longer time periods will be considered when necessary to protect public health and safety.

ENTOMB is defined as "the alternative in which radioactive contaminants are encased in a structurally long-lived material, such as concrete; the entombed structure is appropriately maintained and continued surveillance is carried out until the radioactivity decays to a level permitting unrestricted release of the property."[6] As with the SAFSTOR alternative, decommissioning is currently required to be completed within 60 years, although longer time periods will also be considered when necessary to protect public health and safety.

The 60-year restriction has limited the practicality for the ENTOMB alternative at commercial reactors that generate significant amounts of long-lived radioactive material. In 1997, the Commission directed its staff to re-evaluate this alternative and identify the technical requirements and regulatory actions that would be necessary for entombment to become a viable option. The resulting evaluation provided several recommendations, however, rulemaking has been deferred based upon several factors (e.g., no licensee has committed to pursuing the entombment option, the unresolved issues associated with the disposition of greater-than-Class C material (GTCC), and the NRC's current priorities) at least until after the additional research studies are complete. The Commission concurred with the staff's recommendation. In a draft regulatory basis document published in March 2017 in support of rulemaking that would amend NRC regulations concerning nuclear plant decommissioning, the NRC staff proposes removing any discussion of the ENTOMB option from existing guidance documents since the method is not deemed practically feasible.

In 1996, the NRC published revisions to its general requirements for decommissioning nuclear power plants to clarify ambiguities and codify procedures and terminology as a means of enhancing efficiency and uniformity in the decommissioning process.[7] The amendments allow for greater public participation and better define the transition

7 U.S. Code of Federal Regulations, Title 10, Parts 2, 50 and 51, "Decommissioning of Nuclear Power Reactors," Nuclear Regulatory Commission, 61 Fed. Reg. 39278, July 29, 1996

process from operations to decommissioning. Regulatory Guide 1.184 Revision 1, issued in October 2013, further described the methods and procedures that are acceptable to the NRC staff for implementing the requirements of the 1996 revised rule that relate to the initial activities and the major phases of the decommissioning process. The costs and schedules presented in this analysis follow the general guidance and sequence in the amended regulations. The format and content of the estimates is also consistent with the recommendations of Regulatory Guide 1.202, issued February 2005.[8]

In 2011, the NRC published amended regulations to improve decommissioning planning and thereby reduce the likelihood that any current operating facility will become a legacy site.[9] The amended regulations require licensees to conduct their operations to minimize the introduction of residual radioactivity into the site, which includes the site's subsurface soil and groundwater. Licensees also may be required to perform site surveys to determine whether residual radioactivity is present in subsurface areas and to keep records of these surveys with records important for decommissioning. The amended regulations require licensees to report additional details in their decommissioning cost estimate as well as requiring additional financial reporting and assurances. These additional details are included in this analysis, including the ISFSI decommissioning estimate (Appendix J).

Decommissioning Scenarios

The following scenarios were evaluated and are intended to bound the liability associated with the removal of spent fuel from the site. The current operating licenses expires in 2033 and 2034 for Units 1 and 2, respectively. The scenarios consist of five DECON scenarios, with differing spent fuel management assumptions, but essentially no changes to the decommissioning costs and timing of the power block. There are also two SAFSTOR scenarios (Scenarios 6 and 7) each corresponding to the first two DECON scenario spent fuel management assumptions. The spent fuel in the plant's spent fuel storage pool is transferred to the ISFSI within the first five years. The equipment, structures, and portions of the plant containing radioactive contaminants are removed or decontaminated to a level that permits the facility to be released for unrestricted use. Non-essential structures are then demolished. Spent fuel storage operations continue at the ISFSI until the transfer of the fuel to the DOE is completed (2064 in Scenarios 1 & 6, 2077 in Scenarios 2, 5 & 7, 2117 in Scenario 3, and 2217 in Scenario 4).

7	n/a	2053	2077	SAFSTOR with 60 Year DFS

+ Dry Fuel Storage

For Scenarios 1 and 6, although they only provide a total fuel storage period of 32 years following plant shutdown, some of the Prairie Island casks have been in storage since 1995. Xcel Energy directed TLG Services to not include the cost of transferring the spent fuel in dry storage to new canisters for those casks that exceed 50 years. The assumption to not transfer spent fuel at 50 years total storage duration for these two scenarios was premised on the likelihood that the life of the canisters could be successfully managed for the additional years.

For Scenarios 2 and 7, although they provide a total fuel storage period of 60 years following plant shutdown, Xcel Energy directed TLG Services to not include the cost of transferring the spent fuel in dry storage to new canisters at 50 years after plant shutdown.

In Scenarios 3, 4 and 5, the DSCs are assumed to be replaced after fifty years of use. Since the auxiliary building spent fuel storage pool and fuel handling facilities are removed by the year 2040, a dry fuel transfer facility is assumed to be constructed on site to perform the transfers from the old to the new DSCs. For Scenarios 3 and 5, only one such transfer is needed over the time frame assumed (some fuel canisters in Scenario 5 will not require recasking). For Scenario 4, the spent fuel will be transferred three times following initial placement in the ISFSI.

Methodology

The methodology used to develop the estimates follows the basic approach originally presented in the cost estimating guidelines[10] developed by the Atomic Industrial Forum (now Nuclear Energy Institute). This reference describes a unit cost factor method for estimating decommissioning activity costs. The unit cost factors used in this analysis incorporate site-specific costs and the latest available information about worker productivity in decommissioning.

An activity duration critical path is used to determine the total decommissioning program schedule. This is required for calculating the carrying costs, which include program management, administration, field engineering, equipment rental, quality assurance, and security. This systematic approach for assembling decommissioning estimates ensures a high degree of confidence in the reliability of the resulting costs.

The estimates also reflect lessons learned from previously completed decommissioning projects, including TLG's involvement in the Shippingport Station decommissioning, completed in 1989, and the decommissioning of the Cintichem reactor, hot cells and associated facilities, completed in 1997. In addition, the planning and engineering for the Pathfinder, Shoreham, Rancho Seco, Trojan, Yankee Rowe, Big Rock Point, Maine Yankee, Humboldt Bay-3, Oyster Creek, Connecticut Yankee, Crystal River, Vermont Yankee and Fort Calhoun nuclear units have provided additional insight into the process, the regulatory aspects, and the technical challenges of decommissioning commercial nuclear units.

Contingency

Consistent with cost estimating practice, contingencies are applied to the decontamination and dismantling costs developed as "specific provision for unforeseeable elements of cost within the defined project scope, particularly important where previous experience relating estimates and actual costs has shown that unforeseeable events which will increase costs are likely to occur."[11] The cost elements in the estimates are based on ideal conditions; therefore, the types of unforeseeable events that are almost certain to occur in decommissioning, based on industry experience, are addressed through a percentage contingency applied on a line-item basis. This contingency factor is a nearly universal element in all large-scale construction and demolition projects. It should be noted that contingency, as used in

10 T.S. LaGuardia et al., "Guidelines for Producing Commercial Nuclear Power Plant Decommissioning Cost Estimates," AIF/NESP-036, May 1986

11 Project and Cost Engineers' Handbook, Second Edition, American Association of Cost Engineers, Marcel Dekker, Inc., New York, New York, p. 239

this analysis, does not account for price escalation and inflation in the cost of decommissioning over the remaining operating life of the station, or duration of the decommissioning program and dry fuel storage period.

Contingency funds are expected to be fully expended throughout the program. As such, inclusion of contingency is necessary to provide assurance that sufficient funding will be available to accomplish the intended tasks.

Low-Level Radioactive Waste Disposal

The contaminated and neutron-activated material generated in the decontamination and dismantling of a commercial nuclear reactor is classified as low-level (radioactive) waste, although not all of the material is suitable for "shallow-land" disposal. With the passage of the "Low-Level Radioactive Waste Policy Act" in 1980,[12] and its Amendments of 1985,[13] the states became ultimately responsible for the disposition of low-level radioactive waste generated within their own borders. It was expected that groups of states would combine together to jointly deal with their radioactive wastes; these organizations are referred to as waste disposal compacts.

With the exception of Texas, no new compact facilities have been successfully sited, licensed, and constructed. The Texas Compact disposal facility is now operational and waste is being accepted from generators within the Compact by the operator, Waste Control Specialists (WCS). The facility is also able to accept limited quantities of non-Compact waste.

Disposition of the various waste streams produced by the decommissioning process considered all options and services currently available to Xcel Energy. The majority of the low-level radioactive waste designated for direct disposal (Class A[14]) can be sent to Energy*Solutions*' facility in Clive, Utah. Therefore, disposal costs for Class A waste were based upon representative rates. This facility is not licensed to receive the higher activity portion (Classes B and C) of the decommissioning waste stream.

The Texas facility is licensed to receive the higher activity waste forms (Classes B and C). As such, for this analysis, disposal costs for the Class B and C waste were based upon the preliminary and indicative information on the cost for such from WCS.

12 "Low-Level Radioactive Waste Policy Act," Public Law 96-573, 1980

13 "Low-Level Radioactive Waste Policy Amendments Act of 1985," Public Law 99-240, 1986

14 Waste is classified in accordance with U.S. Code of Federal Regulations, Title 10, Part 61.55

The dismantling of the components residing closest to the reactor core generates radioactive waste considered unsuitable for shallow-land disposal (i.e., low-level radioactive waste with concentrations of radionuclides that exceed the limits established by the NRC for Class C radioactive waste (GTCC)). The Low-Level Radioactive Waste Policy Amendments Act of 1985 assigned the federal government the responsibility for the disposal of this material. The Act also stated that the beneficiaries of the activities resulting in the generation of such radioactive waste bear all reasonable costs of disposing of such waste. However, to date, the federal government has not identified a cost for disposing of GTCC or a schedule for acceptance.

For purposes of this analysis, the GTCC radioactive waste is assumed to be packaged and disposed of in a similar manner as high-level waste and at a cost equivalent to that envisioned for the spent fuel. The GTCC is packaged in the same canisters used for spent fuel and either stored on site or shipped directly to a DOE facility as it is generated (depending upon the timing of the decommissioning and whether the spent fuel has been removed from the site prior to the start of decommissioning).

A significant portion of the waste material generated during decommissioning may only be potentially contaminated by radioactive materials. This waste can be analyzed on site or shipped off site to licensed facilities for further analysis, for processing and/or for conditioning/recovery. Reduction in the volume of low-level radioactive waste requiring disposal in a licensed low-level radioactive waste disposal facility can be accomplished through a variety of methods, including analyses and surveys or decontamination to isolate the portion of waste that does not require disposal as radioactive waste, compaction, incineration or metal melt. The estimates reflect the savings from waste recovery/volume reduction.

<u>High-Level Radioactive Waste Management</u>

Congress passed the "Nuclear Waste Policy Act"[15] (NWPA) in 1982, assigning the federal government's long-standing responsibility for disposal of the spent nuclear fuel created by the commercial nuclear generating plants to the DOE. The NWPA provided that DOE would enter into contracts with utilities in which DOE would promise to take the utilities' spent fuel and high-level radioactive waste and utilities would pay the cost of the disposition services for that material. NWPA, along with the individual contracts with the utilities, specified that the DOE was to begin accepting spent fuel by January 31, 1998.

15 "Nuclear Waste Policy Act of 1982 and Amendments," DOE's Office of Civilian Radioactive Management, 1982

Since the original legislation, the DOE has announced several delays in the program schedule. By January 1998, the DOE had failed to accept any spent fuel or high-level waste, as required by the NWPA and utility contracts. Delays continue and, as a result, generators have initiated legal action against the DOE in an attempt to obtain compensation for DOE's partial breach of contract. To date no spent fuel has been accepted from commercial generating sites for disposal.

In 2010 the Obama Administration appointed a Blue Ribbon Commission on America's Nuclear Future (Blue Ribbon Commission) to make recommendations for a new plan for nuclear waste disposal. The Blue Ribbon Commission's charter includes a requirement that it consider "[o]ptions for safe storage of used nuclear fuel while final disposition pathways are selected and deployed."[16]

On January 26, 2012, the Blue Ribbon Commission issued its "Report to the Secretary of Energy" containing a number of recommendations on nuclear waste disposal. Two of the recommendations that may impact decommissioning planning are:

- "[T]he United States [should] establish a program that leads to the timely development of one or more consolidated storage facilities"[17]
- "[T]he United States should undertake an integrated nuclear waste management program that leads to the timely development of one or more permanent deep geological facilities for the safe disposal of spent fuel and high-level nuclear waste."[18]

In January 2013, the DOE issued the "Strategy for the Management and Disposal of Used Nuclear Fuel and High-Level Radioactive Waste," in response to the recommendations made by the Blue Ribbon Commission and as "a framework for moving toward a sustainable program to deploy an integrated system capable of transporting, storing, and disposing of used nuclear fuel..."[19] This document states:

"With the appropriate authorizations from Congress, the Obama Administration planned to implement a program over the next 10 years that would have:

---

16 Charter of the Blue Ribbon Commission on America's Nuclear Future, "Objectives and Scope of Activities," 2010

17 "Blue Ribbon Commission on America's Nuclear Future, Report to the Secretary of Energy,", p. 32, January 2012

18 Ibid., p.27

19 "Strategy for the Management and Disposal of Used Nuclear Fuel and High-Level Radioactive Waste," U.S. DOE, January 11, 2013

- Sites, designs and licenses, constructs and begins operations of a pilot interim storage facility by 2021 with an initial focus on accepting used nuclear fuel from shut-down reactor sites;
- Advances toward the siting and licensing of a larger interim storage facility to be available by 2025 that will have sufficient capacity to provide flexibility in the waste management system and allows for acceptance of enough used nuclear fuel to reduce expected government liabilities; and
- Makes demonstrable progress on the siting and characterization of repository sites to facilitate the availability of a geologic repository by 2048."[20]

The NRC's review of DOE's license application to construct a geologic repository at Yucca Mountain was suspended in 2011 when the Obama Administration slashed the budget for completing that work. However, the US Court of Appeals for the District of Columbia Circuit issued a writ of mandamus (in August 2013) [21] ordering NRC to comply with federal law and restart its review of DOE's Yucca Mountain repository license application to the extent of previously appropriated funding for the review. That review is now complete with the publication of the five-volume safety evaluation report. A supplement to DOE's environmental impact statement and an adjudicatory hearing on the contentions filed by interested parties must be completed before a licensing decision can be made.

The state of Minnesota directed the Public Utilities Commission, "when considering approval of a plan for the accrual of funds for the decommissioning of nuclear facilities" …to "include an evaluation of the costs, if any, arising from storage of used nuclear fuel that may be incurred by the state of Minnesota, and any tribal community, county, city, or township where used nuclear fuel is located following the cessation of operations at a nuclear plant."[22]

The state of Minnesota statute also prescribed the parameters to be used in evaluating spent fuel management costs. "To assist the commission in making the determination … the filing shall provide cost estimates, including ratepayer impacts, assuming used

---

20 Ibid., p.2

21 United States Court of Appeals for the District Of Columbia Circuit, In Re: Aiken County, et al, August 2013

22 Minnesota Statute 216B.1614, "Nuclear Power Plant Decommissioning and Storage of Used Nuclear Fuel"

nuclear fuel will be stored in the state for 60 years, 100 years, and 200 years following the cessation of operation of the nuclear plant." [23]

Xcel Energy's current spent fuel management plan for the Prairie Island spent fuel is based in general upon:

1) Fuel transferred from the pool to the ISFSI within 5 years of shutdown;
2) Exchange of Prairie Island and Monticello spent fuel acceptance rights to best manage the overall cost of spent fuel storage for both plants;
3) Fuel will be shipped in the existing NUHOMS DSCs (Scenarios 1, 2, 6, and 7); the canisters and NUHOMS are periodically replaced in Scenarios 3, 4 and 5. Canisters that are unloaded in the spent fuel transfer operation will be surveyed for neutron activation.
4) As an allowance, some of these canisters and NUHOMS modules from the first off-load operation are assumed to be mildly neutron activated and therefore must be disposed of as radioactive waste.

The NRC requires that licensees establish a program to manage and provide funding for the caretaking of all irradiated fuel at the reactor site until title of the fuel is transferred to the Secretary of Energy, pursuant to 10 CFR Part 50.54(bb).[24] This requirement is prepared for through inclusion of certain cost elements in the decommissioning estimates, for example, associated with the isolation and continued operation of the spent fuel pool and the ISFSI.

The spent fuel pool is expected to contain freshly discharged assemblies (from the most recent refueling cycles) as well as the final reactor cores at shutdown. The assemblies are packaged into dry shielded canisters (DSCs) over the first five years after shutdown for transfer to the ISFSI for interim storage. It is assumed that this period provides the necessary cooling for the final cores to meet the transport and/or storage requirements for decay heat.

An ISFSI, operated under a Part 72 Site Specific License (in accordance with 10 CFR 72[25]), has been constructed to support continued plant operations. The facility is assumed to be expanded to support decommissioning. This will allow decommissioning activities to proceed within the auxiliary building.

---

23 Ibid.

24 U.S. Code of Federal Regulations, Title 10, Part 50, "Domestic Licensing of Production and Utilization Facilities," Subpart 54 (bb), "Conditions of Licenses"

25 U.S. Code of Federal Regulations, Title 10, Part 72.40

DOE has breached its obligations to remove fuel from reactor sites, and has also failed to provide the plant owners with information about how it will ultimately perform. DOE officials have stated that DOE does not have an obligation to accept already-canistered fuel without an amendment to DOE's contracts with plant licensees to remove the fuel (the "Standard Contract"), but DOE has not explained what any such amendment would involve. Consequently, Xcel Energy has no information or expectations on how DOE will remove fuel from the site in the future. In the absence of information about how DOE will perform, and for purposes of this analysis only, it is assumed that DOE will accept already-canistered fuel. If this assumption is incorrect, it is assumed that DOE will have liability for costs incurred to transfer the fuel to DOE-supplied containers.

Xcel Energy's position is that the DOE has a contractual obligation to accept Prairie Island's fuel earlier than the projections set out above consistent with its contract commitments. No assumption made in this study should be interpreted to be inconsistent with this claim. However, including the cost of storing spent fuel in this study is appropriate to ensure the availability of sufficient decommissioning funds at the end of the station's life if the DOE has not met its obligation. The cost for the interim storage of spent fuel has been calculated and is separately presented as "Spent Fuel Management" expenditures in this report.

Site Restoration

The efficient removal of the contaminated materials at the site may result in damage to many of the site structures. Blasting, coring, drilling, and the other decontamination activities can substantially damage power block structures, potentially weakening the footings and structural supports. It is unreasonable to anticipate that these structures would be repaired and preserved after the radiological contamination is removed. The cost to dismantle site structures with a work force already mobilized is more efficient and less costly than if the process were deferred. Experience at shutdown generating stations has shown that plant facilities quickly degrade without maintenance, adding additional expense and creating potential hazards to the public and the demolition work force.

This estimate assumes that some site features will remain following the decommissioning project. These include the existing electrical switchyard, which is assumed to remain functional in support of the regional electrical distribution system. The existing shoreline will also be left intact.

Consequently, non-essential site structures addressed by this analysis are completely removed (including foundations) as required by Minnesota statute [26].

[26] Minnesota Administrative Rule part 7035.0400 "General Requirements"

The site is then graded and stabilized. The cost for the site restoration of non-essential and/or non-contaminated structures has been calculated and is separately presented as "Site Restoration" expenditures in this report.

Summary

The costs to decommission the Prairie Island station were evaluated for several decommissioning scenarios, based upon the DECON and SAFSTOR decommissioning alternatives. Regardless of the timing of the decommissioning activities, the estimates to decommission Prairie Island assume the removal of all contaminated and activated plant components and structural materials such that Xcel Energy may then have unrestricted use of the site with no further requirements for any operating license. In most of the scenarios, spent fuel remains on site following the decommissioning and site restoration of the power block structures. The spent fuel remains in storage at the site until such time that the transfer to a DOE facility can be completed. Once the transfer is complete, the storage facilities are also decommissioned.

The alternatives evaluated in this analysis are described in Section 2. The assumptions are presented in Section 3, along with schedules of annual expenditures. The major cost contributors are identified in Section 6, with detailed activity costs, waste volumes, and associated manpower requirements delineated in Appendices C through J. The major cost components are also identified in the cost summary provided at the end of this section.

The estimates presented in this document reflects the total cost to decontaminate the nuclear units, manage the spent fuel until the DOE is able to complete the transfer to a federal facility, dismantle the plant and restore the site for alternative use.

The cost elements in the estimates for the five DECON and two SAFSTOR alternatives are assigned to one of three subcategories: NRC License Termination (radiological remediation), Spent Fuel Management, and Site Restoration. The subcategory “NRC License Termination” is used to accumulate costs that are consistent with “decommissioning” as defined by the NRC in its financial assurance regulations (i.e., 10 CFR §50.75). The cost reported for this subcategory is generally sufficient to terminate the unit’s operating license, recognizing that there may be some additional cost impact from spent fuel management. The License Termination cost subcategory also includes costs to decommission the ISFSI (as required by 10 CFR §72.30). Section 3.4.1 provides the basis for the ISFSI decommissioning cost.

The “Spent Fuel Management” subcategory contains costs associated with the containerization and transfer of spent fuel from the wet storage pool to a DOE

transport cask or to the ISFSI for interim storage, as well as the transfer of the spent fuel in storage at the ISFSI to the DOE. Costs are included for the operation of the storage pool and the management of the ISFSI until such time that the transfer is complete. It does not include any spent fuel management expenses incurred prior to the cessation of plant operations, nor does it include any costs related to the final disposal of the spent fuel.

"Site Restoration" is used to capture costs associated with the dismantling and demolition of buildings and facilities demonstrated to be free from contamination. This includes structures never exposed to radioactive materials, as well as those facilities that have been decontaminated to appropriate levels. Structures are completely removed (including foundations) and backfilled to conform to local surface elevation.

It should be noted that the costs assigned to these subcategories are allocations. Delegation of cost elements is for the purposes of comparison (e.g., with NRC financial guidelines) or to permit specific financial treatment (e.g., Asset Retirement Obligation determinations). In reality, there can be considerable interaction between the activities in the three subcategories. For example, Xcel Energy may decide to remove non-contaminated structures early in the project to improve access to highly contaminated facilities or plant components. In these instances, the non-contaminated removal costs could be reassigned from Site Restoration to an NRC License Termination support activity. However, in general, the allocations represent a reasonable accounting of those costs that can be expected to be incurred for the specific subcomponents of the total estimated program cost, if executed as described.

As noted within this document, the estimates were developed and costs are presented in 2017 dollars. As such, the estimates do not reflect the escalation of costs (due to inflationary and market forces) over the remaining operating life of the plant or during the decommissioning period.

SCENARIO 1: DECON WITH 32 YEARS DFS
DECOMMISSIONING COST ELEMENTS
(thousands of 2017 dollars)

Cost Element	Unit 1	Unit 2	Total
Decontamination	11,899	18,712	30,611
Removal	103,458	132,270	235,727
Packaging	37,613	37,981	75,594
Transportation	8,386	8,908	17,294
Waste Disposal	65,232	68,234	133,465
Off-site Waste Processing	13,548	16,016	29,565
Program Management [1]	224,195	206,995	431,191
Site Security	116,834	106,450	223,284
Spent Fuel Pool Isolation	13,445	8,963	22,409
Spent Fuel Management	120,903	118,936	239,839
Insurance and Regulatory Fees	17,840	15,425	33,266
Energy	9,248	8,349	17,597
Characterization and Licensing Surveys	17,216	19,157	36,374
Property Taxes	54,492	51,594	106,086
Miscellaneous	7,188	7,147	14,335
Railroad Track Maintenance	2,598	2,517	5,116
Retention and Severance	28,423	28,423	56,845
Security Modifications	5,000	5,000	10,000
Prairie Island Indian Community Payments	40,000	38,750	78,750
Total [3]	897,520	899,828	1,797,347

Cost Element	Unit 1	Unit 2	Total
NRC License Termination	571,980	561,832	1,133,812
Spent Fuel Management	274,479	271,262	545,741
Site Restoration	51,061	66,733	117,795
Total [3]	897,520	899,828	1,797,347

[1] Includes engineering costs

[2] Includes costs for the dry storage system components, spent fuel loading and transfer, spent fuel pool O&M and EP fees, but excludes program management costs (staffing), security and other related costs

[3] Columns may not add due to rounding

SCENARIO 2: DECON WITH 60 YEAR DFS
DECOMMISSIONING COST ELEMENTS
(thousands of 2017 dollars)

Cost Element	Unit 1	Unit 2	Total
Decontamination	11,899	18,711	30,610
Removal	103,561	132,372	235,933

1. INTRODUCTION

This report presents estimates of the cost to decommission the Prairie Island Nuclear Generating Plant (Prairie Island) and the operation and eventual decommissioning of the on-site Independent Spent Fuel Storage Installation (ISFSI) for the selected decommissioning scenarios following the scheduled cessation of plant operations. The estimates are designed to provide Xcel Energy with the information to assess its current decommissioning liability, as it relates to Prairie Island.

The analysis relies upon site-specific, technical information from an earlier evaluation prepared in 2014,[1]* updated to reflect current assumptions pertaining to the disposition of the nuclear plant and relevant industry experience in undertaking such projects. The costs are based on several key assumptions in areas of regulation, component characterization, high-level radioactive waste management, low-level radioactive waste disposal, performance uncertainties (contingency) and site restoration requirements.

The analysis is not a detailed engineering evaluation, but an estimate prepared in advance of the detailed engineering required to carry out the decommissioning of the nuclear units. It may also not reflect the actual plan to decommission Prairie Island; the plan may differ from the assumptions made in this analysis based on facts that exist at the time of decommissioning.

The 2014 plant inventory was reviewed for this analysis. It serves as the basis for the decontamination and dismantling requirements, cost, and the decommissioning waste streams. The review confirmed that there were no substantive changes to the configuration of the plant or site facilities that would impact decommissioning over the last three years. Removal of new FLEX facilities was included.

1.1 OBJECTIVES OF STUDY

The objectives of this study are to prepare comprehensive estimates of the cost to decommission Prairie Island, to provide a sequence or schedule for the associated activities, and to develop waste stream projections from the decontamination and dismantling activities.

The operating licenses were originally issued for the plant in August 1973 and October 1974 for Units 1 and 2, respectively, and were valid for a period of 40

* Annotated references for citations in Sections 1-6 are provided in Section 7

years. In April 2008, Nuclear Management Company (as agent for Xcel Energy), submitted an application for renewed licenses (i.e., 20 year extensions). The application was approved by the NRC in June 2011. Therefore, for the purposes of this study, final shutdown dates (license expiration) for Unit 1 and Unit 2 are August 9, 2033 and October 29, 2034, respectively, assuming a 60-year operating life (the current operating licenses' expiration dates).

1.2 SITE DESCRIPTION

Prairie Island is located on the west bank of the Mississippi River, approximately 26 miles southeast of the Twin City Metropolitan Area and within the city limits of Red Wing. The site is in Goodhue County, Minnesota.

The Nuclear Steam Supply System (NSSS) consists of a pressurized water reactor and a two-loop reactor coolant system. The system is comprised of the reactor vessel and two closed reactor coolant loops connected in parallel to the reactor vessel, each containing a reactor coolant pump and a steam generator. An electrically heated pressurizer is connected to one of the loops.

The system is housed within the reactor containment vessel, a free-standing cylindrical steel shell with a hemispherical dome and ellipsoidal bottom designed to withstand the internal pressure accompanying a loss-of-coolant accident. The reactor containment vessel is surrounded by a cylindrical shield building constructed of reinforced concrete, which serves as a radiation shielding for normal operations and for the loss-of-coolant condition.

Heat produced in the reactor is converted to electrical energy by the plant's power conversion system. A turbine-generator converts the thermal energy of steam produced in the steam generators into mechanical shaft power and then into electrical energy. The turbine-generator consists of one high-pressure, double-flow and two low-pressure, double-flow elements driving a direct-coupled generator at 1800 rpm. The turbines are operated in a closed feedwater cycle in which the steam is condensed and returned to the steam generators by the feedwater system.

Heat rejected in the main condensers is removed by the circulating water system, which provides the heat sink for the removal of the waste heat in the power plant's thermal cycle. The majority of the heat is removed through dilution with river water in the discharge canal. Forced draft cooling towers provided supplemental heat removal.

1.3 REGULATORY GUIDANCE

The Nuclear Regulatory Commission (NRC or Commission) provided initial decommissioning requirements in its rule "General Requirements for Decommissioning Nuclear Facilities," issued in June 1988.[2] This rule set forth financial criteria for decommissioning licensed nuclear power facilities. The regulation addressed decommissioning planning needs, timing, funding methods, and environmental review requirements. The intent of the rule was to ensure that decommissioning would be accomplished in a safe and timely manner and that adequate funds would be available for this purpose. Subsequent to the rule, the NRC issued Regulatory Guide 1.159, "Assuring the Availability of Funds for Decommissioning Nuclear Reactors,[3]" which provided additional guidance to the licensees of nuclear facilities on the financial methods acceptable to the NRC staff for complying with the requirements of the rule. The regulatory guide addressed the funding requirements and provided guidance on the content and form of the financial assurance mechanisms indicated in the rule.

The rule defined three decommissioning alternatives as being acceptable to the NRC: DECON, SAFSTOR, and ENTOMB. The DECON alternative assumes that any contaminated or activated portion of the plant's systems, structures, and facilities are removed or decontaminated to levels that permit the site to be released for unrestricted use shortly after the cessation of plant operations while the SAFSTOR and ENTOMB alternatives defer the process.

The rule also placed limits on the time allowed to complete the decommissioning process. For the SAFSTOR alternative, the process is restricted in overall duration to 60 years, unless it can be shown that a longer duration is necessary to protect public health and safety. The guidelines for ENTOMB are similar, providing the NRC with both sufficient leverage and flexibility to ensure that these deferred options are only used in situations where it is reasonable and consistent with the definition of decommissioning. At the conclusion of a 50 to 60-year dormancy period (or longer for ENTOMB if the NRC approves such a case), the site would still require significant remediation to meet the unrestricted release limits for license termination.

The ENTOMB alternative has not been viewed as a viable option for power reactors due to the significant time required to isolate the long-lived radionuclides for decay to permissible levels. However, with rulemaking permitting the controlled release of a site,[4] the NRC did re-evaluate the alternative. The resulting feasibility study, based upon an assessment by Pacific Northwest National Laboratory, concluded that the method did have conditional merit for some, if not most reactors. The staff also found that

additional rulemaking would be needed before this option could be treated as a generic alternative.

The NRC had considered rulemaking to alter the 60-year time for completing decommissioning and to clarify the use of engineered barriers for reactor entombments.[5] However, the NRC's staff has recommended that rulemaking be deferred, based upon several factors, e.g., no licensee has committed to pursuing the entombment option, the unresolved issues associated with the disposition of greater-than-Class C material (GTCC), and the NRC's current priorities, at least until after the additional research studies are complete. The Commission concurred with the staff's recommendation. In a draft regulatory basis document published in March 2017 in support of rulemaking that would amend NRC regulations concerning nuclear plant decommissioning, the NRC staff proposes removing any discussion of the ENTOMB option from existing guidance documents since the method is not deemed practically feasible.

In 1996, the NRC published revisions to the general requirements for decommissioning nuclear power plants.[6] When the regulations were originally adopted in 1988, it was assumed that the majority of licensees would decommission at the end of the facility's operating licensed life. Since that time, several licensees permanently and prematurely ceased operations. Exemptions from certain operating requirements were required once the reactor was defueled to facilitate the decommissioning. Each case was handled individually, without clearly defined generic requirements. The NRC amended the decommissioning regulations in 1996 to clarify ambiguities and codify procedures and terminology as a means of enhancing efficiency and uniformity in the decommissioning process. The new amendments allow for greater public participation and better define the transition process from operations to decommissioning.

Under the revised regulations, licensees will submit written certification to the NRC within 30 days after permanent shutdown. Certification will also be required once the fuel is permanently removed from the reactor vessels. Submittal of these notices will entitle the licensee to a fee reduction and eliminate the obligation to follow certain requirements needed only during operation of the reactor. Within two years of submitting notice of permanent cessation of operations, the licensee is required to submit a Post-Shutdown Decommissioning Activities Report (PSDAR) to the NRC. The PSDAR describes the planned decommissioning activities, the associated sequence and schedule, and an estimate of expected costs. Prior to completing decommissioning, the licensee is required to submit applications to the NRC to terminate the license, which will include a License Termination Plan (LTP).

In 2011, the NRC published amended regulations to improve decommissioning planning and thereby reduce the likelihood that any current operating facility will become a legacy site.[7] The amended regulations require licensees to conduct their operations to minimize the introduction of residual radioactivity into the site, which includes the site's subsurface soil and groundwater. Licensees also may be required to perform site surveys to determine whether residual radioactivity is present in subsurface areas and to keep records of these surveys with records important for decommissioning. The amended regulations require licensees to report additional details in their decommissioning cost estimate as well as requiring additional financial reporting and assurances. These additional details, including an ISFSI decommissioning estimate, are included in this analysis.

1.3.1 High-Level Radioactive Waste Management

Congress passed the "Nuclear Waste Policy Act"[8] (NWPA) in 1982, assigning the federal government's long-standing responsibility for disposal of the spent nuclear fuel created by the commercial nuclear generating plants to the DOE. The NWPA provided that DOE would enter into contracts with utilities in which DOE would promise to take the utilities' spent fuel and high-level radioactive waste and utilities would pay the cost of the disposition services for that material. NWPA, along with the individual contracts with the utilities, specified that the DOE was to begin accepting spent fuel by January 31, 1998.

Since the original legislation, the DOE has announced several delays in the program schedule. By January 1998, the DOE had failed to accept any spent fuel or high level waste, as required by the NWPA and utility contracts. Delays continue and, as a result, generators have initiated legal action against the DOE in an attempt to obtain compensation for DOE's partial breach of contract. To date no spent fuel has been accepted from commercial generating sites for disposal.

In 2010, the Obama Administration appointed a Blue Ribbon Commission on America's Nuclear Future (Blue Ribbon Commission) to make recommendations for a new plan for nuclear waste disposal. The Blue Ribbon Commission's charter includes a requirement that it consider "[o]ptions for safe storage of used nuclear fuel while final disposition pathways are selected and deployed."[9]

On January 26, 2012, the Blue Ribbon Commission issued its "Report to the Secretary of Energy" containing a number of recommendations on

nuclear waste disposal. Two of the recommendations that may impact decommissioning planning are:

- "[T]he United States [should] establish a program that leads to the timely development of one or more consolidated storage facilities"[10]
- "[T]he United States should undertake an integrated nuclear waste management program that leads to the timely development of one or more permanent deep geological facilities for the safe disposal of spent fuel and high-level nuclear waste."

In January 2013, the DOE issued the "Strategy for the Management and Disposal of Used Nuclear Fuel and High-Level Radioactive Waste," in response to the recommendations made by the Blue Ribbon Commission and as "a framework for moving toward a sustainable program to deploy an integrated system capable of transporting, storing, and disposing of used nuclear fuel..."[11] This document states:

"With the appropriate authorizations from Congress, the Obama Administration planned to implement a program over the next 10 years that would have:

- Sites, designs and licenses, constructs and begins operations of a pilot interim storage facility by 2021 with an initial focus on accepting used nuclear fuel from shut-down reactor sites;
- Advances toward the siting and licensing of a larger interim storage facility to be available by 2025 that will have sufficient capacity to provide flexibility in the waste management system and allows for acceptance of enough used nuclear fuel to reduce expected government liabilities; and
- Makes demonstrable progress on the siting and characterization of repository sites to facilitate the availability of a geologic repository by 2048."

The NRC's review of DOE's license application to construct a geologic repository at Yucca Mountain was suspended in 2011 when the Obama Administration slashed the budget for completing that work. However, the US Court of Appeals for the District of Columbia Circuit issued a writ of mandamus (in August 2013) [12] ordering NRC to comply with federal law and restart its review of DOE's Yucca Mountain repository license application to the extent of previously appropriated funding for the review. That review is now complete with the publication of the five-

volume safety evaluation report. A supplement to DOE's environmental impact statement and an adjudicatory hearing on the contentions filed by interested parties must be completed before a licensing decision can be made.

The state of Minnesota directed the Public Utilities Commission, "when considering approval of a plan for the accrual of funds for the decommissioning of nuclear facilities" …to "include an evaluation of the costs, if any, arising from storage of used nuclear fuel that may be incurred by the state of Minnesota, and any tribal community, county, city, or township where used nuclear fuel is located following the cessation of operations at a nuclear plant."[13]

The state of Minnesota statute also prescribed the parameters to be used in evaluating spent fuel management costs. "To assist the commission in making the determination … the filing shall provide cost estimates, including ratepayer impacts, assuming used nuclear fuel will be stored in the state for 60 years, 100 years, and 200 years following the cessation of operation of the nuclear plant."

Xcel Energy's current spent fuel management plan for the Prairie Island spent fuel is based in general upon:

1) Fuel transferred from the pool to the ISFSI within 5 years of shutdown;
2) Exchange of Prairie Island and Monticello spent fuel acceptance rights to best manage the overall cost of spent fuel storage for both plants;
3) Fuel assemblies currently stored in the ISFSI use TN-40 casks. It's assumed that, starting with final shutdown, and for future recasking, that a NUHOMS system (with a capacity of 37 fuel assemblies, and similar in dimensions to the existing Monticello NUHOMS design) will be used instead of the TN-40 casks. Fuel will be shipped in the existing TN-40s or NUHOMS DSCs (Scenarios 1, 2, 6, and 7); the TN-40s are replaced with NUHOMS in Scenarios 3, 4 and 5. Canisters that are unloaded in the spent fuel transfer operation will be surveyed for neutron activation.
4) This estimate does not include any costs for replacing cask head bolts, gaskets, or installation of spacers within the existing TN-40 cask prior to shipment to DOE.

5) As an allowance, some of these canisters and NUHOMS modules from the first off-load operation are assumed to be mildly neutron activated and therefore must be disposed of as radioactive waste.

The NRC requires that licensees establish a program to manage and provide funding for the caretaking of all irradiated fuel at the reactor site until title of the fuel is transferred to the Secretary of Energy, pursuant to 10 CFR Part 50.54(bb).[14] This requirement is prepared for through inclusion of certain cost elements in the decommissioning estimates, for example, associated with the isolation and continued operation of the spent fuel pool and the ISFSI.

The spent fuel pool is expected to contain freshly discharged assemblies (from the most recent refueling cycles) as well as the final reactor cores at shutdown. In the DECON and SAFSTOR scenarios, the assemblies are packaged into dry shielded canisters (DSCs) over the first five years after shutdown for transfer to the ISFSI for interim storage. It is assumed that this period provides the necessary cooling for the final cores to meet the transport and/or storage requirements for decay heat.

An ISFSI, operated under a Part 72 Site Specific License (in accordance with 10 CFR 72[15]), has been constructed to support continued plant operations. The facility is assumed to be expanded to support decommissioning. This will allow decommissioning activities to proceed within the auxiliary building.

DOE has breached its obligations to remove fuel from reactor sites, and has also failed to provide the plant owners with information about how it will ultimately perform. DOE officials have stated that DOE does not have an obligation to accept already-canistered fuel without an amendment to DOE's contracts with plant licensees to remove the fuel (the "Standard Contract"), but DOE has not explained what any such amendment would involve. Consequently, Xcel Energy has no information or expectations on how DOE will remove fuel from the site in the future. In the absence of information about how DOE will perform, and for purposes of this analysis only, it is assumed that DOE will accept already-canistered fuel. If this assumption is incorrect, it is assumed that DOE will have liability for costs incurred to transfer the fuel to DOE-supplied containers.

Xcel Energy's position is that the DOE has a contractual obligation to accept Prairie Island's fuel earlier than the projections set out above, consistent with its contract commitments. No assumption made in this study should be interpreted to be inconsistent with this claim. However, including the cost of storing spent fuel in this study is appropriate to ensure the availability of sufficient decommissioning funds at the end of the station's life if the DOE has not met its obligation. The cost for the interim storage of spent fuel has been calculated and is separately presented as "Spent Fuel Management" expenditures in this report.

1.3.2 Low-Level Radioactive Waste Disposal

The contaminated and activated material generated in the decontamination and dismantling of a commercial nuclear reactor is classified as low-level (radioactive) waste, although not all of the material is suitable for "shallow-land" disposal. With the passage of the "Low-Level Radioactive Waste Policy Act" in 1980,[16] and its Amendments of 1985,[17] the states became ultimately responsible for the disposition of low-level radioactive waste generated within their own borders. It was expected that groups of states would combine together to jointly deal with their radioactive wastes; these organizations are referred to as waste disposal compacts.

With the exception of Texas, no new compact facilities have been successfully sited, licensed, and constructed. The Texas Compact disposal facility is now operational and waste is being accepted from generators within the Compact by the operator, Waste Control Specialists (WCS). The facility is also able to accept limited quantities of non-Compact waste.

Disposition of the various waste streams produced by the decommissioning process considered all options and services currently available to Xcel Energy. The majority of the low-level radioactive waste designated for direct disposal (Class A[18]) can be sent to Energy*Solutions*' facility in Clive, Utah. Therefore, disposal costs for Class A waste were based upon representative rates. This facility is not licensed to receive the higher activity portion (Classes B and C) of the decommissioning waste stream.

The Texas facility is licensed to receive the higher activity waste forms (Classes B and C). As such, for this analysis, disposal costs for the Class B and C waste were based upon the preliminary and indicative information on the cost for such from WCS.

The dismantling of the components residing closest to the reactor core generates radioactive waste considered unsuitable for shallow-land disposal (i.e., low-level radioactive waste with concentrations of radionuclides that exceed the limits established by the NRC for Class C radioactive waste (GTCC)). The Low-Level Radioactive Waste Policy Amendments Act of 1985 assigned the federal government the responsibility for the disposal of this material. The Act also stated that the beneficiaries of the activities resulting in the generation of such radioactive waste bear all reasonable costs of disposing of such waste. However, to date, the federal government has not identified a cost for disposing of GTCC or a schedule for acceptance.

For purposes of this analysis, the GTCC radioactive waste is assumed to be packaged and disposed of in a similar manner as high-level waste (i.e., in a geologic repository) and at a cost equivalent to that envisioned for the spent fuel. The GTCC is packaged in the same canisters used for spent fuel and either stored on site or shipped directly to a DOE facility as it is generated (depending upon the timing of the decommissioning and whether the spent fuel has been removed from the site prior to the start of decommissioning).

A significant portion of the metallic waste material generated during decommissioning may only be potentially contaminated by radioactive materials. This waste can be surveyed on site or shipped off site to licensed facilities for further analysis, for processing and/or for conditioning/recovery. Reduction in the volume of low-level radioactive waste requiring disposal in a licensed low-level radioactive waste disposal facility can be accomplished through a variety of methods, including analyses and surveys or decontamination to isolate the portion of waste that does not require disposal as radioactive waste, compaction, incineration or metal melt. The estimates reflect the savings from waste recovery/volume reduction.

1.3.3 Radiological Criteria for License Termination

In 1997, the NRC published Subpart E, "Radiological Criteria for License Termination,"[19] amending 10 CFR §20. This subpart provides radiological criteria for releasing a facility for unrestricted use. The regulation states that the site can be released for unrestricted use if radioactivity levels are such that the average member of a critical group would not receive a Total Effective Dose Equivalent (TEDE) in excess of 25 millirem per year, and provided that residual radioactivity has been reduced to levels that are As Low As Reasonably Achievable (ALARA).

The decommissioning estimates for Prairie Island assume that the site will be remediated to a residual level consistent with the NRC-prescribed level for radioactive material.

It should be noted that the NRC and the Environmental Protection Agency (EPA) differ on the amount of residual radioactivity considered acceptable in site remediation. The EPA has two limits that apply to radioactive materials. An EPA limit of 15 millirem per year is derived from criteria established by the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA or Superfund).[20] An additional and separate limit of 4 millirem per year, as defined in 40 CFR §141.66, is applied to drinking water.[21]

On October 9, 2002, the NRC signed an agreement with the EPA on the radiological decommissioning and decontamination of NRC-licensed sites. The Memorandum of Understanding (MOU)[22] provides that EPA will defer exercise of authority under CERCLA for the majority of facilities decommissioned under NRC authority. The MOU also includes provisions for NRC and EPA consultation for certain sites when, at the time of license termination, (1) groundwater contamination exceeds EPA-permitted levels; (2) NRC contemplates restricted release of the site; and/or (3) residual radioactive soil concentrations exceed levels defined in the MOU.

The MOU does not impose any new requirements on NRC licensees and should reduce the involvement of the EPA with NRC licensees who are decommissioning. Most sites are expected to meet the NRC criteria for unrestricted use, and the NRC believes that only a few sites will have groundwater or soil contamination in excess of the levels specified in the MOU that trigger consultation with the EPA. However, if there are other hazardous materials on the site, the EPA may be involved in the cleanup. As such, the possibility of dual regulation remains for certain licensees. The present study does not include any costs for this occurrence.

2. DECOMMISSIONING ALTERNATIVES

Detailed cost estimates were developed to decommission Prairie Island based upon the approved decommissioning alternatives: DECON and SAFSTOR. Although the alternatives differ with respect to technique, process, cost, and schedule, they attain the same result: the ultimate release of the site for unrestricted use.

The following scenarios were evaluated and are intended to bound the liability associated with the removal of spent fuel from the site. The current operating licenses expire in 2033 and 2034. The scenarios consist of five DECON scenarios, with differing spent fuel management assumptions, but essentially no changes to the decommissioning costs and timing of the power block. There are also two SAFSTOR scenarios (Scenarios 6 and 7) each corresponding to the first two DECON scenario spent fuel management assumptions. The spent fuel in the plant's spent fuel storage pool is transferred to the ISFSI within the first five years. The equipment, structures, and portions of the plant containing radioactive contaminants are removed or decontaminated to a level that permits the facility to be released for unrestricted use. Non-essential structures are then demolished. Spent fuel storage operations continue at the ISFSI until the transfer of the fuel to the DOE is completed (2064 in Scenarios 1 & 6, 2077 in Scenarios 2, 5 & 7, 2117 in Scenario 3, and 2217 in Scenario 4).

Scenario	1st Spent Fuel Canister Replacement	1st Spent Fuel Assembly Removed from Prairie Island	Last Spent Fuel Assembly Removed from Prairie Island	Scenario Identification
1	n/a	2027	2064	DECON with 32 Year DFS+
2	n/a	2053	2077	DECON with 60 Year DFS
3	2045	2093	2117	DECON with 100 Year DFS
4	2045	2193	2217	DECON with 200 Year DFS
5	2045	2053	2077	DECON with 60 Year DFS and recasking
6	n/a	2027	2064	SAFSTOR with 32 Year DFS
7	n/a	2053	2077	SAFSTOR with 60 Year DFS

+ Dry Fuel Storage

For Scenarios 1 and 6, although they only provide a total fuel storage period of 32 years following plant shutdown, some of the Prairie Island casks have been in storage since 1995. Xcel Energy directed TLG Services to not include the cost of transferring the spent fuel in dry storage to new canisters for those casks that exceed 50 years. The assumption to not transfer spent fuel at 50 years total storage duration for these two scenarios was premised on the likelihood that the life of the canisters could be successfully managed for the additional years.

For Scenarios 2 and 7, although they provide a total fuel storage period of 60 years following plant shutdown, Xcel Energy directed TLG Services to not include the cost of transferring the spent fuel in dry storage to new canisters at 50 years after plant shutdown.

In Scenarios 3, 4 and 5, the DSCs are assumed to be replaced after fifty years of use. Since the auxiliary building spent fuel storage pool and fuel handling facilities are removed by the year 2040, a dry fuel transfer facility is assumed to be constructed on site to perform the transfers from the old to the new DSCs. For Scenarios 3 and 5, only one such transfer is needed over the time frame assumed (some fuel canisters in Scenario 5 will not require recasking). For Scenario 4, the spent fuel will be transferred three times following initial placement in the ISFSI.

The following sections describe the basic activities associated with each alternative. Although detailed procedures for each activity identified are not provided, and the actual sequence of work may vary, the activity descriptions provide a basis not only for estimating but also for the expected scope of work (i.e., engineering and planning at the time of decommissioning).

The conceptual approach that the NRC has described in its regulations divides decommissioning into three phases. The initial phase commences with the effective date of permanent cessation of operations and involves the transition of both plant and licensee from reactor operations (i.e., power production) to facilitate de-activation and closure. During the first phase, notification is to be provided to the NRC certifying the permanent cessation of operations and the removal of fuel from the reactor vessels. The licensee would then be prohibited from reactor operation.

The second phase encompasses activities during the storage period or during major decommissioning activities, or a combination of the two. The third phase pertains to the activities involved in license termination. The decommissioning estimates developed for Prairie Island are also divided into phases or periods; however, demarcation of the phases is based upon major milestones within the project or significant changes in the projected expenditures.

2.1 DECON

The DECON alternative, as defined by the NRC, is "the alternative in which the equipment, structures, and portions of a facility and site containing radioactive contaminants are removed or decontaminated to a level that permits the property to be released for unrestricted use shortly after cessation of operations." This study does not address the cost to dispose of the spent fuel residing at the site; such costs are funded through a surcharge on electrical generation. However, the study does estimate the costs incurred with the interim on-site storage of the fuel pending shipment by the DOE to an off-site disposal facility. Those costs are separately presented as "Spent Fuel Management" expenditures in this report.

2.1.1 Period 1 - Preparations

In anticipation of the cessation of plant operations, detailed preparations are undertaken to provide a smooth transition from plant operations to site decommissioning. Through implementation of a staffing transition plan, the organization required to manage the intended decommissioning activities is assembled from available plant staff and outside resources. Preparations include the planning for permanent defueling of the reactor, revision of technical specifications applicable to the operating conditions and requirements, a characterization of the facility and major components, and the development of the PSDAR.

Engineering and Planning

The PSDAR, required prior to, or within two years of permanent cessation of operations, provides a description of the licensee's planned decommissioning activities, a timetable, a site-specific decommissioning cost estimate, and the associated financial requirements of the intended decommissioning program. Upon receipt of the PSDAR, the NRC will make the document available to the public for comment in a local meeting to be held in the vicinity of the reactor site. Ninety days following submittal and NRC receipt of the PSDAR, the licensee may begin to perform major decommissioning activities under a modified 10 CFR §50.59 procedure, (10 CFR §50.59 establishes the conditions under which licensees may make changes to the facility or procedures and conduct test or experiments, i.e., without prior NRC approval). Major activities are defined as any activity that results in permanent removal of major radioactive components, permanently modifies the structure of the containment, or results in dismantling components (for shipment)

containing GTCC, as defined by 10 CFR §61. Major components are further defined as comprising the reactor vessel and internals, large bore reactor coolant system piping, and other large components that are radioactive. The NRC includes the following additional criteria for use of the §50.59 process in decommissioning. The proposed activity must not:

- foreclose release of the site for possible unrestricted use,
- significantly increase decommissioning costs,
- cause any significant environmental impact not previously reviewed, or
- result in there no longer being reasonable assurance that adequate funds will be available for decommissioning

Existing operational technical specifications are reviewed and modified to reflect plant conditions and the safety concerns associated with permanent cessation of operations. The environmental impact associated with the planned decommissioning activities is also considered. Typically, a licensee will not be allowed to proceed if the consequences of a particular decommissioning activity are greater than that bounded by previously evaluated environmental assessments or impact statements. In this instance, the licensee would have to submit a license amendment for the specific activity and update the environmental report.

The decommissioning program outlined in the PSDAR will be designed to accomplish the required tasks within the ALARA guidelines (as defined in 10 CFR §20) for protection of personnel from exposure to radiation hazards. It will also address the continued protection of the health and safety of the public and the environment during the dismantling activity. Consequently, with the development of the PSDAR, activity specifications, cost-benefit and safety analyses, and work packages and procedures, would be assembled to support the proposed decontamination and dismantling activities.

Site Preparations

Following final plant shutdown, and in preparation for actual decommissioning activities, the following activities are initiated:

- Characterization of the site and surrounding environs. This includes radiation surveys of work areas, major components (including the

reactor vessel and its internals), internal piping, and primary shield cores.

- An ISFSI has been constructed to support continued plant operation and will need to be expanded following the cessation of operations to offload the spent fuel pool in support of the decommissioning program.
- Isolation of the spent fuel storage pool and fuel handling systems, such that decommissioning operations can commence on the balance of the plant. Decommissioning operations are scheduled around the fuel handling area to optimize the overall project schedule. It is assumed that the fuel pool remains operational for the transfer of fuel for approximately five years following the cessation of operations.
- Specification of transport and disposal requirements for activated materials and/or hazardous materials, including shielding and waste stabilization.
- Development of procedures for occupational exposure control, control and release of liquid and gaseous effluent, processing of radwaste (including dry-active waste, resins, filter media, metallic and non-metallic components generated in decommissioning), site security and emergency programs, and industrial safety.
- Perform chemical decontamination of the NSSS to reduce radiation levels in support of removal operations

2.1.2 Period 2 - Decommissioning Operations

This period includes the physical decommissioning activities associated with the removal and disposal of contaminated and activated components and structures, including the successful amendment of the 10 CFR §50 operating licenses (releasing the site, exclusive of the ISFSI). Significant decommissioning activities in this phase include:

- Construction of temporary facilities and/or modification of existing facilities to support dismantling activities. This may include a centralized processing area to facilitate equipment removal and component preparations for off-site disposal.
- Reconfiguration and modification of site structures and facilities as needed to support decommissioning operations. This may include the upgrading of roads (on- and off-site) to facilitate hauling and transport. Modifications may be required to the containment

structure to facilitate access of large/heavy equipment. Modifications may also be required to the refueling area of the building to support the segmentation of the reactor vessel internals and component extraction.

- Transfer of the spent fuel from the storage pool to the ISFSI pad for interim storage.
- Design and fabrication of temporary and permanent shielding to support removal and transportation activities, construction of contamination control envelopes, and the procurement of specialty tooling.
- Procurement (lease or purchase) of shipping canisters, cask liners, and industrial packages.
- Decontamination of components and piping systems as required to control (minimize) worker exposure.
- Removal of piping and components no longer essential to support decommissioning operations.
- Removal of control rod drive housings and the head service structure from reactor vessel head. Segment the vessel closure head.
- Removal and segmentation of the upper internals assemblies. Segmentation will maximize the loading of the shielded transport casks, (i.e., by weight and activity). The operations are conducted under water using remotely operated tooling and contamination controls.
- Disassembly and segmentation of the remaining reactor internals, including the core former and lower core support assembly. Some material is expected to exceed Class C disposal requirements. As such, the segments will be packaged in modified spent fuel storage canisters for geologic disposal.
- Segmentation of the reactor vessel. A shielded platform is installed for segmentation as cutting operations are performed in air using remotely operated equipment within a contamination control envelope. The water level is maintained just below the cut to minimize the working area dose rates. Segments are transferred in-air to containers that are stored under water, for example, in an isolated area of the refueling canal.
- Removal of the activated portions of the concrete biological shield and accessible contaminated concrete surfaces. If dictated by the steam generator and pressurizer removal scenarios, those portions of the

associated cubicles necessary for access and component extraction are removed.

- Removal of the steam generators and pressurizer for material recovery and controlled disposal. The generators will be moved to an on-site processing center, the steam domes are removed and the internal components segregated for off-site processing. The lower shell and tube bundle will be packaged for direct disposal. These components can serve as their own burial containers provided that all penetrations are properly sealed and the internal contaminants are stabilized. Steel shielding is added, as necessary, to those external areas of the steam generators to meet transportation limits and regulations.
- Expansion of the ISFSI and transfer of the spent fuel from the storage pool to the ISFSI pad for interim storage. Spent fuel storage operations continue throughout the active decommissioning period. Fuel transfer to DOE is expected to be completed by the end of the year 2064 (Scenario 1).

At least two years prior to the anticipated date of license termination, an LTP is required. Submitted as a supplement to the Final Safety Analysis Report (FSAR) or its equivalent, the plan must include: a site characterization, description of the remaining dismantling activities, plans for site remediation, procedures for the final radiation survey, designation of the end use of the site, an updated cost estimate to complete the decommissioning, and any associated environmental concerns. The NRC will notice the receipt of the plan, make the plan available for public comment, and schedule a local meeting. LTP approval will be subject to any conditions and limitations as deemed appropriate by the Commission. The licensee may then commence with the final remediation of site facilities and services, including:

- Removal of remaining plant systems and associated components as they become nonessential to the decommissioning program or worker health and safety (e.g., waste collection and treatment systems, electrical power and ventilation systems).
- Removal of the steel liners from the refueling canal, disposing of the activated and contaminated sections as radioactive waste. Removal of any activated/contaminated concrete.
- Surveys of the decontaminated areas of the containment structure.
- Removal of the contaminated equipment and material from the auxiliary building and any other contaminated facility. Use radiation

and contamination control techniques until radiation surveys indicate that the structures can be released for unrestricted access and conventional demolition. This activity may necessitate the dismantling and disposition of most of the systems and components (both clean and contaminated) located within these buildings. This activity will facilitate surface decontamination and subsequent verification surveys required prior to obtaining release for demolition.

- Removal of the remaining components, equipment, and plant services in support of the area release survey(s).
- Routing of material removed in the decontamination and dismantling to a central processing area. Material certified to be free of contamination is released for unrestricted disposition, e.g., as scrap, recycle, or general disposal. Contaminated material is characterized and segregated for additional off-site processing (disassembly, chemical cleaning, volume reduction, and waste treatment), and/or packaged for controlled disposal at a low-level radioactive waste disposal facility.

Incorporated into the LTP is the Final Survey Plan. This plan identifies the radiological surveys to be performed once the decontamination activities are completed and is developed using the guidance provided in the "Multi-Agency Radiation Survey and Site Investigation Manual (MARSSIM)."[23] This document incorporates the statistical approaches to survey design and data interpretation used by the EPA. It also identifies commercially available instrumentation and procedures for conducting radiological surveys. Use of this guidance ensures that the surveys are conducted in a manner that provides a high degree of confidence that applicable NRC criteria are satisfied. Once the survey is complete, the results are provided to the NRC in a format that can be verified. The NRC then reviews and evaluates the information, performs an independent confirmation of radiological site conditions, and makes a determination on the requested change to the operating licenses (that would release the property, exclusive of the ISFSI, for unrestricted use).

The NRC will amend the operating licenses to reduce the licensed area to the ISFSI area if it determines that site remediation has been performed in accordance with the LTP, and that the terminal radiation survey and associated documentation demonstrate that the property (exclusive of the ISFSI) is suitable for release.

2.1.3 Period 3 - Site Restoration

Following completion of decommissioning operations, site restoration activities will begin. Efficient removal of the contaminated materials and verification that residual radionuclide concentrations are below the NRC limits will result in substantial damage to many of the structures. Although performed in a controlled and safe manner, blasting, coring, drilling, scarification (surface removal), and the other decontamination activities will substantially degrade power block structures including the reactor and auxiliary buildings. Under certain circumstances, verifying that subsurface radionuclide concentrations meet NRC site release requirements will require removal of grade slabs and lower floors, potentially weakening footings and structural supports. This removal activity will be necessary for those facilities and plant areas where historical records, when available, indicate the potential for radionuclides having been present in the soil, where system failures have been recorded, or where it is required to confirm that subsurface process and drain lines were not breached over the operating life of the station.

Dismantling of site structures following decommissioning is clearly the most appropriate and cost-effective option. It is unreasonable to anticipate that these structures would be repaired and preserved after the radiological contamination is removed. The effort to dismantle site structures with a work force already mobilized on site is more efficient than if the process were deferred. Site facilities quickly degrade without maintenance, adding additional expense and creating potential hazards to the public as well as to future workers. Abandonment creates a breeding ground for vermin infestation as well as other biological hazards.

This cost study presumes that non-essential structures and site facilities are dismantled as a continuation of the decommissioning activity. Foundations and exterior walls are completely removed, including foundations and basemats as required by Minnesota regulations. [24] Site areas affected by the dismantling activities are restored and the plant area graded as required to prevent ponding, establish erosion control by the planting of native vegetation, and inhibit the refloating of subsurface materials.

Non-contaminated concrete rubble produced by demolition activities is processed to remove reinforcing steel and miscellaneous embedments. All non-contaminated materials are trucked to an off-site area for

disposal as construction debris. Subgrade voids are backfilled with clean construction fill, suitable under Minnesota regulations.

2.1.4 ISFSI Operations and Decommissioning

The ISFSI will continue to operate under a site-specific license as authorized by 10 CFR Part 72 following the amendment of the operating license to release the adjacent (power block) property. Assuming that Prairie Island spent fuel shipments begin in 2027, the process is not expected to be completed until 2064 (Scenario 1). Any delay in the transfer process, for example, due to a delay in the scheduled opening of the geologic repository, a slower acceptance rate, or a combination of both, can result in a longer on-site residence time for the fuel discharge from the reactor, as well as additional caretaking expenses. Scenarios 3 and 4 address extended delay periods. Scenarios 3, 4 and 5 also reflect an assumption that the spent fuel DSCs will need to be replaced every fifty years.

The assumed design for the ISFSI is based upon the use of the existing TN-40 casks from Transnuclear, plus the use of a multi-purpose dry shielded storage canister and a horizontal storage module for pad storage for those fuel assemblies packaged after plant shutdown.

At the conclusion of the spent fuel transfer process, the ISFSI will be decommissioned. The Commission will terminate the license if it determines that the remediation of the ISFSI has been performed in accordance with an ISFSI license termination plan and that the final radiation survey and associated documentation demonstrate that the facility is suitable for release. Once the requirements are satisfied, the NRC can terminate the license for the ISFSI.

For purposes of this cost analysis, it is assumed that once the TN-40s and DSCs containing the spent fuel assemblies have been removed, any required decontamination is performed on the storage overpacks (some minor neutron-induced activation is assumed), and the license for the facility terminated, the concrete overpacks can be dismantled using conventional techniques for the demolition of reinforced concrete. The concrete storage pad is then removed and the area regraded. This topic is discussed in greater detail in section 3.4.1.

2.2 SAFSTOR

The NRC defines SAFSTOR as "the alternative in which the nuclear facility is placed and maintained in a condition that allows the nuclear facility to be safely stored and subsequently decontaminated (deferred decontamination) to levels that permit release for unrestricted use." The facility is left intact (during the dormancy period), with structures maintained in a sound condition. Systems not required to operate in support of the spent fuel pool or site surveillance and security are drained, de-energized, and secured. Minimal cleaning/removal of loose contamination and/or fixation and sealing of remaining contamination are performed. Access to contaminated areas is secured to provide controlled access for inspection and maintenance.

The engineering and planning requirements are similar to those for the DECON alternative. Site preparations are also similar to those for the DECON alternative. However, with the exception of the required radiation surveys and site characterizations, the mobilization and preparation of site facilities is less extensive.

2.2.1 Period 1 - Preparations

Preparations for long-term storage include the planning for permanent defueling of the reactors, revision of technical specifications appropriate to the operating conditions and requirements, a characterization of the facility and major components, and the development of the PSDAR.

The process of placing the plant in safe-storage includes, but is not limited to, the following activities:

- Isolation of the spent fuel storage services and fuel handling systems located in the auxiliary building so that safe-storage operations may commence on the balance of the plant. This activity may be carried out by plant personnel in accordance with existing operating technical specifications. Activities are scheduled around the fuel handling systems to the greatest extent possible.
- Draining and de-energizing of the non-contaminated systems not required to support continued site operations or maintenance.
- Disposing of contaminated filter elements and resin beds not required for processing wastes from layup activities for future operations.
- Draining of the reactor vessels, with the internals left in place and the vessel heads secured.

- Draining and de-energizing non-essential, contaminated systems with decontamination as required for future maintenance and inspection.
- Preparing lighting and alarm systems whose continued use is required; de-energizing portions of fire protection, electric power, and HVAC systems whose continued use is not required.
- Cleaning of the loose surface contamination from building access pathways.
- Performing an interim radiation survey of plant, posting warning signs where appropriate.
- Erecting physical barriers and/or securing all access to radioactive or contaminated areas, except as required for inspection and maintenance.
- Installing security and surveillance monitoring equipment and relocating security fence around secured structures, as required.

2.2.2 Period 2 - Dormancy

The second phase identified by the NRC in its rule addresses licensed activities during a storage period and is applicable to the dormancy phases of the deferred decommissioning alternatives. Dormancy activities include a 24-hour security force, preventive and corrective maintenance on security systems, area lighting, general building maintenance, heating and ventilation of buildings, routine radiological inspections of contaminated structures, maintenance of structural integrity, and a site environmental and radiation monitoring program. Resident maintenance personnel perform equipment maintenance, inspection activities, routine services to maintain safe conditions, adequate lighting, heating, and ventilation, and periodic preventive maintenance on essential site services.

An environmental surveillance program is carried out during the dormancy period to ensure that releases of radioactive material to the environment are prevented and/or detected and controlled. Appropriate emergency procedures are established and initiated for potential releases that exceed prescribed limits. The environmental surveillance program constitutes an abbreviated version of the program in effect during normal plant operations.

Security during the dormancy period is conducted primarily to protect the spent nuclear fuel while it is on site, prevent unauthorized entry,

and to protect the public from the consequences of their own actions. The security fence, sensors, alarms, and other surveillance equipment provide security. Fire and radiation alarms are also monitored and maintained. While remote surveillance is an option, it does not offer the immediate response time of a physical presence.

During Scenario 6, the transfer of the spent fuel to a DOE facility continues during this period until complete. In Scenario 7, ISFSI operations and fuel transfer to the DOE continue through delayed decommissioning.

The length of the dormancy period is such that decommissioning (license termination) of the station (excluding the ISFSI) is accomplished within 60 years of final shutdown. The Scenario 6 SAFSTOR has the site remain in dormancy following spent fuel removal to the maximum extent possible, such that the licenses are terminated within the required 60-year time period.

It is required that the licensee submit an application to terminate each license, along with a LTP (described in Section 2.1.2), thereby initiating the third phase.

2.2.3 Periods 3 and 4 - Delayed Decommissioning

Prior to the commencement of decommissioning operations, preparations are undertaken to reactivate site services and prepare for decommissioning. Preparations include engineering and planning, a detailed site characterization, and the assembly of a decommissioning management organization. Final planning for activities and the writing of activity specifications and detailed procedures are also initiated at this time.

Much of the work in developing a termination plan is relevant to the development of the detailed engineering plans and procedures. The activities associated with this phase and the follow-on decontamination and dismantling processes are detailed in Sections 2.1.1 and 2.1.2. The primary difference between the sequences anticipated for the DECON and SAFSTOR scenarios is the absence, in the latter, of any constraint on the availability of the fuel storage pool located within the auxiliary building for decommissioning.

ISFSI decommissioning begins immediately upon completion of final shipment of the spent fuel and GTCC canisters.

Variations in the length of the dormancy period are expected to have some effect upon the quantities of radioactive wastes generated from system and structure removal operations. However, given the levels of radioactivity and spectrum of radionuclides expected from approximately sixty years of plant operation, no plant process system identified as being contaminated upon final shutdown will become releasable due to the decay period alone. (i.e., there is no significant reduction in the waste generated from the decommissioning activities). Due to the lower activity levels, a greater percentage of the waste volume can be designated for off-site processing and recovery.

The delay in decommissioning also yields lower working area radiation levels. As such, the estimate for the delayed scenarios incorporate reduced ALARA controls for the SAFSTOR's lower occupational exposure potential.

Although the initial radiation levels due to ^{60}Co will substantially decrease during the dormancy period, the internal components of the reactor vessels will still exhibit sufficiently high radiation dose rates to require remote sectioning under water due to the presence of long-lived radionuclides such as ^{94}Nb, ^{59}Ni, and ^{63}Ni. Therefore, the dismantling procedures described for the DECON alternative would still be employed during this scenario. Portions of the biological shield wall will still be radioactive due to the presence of activated trace elements with long half-lives (^{152}Eu and ^{154}Eu). Decontamination will require controlled removal and disposal. It is assumed that radioactive corrosion products on inner surfaces of piping and components will not have decayed to levels that will permit unrestricted use or allow conventional removal. These systems and components will be surveyed as they are removed and disposed of in accordance with the existing radioactive release criteria.

2.2.4 Period 5 - Site Restoration

Following completion of decommissioning operations, site-restoration activities can begin. Dismantling, as a continuation of the decommissioning process, is a cost-effective option, as described in Section 2.1.3. The basis for the dismantling cost in this scenario is consistent with that described for DECON, presuming the removal of structures and site facilities to include the existing foundations and basemats, and the limited restoration of the site.

3. COST ESTIMATES

The cost estimates prepared for decommissioning Prairie Island consider the unique features of the site, including the NSSS, power generation systems, support services, site buildings, and ancillary facilities. The basis of the estimates, including the sources of information relied upon, the estimating methodology employed, site-specific considerations, and other pertinent assumptions, is described in this section.

3.1 BASIS OF ESTIMATES

The estimates were developed using the site-specific, technical information from the 2014 analysis. The plant inventory, the basis for the decontamination and dismantling requirements and cost, and the decommissioning waste streams, was reviewed for this analysis; no substantive changes were identified over the three-year period to the configuration of the plant or site facilities that would impact decommissioning. The site-specific considerations and assumptions used in the previous evaluation were also revisited; no necessary modifications were identified. Modifications such as new FLEX facilities were incorporated where new information was available or experience from ongoing decommissioning programs provided viable alternatives or improved processes.

3.2 METHODOLOGY

The methodology used to develop the estimates follows the basic approach originally presented in the AIF/NESP-036 study report, "Guidelines for Producing Commercial Nuclear Power Plant Decommissioning Cost Estimates,"[24] and the DOE "Decommissioning Handbook."[25] These documents present a unit factor method for estimating decommissioning activity costs, which simplifies the estimating calculations. Unit factors for concrete removal ($/cubic yard), steel removal ($/ton), and cutting costs ($/inch) were developed using local labor rates. The activity-dependent costs were estimated with the item quantities (cubic yards and tons), developed from plant drawings and inventory documents. Removal rates and material costs for the conventional disposition of components and structures relied upon information available in the industry publication, "Building Construction Cost Data," published by RSMeans.[26]

The unit factor method provides a demonstrable basis for establishing reliable cost estimates. The detail provided in the unit factors, including activity duration, labor costs (by craft), and equipment and consumable costs, ensures

that essential elements have not been omitted. Appendix A presents the detailed development of a typical unit factor. Appendix B provides the values contained within one set of factors developed for this analysis.

Regulatory Guide 1.184 [27] describes the methods and procedures that are acceptable to the NRC staff for implementing the requirements that relate to the initial activities and the major phases of the decommissioning process. The costs and schedules presented in this analysis follow the general guidance and sequence in the regulations. The format and content of the estimates is also consistent with the recommendations of Regulatory Guide 1.202. [28]

This analysis reflects lessons learned from TLG's involvement in the Shippingport Station Decommissioning Project, completed in 1989, as well as the decommissioning of the Cintichem reactor, hot cells, and associated facilities, completed in 1997. In addition, the planning and engineering for the Pathfinder, Shoreham, Rancho Seco, Trojan, Yankee Rowe, Big Rock Point, Maine Yankee, Humboldt Bay-3, Oyster Creek, Connecticut Yankee, Crystal River, Vermont Yankee and Fort Calhoun nuclear units have provided additional insight into the process, the regulatory aspects, and the technical challenges of decommissioning commercial nuclear units.

Work Difficulty Factors

TLG has historically applied work difficulty adjustment factors (WDFs) to account for the inefficiencies in working in a power plant environment. WDFs were assigned to each unique set of unit factors, commensurate with the inefficiencies associated with working in confined, hazardous environments. The ranges used for the WDFs are as follows:

- Access Factor 10% to 20%
- Respiratory Protection Factor 10% to 50%
- Radiation/ALARA Factor 10% to 40%
- Protective Clothing Factor 10% to 30%
- Work Break Factor 8.33%

The factors and their associated range of values were developed in conjunction with the AIF/NESP-036 study. The application of the factors is discussed in more detail in that publication.

Scheduling Program Durations

The unit factors, adjusted by the WDFs as described above, are applied against the inventory of materials to be removed in the radiologically controlled areas.

The resulting man-hours, or crew-hours, are used in the development of the decommissioning program schedule, using resource loading and event sequencing considerations. The scheduling of conventional removal and dismantling activities are based upon productivity information available from the RSMeans "Building Construction Cost Data" publication. Dismantling of the fuel handing systems and decontamination of the spent fuel pool is also dependent upon the timetable for the transfer of the spent fuel assemblies from the pool to the ISFSI or the DOE.

The program schedule is used to determine the period-dependent costs for program management, administration, field engineering, equipment rental, contracted services, etc. The study relies upon regional or site-specific salary and wage rates for the personnel associated with the intended program.

3.3 IMPACT OF DECOMMISSIONING MULTIPLE REACTOR UNITS

In estimating the near simultaneous decommissioning of two co-located reactor units there can be opportunities to achieve economies of scale, by sharing costs between units, and coordinating the sequence of work activities. There will also be schedule constraints, particularly where there are requirements for specialty equipment and staff, or practical limitations on when final status surveys can take place. For purposes of the estimates, Units 1 and 2 are assumed to be essentially identical. Common facilities have been assigned to Unit 2. A summary of the principal impacts is listed below.

- The sequence of work generally follows the principal that the work is done at Unit 1 first, followed by similar work at Unit 2. This permits the experience gained at Unit 1 to be applied by the workforce at the second unit. It should be noted however, that the estimates do not consider productivity improvements at the second unit, since there is little documented experience with decommissioning two units simultaneously. The work associated with developing activity specifications and procedures can be considered essentially identical between the two units, therefore the second unit costs are assumed to be a fraction of the first unit (~ 43%).
- Segmenting the reactor vessel and internals will require the use of special equipment. The cost of procuring that equipment is assumed to be shared on an equal basis between the two units. In addition, the decommissioning project will be scheduled such that Unit 2's reactor internals and vessel are segmented immediately after the activities at Unit 1 have been completed.
- Duplication of some program management and support costs, particularly costs associated with the more senior positions, can be avoided with two reactors undergoing decommissioning simultaneously. As a result, the

estimates are based on a "lead" unit that includes these senior positions, and a "second" unit that excludes these positions. The designation as lead is based on the unit undertaking the most complex tasks (for instance vessel segmentation) or performing tasks for the first time.

- The final radiological survey schedule is also affected by a two-unit decommissioning schedule. Trying to complete the final status survey of Unit 1, while Unit 2 still has ongoing radiological remediation work and waste handling in process is considered impractical. As a result, Unit 1 and Unit 2 delay durations awaiting spent fuel pool availability for decommissioning are synchronized, such that the spent fuel pool area decommissioning and subsequent final status survey can be completed for the station. During the spent fuel storage period, program management costs are reduced accordingly.
- The final demolition of buildings at Units 1 and 2 are considered to take place concurrently.
- Unit 1, as the first unit to enter decommissioning, incurs the majority of site characterization costs.
- Shared systems and structures are generally assigned to Unit 2.
- Station costs such as ISFSI operations, emergency response fees, regulatory agency fees, and insurance are generally allocated on an equal basis between the two units.

3.4 FINANCIAL COMPONENTS OF THE COST MODEL

TLG's proprietary decommissioning cost model, DECCER, produces a number of distinct cost elements. These direct expenditures, however, do not comprise the total cost to accomplish the project goal, i.e., license termination and site restoration.

3.4.1 Contingency

Inherent in any cost estimate that does not rely on historical data is the inability to specify the precise source of costs imposed by factors such as tool breakage, accidents, illnesses, weather delays, and labor stoppages. In the DECCER cost model, contingency fulfills this role. Contingency is added to each line item to account for costs that are difficult or impossible to develop analytically. Such costs are historically inevitable over the duration of a job of this magnitude; therefore, this cost analysis includes funds to cover these types of expenses.

The activity- and period-dependent costs are combined to develop the total decommissioning cost. A contingency is then applied on a line-item basis, using one or more of the contingency types listed in the AIF/NESP-036 study. "Contingencies" are defined in the American Association of Cost Engineers "Project and Cost Engineers' Handbook"[29] as "specific provision for unforeseeable elements of cost within the defined project scope; particularly important where previous experience relating estimates and actual costs has shown that unforeseeable events which will increase costs are likely to occur." The cost elements in this analysis are based upon ideal conditions and maximum efficiency; therefore, consistent with industry practice, a contingency factor has been applied. In the AIF/NESP-036 study, the types of unforeseeable events that are likely to occur in decommissioning are discussed and guidelines are provided for percentage contingency in each category. It should be noted that contingency, as used in this analysis, does not account for price escalation and inflation in the cost of decommissioning over the remaining operating life of the station.

The use and role of contingency within decommissioning estimates is not a "safety factor issue." Safety factors provide additional security and address situations that may never occur. Contingency funds are expected to be fully expended throughout the program. They also provide assurance that sufficient funding is available to accomplish the intended tasks. An estimate without contingency, or from which contingency has been removed, can disrupt the orderly progression of events and jeopardize a successful conclusion to the decommissioning process.

For example, the most technologically challenging task in decommissioning a commercial nuclear plant is the disposition of the reactor vessels and internal components, now highly radioactive after a lifetime of exposure to core activity. The disposition of these components forms the basis of the critical path (schedule) for decommissioning operations. Cost and schedule are interdependent, and any deviation in schedule has a significant impact on cost for performing a specific activity.

Disposition of the reactor vessel internals involves the underwater cutting of complex components that are highly radioactive. Costs are based upon optimum segmentation, handling, and packaging scenarios. The schedule is primarily dependent upon the turnaround time for the heavily shielded shipping casks, including preparation, loading, and decontamination of the containers for transport. The number of casks

required is a function of the pieces generated in the segmentation activity, a value calculated on optimum performance of the tooling employed in cutting the various subassemblies. The expected optimization, however, may not be achieved, resulting in delays and additional program costs. For this reason, contingency must be included to mitigate the consequences of the expected inefficiencies inherent in this complex activity, along with related concerns associated with the operation of highly specialized tooling, field conditions, and water clarity.

Contingency funds are an integral part of the total cost to complete the decommissioning process. Exclusion of this component puts at risk a successful completion of the intended tasks and, potentially, subsequent related activities. For this study, TLG examined the major activity-related problems (decontamination, segmentation, equipment handling, packaging, transport, and waste disposal) that necessitate a contingency. Individual activity contingencies ranged from 10% to 75%, depending on the degree of difficulty judged to be appropriate from TLG's actual decommissioning experience. The contingency values used in this study are as follows:

Decontamination	50%
Contaminated Component Removal	25%
Contaminated Component Packaging	10%
Contaminated Component Transport	15%
Low-Level Radioactive Waste Disposal	25%
Reactor Segmentation	75%
NSSS Component Removal	25%
Reactor Waste Packaging	25%
Reactor Waste Transport	25%
Reactor Vessel Component Disposal	50%
GTCC Disposal	15%
Non-Radioactive Component Removal	15%
Heavy Equipment and Tooling	15%
Supplies	25%
Engineering	15%
Energy	15%
Characterization and Termination Surveys	30%
Construction	15%
Asbestos	15%

Taxes and Fees	10%
Insurance	10%
Staffing	15%
Spent Fuel Storage (Dry) Systems	15%
Spent Fuel Transfer Costs	15%
Operations and Maintenance Expenses	15%
ISFSI Decommissioning	25%

The contingency values are applied to the appropriate components of the estimates on a line item basis. A composite value is then reported at the end of each detailed estimate (as provided in Appendices C through I). Appendix J, the ISFSI decommissioning calculation, uses a flat 25% contingency added at the end of the calculation.

3.4.2 Financial Risk

In addition to the routine uncertainties addressed by contingency, another cost element that is sometimes necessary to consider when bounding decommissioning costs relates to uncertainty, or risk. Examples can include changes in work scope, pricing, job performance, and other variations that could conceivably, but not necessarily, occur. Consideration is sometimes necessary to generate a level of confidence in the estimate, within a range of probabilities. TLG considers these types of costs under the broad term "financial risk." Included within the category of financial risk are:

- Transition activities and costs: ancillary expenses associated with eliminating 50% to 80% of the site labor force shortly after the cessation of plant operations, added cost for worker separation packages throughout the decommissioning program, national or company-mandated retraining, and retention incentives for key personnel.
- Delays in approval of the decommissioning plan due to intervention, public participation in local community meetings, legal challenges, and national and local hearings.
- Changes in the project work scope from the baseline estimate, involving the discovery of unexpected levels of contaminants, contamination in places not previously expected, contaminated soil previously undiscovered (either radioactive or hazardous material contamination), variations in plant inventory or configuration not indicated by the as-built drawings.

- Regulatory changes (e.g., affecting worker health and safety, site release criteria, waste transportation, and disposal).
- Policy decisions altering national commitments (e.g., in the ability to accommodate certain waste forms for disposition) or in the timetable for such, for example, the start and rate of acceptance of spent fuel by the DOE.
- Pricing changes for basic inputs such as labor, energy, materials, and disposal. Items subject to widespread price competition (such as materials) may not show significant variation; however, others such as waste disposal could exhibit large pricing uncertainties, particularly in markets where limited access to services is available.

This cost study does not add any additional costs to the estimate for financial risk, since there is insufficient historical data from which to project future liabilities. Consequently, the areas of uncertainty or risk are revisited periodically and addressed through repeated revisions or updates of the base estimates.

3.5 SITE-SPECIFIC CONSIDERATIONS

There are a number of site-specific considerations that affect the method for dismantling and removal of equipment from the site and the degree of restoration required. The cost impacts of the considerations identified below are included in this cost study.

3.5.1 Spent Fuel Management

The cost to dispose of spent fuel generated from plant operations is not reflected within the estimates to decommission Prairie Island. Ultimate disposition of the spent fuel is within the province of the DOE's Waste Management System, as defined by the Nuclear Waste Policy Act. As such, the disposal cost was financed by a 1 mill/kWhr surcharge paid into the DOE's waste fund during operations. On November 19, 2013, the U.S. Court of Appeals for the D.C. Circuit ordered the Secretary of the Department of Energy to suspend collecting annual fees for nuclear waste disposal from nuclear power plant operators until the DOE has conducted a legally adequate fee assessment.

The NRC does, however, require licensees to establish a program to manage and provide funding for the management of all irradiated fuel at the reactor site until title of the fuel is transferred to the Secretary of

Energy. This requirement is prepared for through inclusion of certain high-level waste cost elements within the estimates, as described below.

Xcel Energy's current spent fuel management plan for the Prairie Island spent fuel is based in general upon:

1) Fuel transferred from the pool to the ISFSI within 5 years of shutdown;
2) Exchange of Prairie Island and Monticello spent fuel acceptance rights to best manage the overall cost of spent fuel storage for both plants;
3) Fuel will be shipped in the existing Transnuclear TN-40 casks, plus NUHOMS DSCs for fuel removed after final plant shutdown (Scenarios 1, 2, 6, and 7); the canisters and NUHOMS are periodically replaced in Scenarios 3, 4 and 5. Spent fuel assemblies from TN-40 casks that are replaced will be put into NUHOMS DSCs. Canisters that are unloaded in the spent fuel transfer operation will be surveyed for neutron activation.
4) As an allowance, some of these canisters and NUHOMS modules from the first off-load operation are assumed to be mildly neutron activated and therefore must be disposed of as radioactive waste.

This analysis assumes that the existing ISFSI is modified at the cessation of plant operations to accommodate the fuel present in the storage pool at shutdown.

The DOE's repository program assumes that spent fuel will be accepted for disposal from the nation's commercial nuclear plants in the order (the "queue") in which it was removed from service ("oldest fuel first").[31] Repository operations were based upon annual industry-wide receipt of 400 Metric Tons Heavy Metal (MTHM) in the first year of operation, a total of 3,800 MTHM in years 2 through 4 and 3,000 MTHM for year 5 and beyond.[32] This logic supports the spent fuel schedules for Scenarios 1 and 6. All other spent fuel scenarios are consistent with those identified by the Minnesota PSC.

Operation and maintenance costs for the spent fuel pool and ISFSI are included within the estimates and address the costs for staffing the facility, as well as security, insurance, and licensing fees. The estimates also include the costs to purchase, load, and transfer the NUHOMs DSCs from the pool to the ISFSI. Costs are also provided for the final

disposition of the ISFSI once the transfer of the TN-40s and DSCs from the ISFSI to the DOE is complete.

Storage Canister Design

The design and capacity of the ISFSI is based upon the Transnuclear NUHOMS system (with a 61-fuel assembly capacity). The system consists of a multi-purpose (storage and transport) dry shielded storage canister (DSC) and a horizontal storage module (HSM). The existing TN-40 casks will remain in the ISFSI until either shipment to the DOE, or until recasked.

Canister Loading and Transfer

The estimates include an average cost of $1,000,000 for the labor to load/transport the spent fuel from the pool to the ISFSI pad. For estimating purposes an allowance of $332,800 is used for the cost to transfer each fuel canister from the ISFSI pad to the DOE transport vehicle.

Operations and Maintenance

An annual cost (excluding labor) of approximately $803,000 and $103,000 are used for operation and maintenance of the spent fuel pool and the ISFSI, respectively.

At shutdown, the spent fuel pool is expected to contain freshly discharged assemblies (from the most recent refueling cycles). Over the next five years the assemblies are packaged into DSCs for transfer to the ISFSI for transfer to the DOE. It is assumed that the five years provides the necessary cooling period for the final cores to meet the decay heat requirements for dry storage. Once the pool is emptied, the spent fuel storage and handling facilities are available for decommissioning.

Replacement of DSCs during ISFSI fuel storage period

Scenarios 1, 2, 6, and 7 do not assume any replacement of the spent fuel storage DSCs (recasking).

Three of the cost estimates, Scenarios 3, 4 and 5, include costs to recask the spent fuel, based upon an assumption that the DSC has a limited lifetime of approximately 50 years.

Scenario 3, which is 100 years (nominally) in length, considers a single repackaging effort for each DSC in the ISFSI.

Scenario 4, which is a (nominal) 200-year scenario, assumes that when any DSC in the ISFSI reaches the 50 years of storage milestone, the DSC is replaced. In Scenario 4, the fuel will be recasked three times following final shutdown of Prairie Island.

Scenario 5, which is 60 years (nominally) in length, considers a single repackaging effort for each DSC in the ISFSI. Not all fuel will be recasked.

Since the auxiliary building, spent fuel storage pool, and fuel handling facilities are removed by the year 2040, a dry fuel transfer facility is assumed to be constructed on site to perform the transfers from the old to the new DSCs. Scenarios 3, 4 and 5 include the cost to construct such a transfer facility, as well as additional staffing positions for support of the dry transfer activities, and additional NRC oversight associated with the transfer operations. The decommissioning of this transfer facility is also included in Scenarios 3, 4 and 5.

ISFSI Decommissioning

In accordance with 10 CFR §72.30, licensees must have a proposed decommissioning plan for the ISFSI site and facilities that includes a cost estimate for the plan. The plan should contain sufficient information on the proposed practices and procedures for the decontamination of the ISFSI and for the disposal of residual radioactive materials after all spent fuel, high-level radioactive waste, and reactor-related GTCC waste have been removed.

The NUHOMS multi-purpose dry shielded storage canister with a horizontal, reinforced concrete storage module is used as a basis for the ISFSI decommissioning cost analyses. The modules are assumed to have some level of neutron-induced activation, as a result of the long-term storage of the fuel, i.e., to levels exceeding free-release limits. As an allowance, 8 modules are assumed to require remediation, equivalent to the number of modules required to accommodate the final core offloads at Prairie Island (121 assemblies per unit). The cost of the disposition of this material, as well as the demolition of the ISFSI facility, is included in the estimates.

The existing ISFSI pad, supporting the TN-40 casks, is not expected to be contaminated and will be demolished accordingly after a confirmation survey.

In accordance with the specific requirements of 10 CFR §72.30 for the ISFSI work scope, the cost estimate for decommissioning the ISFSI reflects: 1) the cost of an independent contractor performing the decommissioning activities; 2) an adequate contingency factor; and 3) the cost of meeting the criteria for unrestricted use. The cost summary for decommissioning the ISFSI is presented in Appendix J. It contains four different scenarios reflecting the different number of casks present at the end of the ISFSI operations. The demolition of the ISFSI for all seven scenarios is reflected within the estimates.

GTCC

The dismantling of the reactor internals is expected to generate radioactive waste considered unsuitable for shallow land disposal (i.e., low-level radioactive waste with concentrations of radionuclides that exceed the limits established by the NRC for Class C radioactive waste (GTCC)). Although the material is not classified as high-level waste, federal regulations under the LLRW Policy Amendments Act specifies the GTCC LLRW is designated a federal responsibility under Section 3(b)(1)(D). However, the DOE has not been forthcoming with an acceptance criteria or disposition schedule for this material, and numerous questions remain as to the ultimate disposal cost and waste form requirements. As such, for purposes of this study, the GTCC has been packaged and disposed of in the same manner as high-level waste, at a cost equivalent to that envisioned for the spent fuel. This is consistent with the concept that the generator of GTCC waste will bear all reasonable costs of disposing of such wastes. [32]

The number of DSCs required and the packaged volume for GTCC was based upon experience at Maine Yankee (e.g., the constraints on loading as identified in the canister's certificate of compliance), but adjusted for the increased spent fuel capacity of the 32 assembly DSCs.

It is assumed that the DOE would not accept this waste prior to completing the transfer of spent fuel. Therefore, until such time the DOE is ready to accept GTCC waste, it is reasonable to assume that this material would remain in storage at Prairie Island (for the DECON alternatives). In the SAFSTOR alternatives, the GTCC material is shipped directly to a DOE facility as it is generated. GTCC costs have

been segregated and included within the "License Termination" expenditures.

3.5.2 Reactor Vessel and Internal Components

The reactor pressure vessel and internal components are segmented for disposal in shielded, reusable transportation casks. Segmentation is performed underwater in the refueling canal, where a turntable and remote cutter are installed. The vessels are segmented in place, using a mast-mounted cutter supported off the lower head and directed from a shielded work platform installed overhead in the reactor cavity. Transportation cask specifications and transportation regulations dictate the segmentation and packaging methodology. The control elements are disposed of along with the spent fuel; there is no additional cost provided for their disposal.

Intact disposal of reactor vessel shells has been successfully demonstrated at several of the sites that have been decommissioned. Access to navigable waterways has allowed these large packages to be transported to the Barnwell disposal site with minimal overland travel. Intact disposal of the reactor vessel and internal components can provide savings in cost and worker exposure by eliminating the complex segmentation requirements, isolation of the GTCC material, and transport/storage of the resulting waste packages. Portland General Electric (PGE) was able to dispose of the Trojan reactor as an intact package (including the internals). However, its location on the Columbia River simplified the transportation analysis since:

- the reactor package could be secured to the transport vehicle for the entire journey, i.e., the package was not lifted during transport,
- there were no man-made or natural terrain features between the plant site and the disposal location that could produce a large drop, and
- transport speeds were very low, limited by the overland transport vehicle and the river barge.

As a member of the Northwest Compact, PGE had a site available for disposal of the package - the US Ecology facility in Washington State. The characteristics of this arid site proved favorable in demonstrating compliance with land disposal regulations.

It is not known whether this option will be available when Prairie Island ceases operation. Future viability of this option will depend upon the ultimate location of the disposal site, as well as the disposal site licensee's ability to accept highly radioactive packages and effectively isolate them from the environment. As such, the estimates assume segmentation of the reactor vessel, as a bounding condition. With lower levels of activation, the vessel shell can be packaged more efficiently than the curie-limited internal components. This will allow the use of more conventional waste packages rather than shielded casks for transport.

3.5.3 Primary System Components

The reactor coolant system components are assumed to be decontaminated using chemical agents prior to the start of cutting operations. This type of decontamination can be expected to have a significant ALARA impact in the DECON scenario, since in this scenario the removal work is done within the first few years of shutdown. A decontamination factor (average reduction) of 10 is assumed for the process. Disposal of the decontamination solution effluent is included within the estimate as a "process liquid waste" charge. The SAFSTOR scenarios do not include any decontamination of the reactor system; radioactive decay from the delay period in the dormancy results in similar results.

The following discussion deals with the removal and disposition of the steam generators, but the techniques involved are also applicable to other large radioactively-contaminated components, such as heat exchangers, component coolers, and the pressurizer. The steam generators' size and weight, their location within the reactor building, as well as the disposal facility waste acceptance criteria, and access to transportation will ultimately determine the removal, transportation, and disposal strategy.

A trolley crane is set up for the removal of the generators. It can also be used to move portions of the steam generator cubicle walls and floor slabs from the reactor building to a location where they can be decontaminated and transported to the material handling area. Interferences within the work area, such as grating, piping, and other components are removed to create sufficient lay-down space for processing these large components.

The generators are rigged for removal, disconnected from the surrounding piping and supports, and maneuvered into the open area where they are lowered onto a down-ending cradle. Each generator is rotated into the horizontal position for extraction from the containment and placed onto a multi-wheeled vehicle for transport to an on-site preparation area.

The generators are disassembled on-site with the outer shell and lightly contaminated subassemblies designated for off-site recycling. The more highly contaminated tube sheet and tube bundle are packaged for direct disposal.

Disposal costs are based upon the displaced volume and weight of the primary side portions of the steam generators. Each component is then loaded onto a rail car for transport to the disposal facility. The secondary side is assumed to be sent to an off-site waste processor.

Reactor coolant piping is cut from the reactor vessel once the water level in the vessel (used for personnel shielding during dismantling and cutting operations in and around the vessel) is dropped below the nozzle zone. The piping is boxed and transported by shielded van. The reactor coolant pumps and motors are lifted out intact, packaged, and transported for processing and/or disposal.

3.5.4 Main Turbine and Condenser

The main turbine and condenser are assumed to have only minor levels of contamination. As such, the components are dismantled using conventional maintenance procedures. The turbine rotors and shafts will be removed to a laydown area. The lower turbine casings will be removed from their anchors by controlled demolition. The main condensers will also be disassembled and moved to a laydown area. Material is then prepared for transportation to an off-site recycling facility where it will be surveyed and designated for either decontamination or volume reduction, or controlled disposal. Components will be packaged and readied for transport in accordance with the intended disposition.

3.5.5 Transportation Methods

Contaminated piping, components, and structural material other than the highly activated reactor vessels and internal components will qualify as LSA-I, II or III or Surface Contaminated Object, SCO-I or II, as

described in Title 49. [34] The contaminated material will be packaged in Industrial Packages (IP-1, IP-2, or IP-3, as defined in subpart 173.411) for transport unless demonstrated to qualify as their own shipping containers. The reactor vessel and internal components are expected to be transported in accordance with 10 CFR Part 71, as Type B. It is conceivable that the reactor, due to its limited specific activity, could qualify as LSA II or III. However, the high radiation levels on the outer surface would require that additional shielding be incorporated within the packaging so as to attenuate the dose to levels acceptable for transport.

Any fuel cladding failure that occurred during the lifetime of the plant is assumed to have released fission products at sufficiently low levels that the buildup of quantities of long-lived isotopes (e.g., ^{137}Cs, ^{90}Sr, or transuranics) has been prevented from reaching levels exceeding those that permit the major reactor components to be shipped under current transportation regulations and disposal requirements.

Transport of the highly activated metal, produced in the segmentation of the reactor vessel and internal components, will be by shielded truck cask. Cask shipments may exceed 95,000 pounds, including vessel segment(s), supplementary shielding, cask tie-downs, and tractor-trailer. The maximum level of activity per shipment assumed permissible was based upon the license limits of the available shielded transport casks. The segmentation scheme for the vessel and internal segments is designed to meet these limits.

The transport of large intact components (e.g., large heat exchangers and other oversized components) will be by a combination of truck, rail, and/or multi-wheeled transporter. Transportation costs for Class A radioactive material requiring controlled disposal are based upon the mileage to the Energy*Solutions* facility in Clive, Utah. Transportation costs for the higher activity Class B and C radioactive material are based upon the mileage to the WCS facility in Andrews County, Texas. The transportation cost for the GTCC material is assumed to be contained within the disposal cost. Transportation costs for off-site waste processing are based upon the mileage to Oak Ridge, Tennessee. Truck transport costs were estimated using published tariffs from Tri-State Motor Transit. [35]

3.5.6 Low-Level Radioactive Waste Disposal

To the greatest extent practical, metallic material generated in the decontamination and dismantling processes is processed to reduce the total cost of controlled disposal. Material meeting the regulatory and/or site release criterion, is released as scrap, requiring no further cost consideration. Conditioning (preparing the material to meet the waste acceptance criteria of the disposal site) and recovery of the waste stream is performed off site at a licensed processing center. Any material leaving the site is subject to a survey and release charge, at a minimum.

The mass of radioactive waste generated during the various decommissioning activities at the site is shown on a line-item basis in the detailed Appendices C through J, and summarized in Section 5. The quantified waste summaries shown in these tables are consistent with 10 CFR Part 61 classifications. Commercially available steel containers are presumed to be used for the disposal of piping, small components, and concrete. Larger components can serve as their own containers, with proper closure of all openings, access ways, and penetrations. The volumes are calculated based on the exterior package dimensions for containerized material or a specific calculation for components serving as their own waste containers.

The more highly activated reactor components will be shipped in reusable, shielded truck casks with disposable liners. In calculating disposal costs, the burial fees are applied against the liner volume and weight, with surcharges added for the special handling requirements and the radiological characteristics of the payload. Packaging efficiencies are lower for the highly activated materials (greater than Type A quantity waste), where high concentrations of gamma-emitting radionuclides limit the capacity of the shipping canisters.

The cost to dispose of the lowest level and majority of the material generated from the decontamination and dismantling activities is based upon representative costs for disposal at Energy*Solutions* facility in Clive, Utah. Disposal costs for the higher activity waste (Class B and C) were based upon preliminary and indicative information from WCS for the Andrews County facility

Material exceeding Class C limits (limited to material closest to the reactor core and comprising less than 1% of the total waste volume) is generally not suitable for shallow-land disposal. This material is

packaged in the same multipurpose canisters used for spent fuel storage/transport, for eventual transfer to the DOE for disposal.

3.5.7 Site Conditions Following Decommissioning

The NRC will amend or terminate each unit's license if it determines that site remediation has been performed in accordance with the license termination plan, and that the terminal radiation survey and associated documentation demonstrate that the facility is suitable for release. The NRC's involvement in the decommissioning process will end at this point. Building codes and environmental regulations will dictate the next step in the decommissioning process, as well as Xcel Energy's own future plans for the site, e.g., the electrical switchyard will remain in support of the regional transmission and distribution system.

Asphalt surfaces in the immediate vicinity of site buildings are broken up and the material disposed of as construction debris. The site access road will remain.

Only existing site structures are considered in the dismantling cost. All subgrade structures are removed. The voids are backfilled with clean debris and capped with soil. The site is then re-graded to conform to the adjacent landscape. Vegetation is established to inhibit erosion. These "non-radiological costs" are included in the total cost of decommissioning.

Bulk excavation of soil and material in the immediate vicinity of the power block is included to remove various duct banks, catch basins, and underground utilities that may exist.

The estimates do not assume the remediation of any significant volume of contaminated soil. This assumption may be affected by continued plant operations and/or future regulatory actions, such as the development of site-specific release criteria.

3.6 ASSUMPTIONS

The following are the major assumptions made in the development of the estimates for decommissioning the site.

3.6.1 Estimating Basis

The study follows the principles of ALARA through the use of work duration adjustment factors. These factors address the impact of

activities such as radiological protection instruction, mock-up training, and the use of respiratory protection and protective clothing. The factors lengthen a task's duration, increasing costs and lengthening the overall schedule. ALARA planning is considered in the costs for engineering and planning, and in the development of activity specifications and detailed procedures. Changes to worker exposure limits may impact the decommissioning cost and project schedule.

3.6.2 Labor Costs

For purposes of this analysis, it is assumed that Xcel Energy will hire a Decommissioning Operations Contractor (DOC) to manage the decommissioning. Xcel Energy will provide site security, radiological health and safety, quality assurance and overall site administration during the decommissioning and demolition phases. Contract personnel will provide engineering services (e.g., for preparing the activity specifications, work procedures, neutron activation, and structural analyses) under the direction of Xcel Energy.

Utility labor costs were provided by Xcel Energy. Average costs were provided by department or work group and included payroll overheads. Decommissioning Operations Contractor (DOC) labor costs were based on utility labor costs with modified markups to account for employee benefits, DOC overhead and profit.

The craft labor required to decontaminate and dismantle the nuclear station will be acquired through standard site contracting practices. Craft labor costs were based upon information from Xcel Energy. Craft labor costs include applicable overheads and profit.

Security, while reduced from operating levels, is maintained throughout the decommissioning for access control, material control, and to safeguard the spent fuel.

Staffing levels are assigned by sub-period and functional area. Economies of a multi-unit decommissioning are recognized by establishing a primary and a secondary staff level. The unit assigned the primary staff will include common supervisory positions and positions that may be shared across both units. The types of positions and staffing levels are adjusted based upon the type of activity occurring in each sub-period.

Representative profiles of the staffing level for decommissioning, including contractors and craft, is provided in Figures 3.1 and 3.2 for the DECON (Scenario 2) and SAFSTOR (Scenario 7) estimates. Utility staffing levels will gradually decrease after completing the removal of physical systems. Staffing levels and management support will vary based upon the amount and type of decommissioning work. Craft manpower levels decrease after systems removal and structures decontamination and drop substantially during the delay period and the license termination survey period. However, craft levels increase again during the site restoration period due to the work associated with structures demolition. During SAFSTOR dormancy, following transfer of the spent fuel to the ISFSI, staffing levels for the power block are reduced to a minimum, then rise as the delayed dismantling operations begin.

Security, while reduced from operating levels, is maintained throughout the decommissioning for access control, material control, and to safeguard the spent fuel (in accordance with the requirements of 10 CFR Part 37, Part 72, and Part 73). Once the fuel has been transferred to the DOE, the security organization will be reduced to Part 37 requirements for Scenario 6.

3.6.3 Design Conditions

Any fuel cladding failure that occurred during the lifetime of the plant is assumed to have released fission products at sufficiently low levels that the buildup of quantities of long-lived isotopes (e.g., ^{137}Cs, ^{90}Sr, or transuranics) has been prevented from reaching levels exceeding those that permit the major NSSS components to be shipped under current transportation regulations and disposal requirements.

The curie contents of the vessels and internals at final shutdown are derived from those listed in NUREG/CR-3474.[35] Actual estimates are derived from the curie/gram values contained therein and adjusted for the different mass of the Prairie Island components, projected operating life, and different periods of decay. Additional short-lived isotopes were derived from NUREG/CR-0130[36] and NUREG/CR-0672,[37] and benchmarked to the long-lived values from NUREG/CR-3474.

It is anticipated that there will be control element assemblies (CEAs) in the spent fuel pool at the cessation of operations, including those CEAs from the final core. This analysis assumes that the CEAs can be

disposed of along with the spent fuel at no additional cost (in accordance with Appendix E of the Standard Contract [38])

Neutron activation of the reactor building structure is confined to the reactor biological shield.

3.6.4 General

Transition Activities

Existing warehouses will be cleared of non-essential material and remain for use by Xcel Energy and subcontractors. The plant's operating staff will perform the following activities at no additional cost or credit to the project during the transition period:

- Drain and collect fuel oils, lubricating oils, and transformer oils for recycle and/or sale.
- Drain and collect acids, caustics, and other chemical stores for recycle and/or sale.
- Processes operating waste inventories, i.e., the estimates do not address the disposition of any legacy wastes; the disposal of operating wastes during this initial period is not considered a decommissioning expense.

Scrap and Salvage

The existing plant equipment is considered obsolete and suitable for scrap as deadweight quantities only. Xcel Energy will make economically reasonable efforts to salvage equipment following final plant shutdown. However, dismantling techniques assumed by TLG for equipment in this analysis are not consistent with removal techniques required for salvage (resale) of equipment. Experience has indicated that some buyers wanted equipment stripped down to very specific requirements before they would consider purchase. This required expensive rework after the equipment had been removed from its installed location. Since placing a salvage value on this machinery and equipment would be speculative, and the value would be small in comparison to the overall decommissioning expenses, this analysis does not attempt to quantify the possible salvage value that Xcel Energy may realize based upon those efforts.

It is assumed, for purposes of this analysis, that any value received from the sale of scrap generated in the dismantling process would be offset by the on-site processing costs. The dismantling techniques assumed in the decommissioning estimates do not include the additional cost for size reduction and preparation to meet "furnace ready" conditions. For example, the recovery of copper from electrical cabling may require the removal and disposition of any contaminated insulation, an added expense. With a volatile market, the potential profit margin in scrap recovery is highly speculative, regardless of the ability to free release this material. This assumption is an implicit recognition of scrap value in the disposal of clean metallic waste at no additional cost to the project.

Furniture, tools, mobile equipment such as forklifts, trucks, bulldozers, and other property will be removed at no cost or credit to the decommissioning project. Disposition may include relocation to other facilities. Spare parts will also be made available for alternative use.

The concrete debris resulting from building demolition activities is crushed on site to reduce the size of the debris. The resulting crushed concrete is disposed offsite as construction debris. The rebar removed from the concrete crushing process is disposed of as scrap steel in a similar fashion as other scrap metal as discussed previously.

Asbestos

At the time of Prairie Island's construction, asbestos was still being used for system component and piping insulation, and as fireproofing material for structures. No inventory of asbestos at Prairie Island was available, so TLG developed an estimated quantity. The allowance for the remediation of this asbestos is captured in the detailed cost analyses (Appendices C through I).

Energy

For estimating purposes, the plant is assumed to be de-energized, with the exception of those facilities associated with spent fuel storage. Replacement power costs are used for the cost of energy consumption during decommissioning for tooling, lighting, ventilation, and essential services.

Emergency Planning

FEMA and state fees associated with emergency planning are assumed to continue for approximately 18 months following the cessation of operations. At this time, the FEMA fees are discontinued. The timing is based upon the anticipated condition of the spent fuel (i.e., the hottest spent fuel assemblies are assumed to be cool enough that no substantial Zircaloy oxidation and off-site event would occur with the loss of spent fuel pool water). State and local fees are continued until all spent fuel is transferred out of the spent fuel pool.

Insurance

Costs for continuing coverage (nuclear liability and property insurance) following cessation of plant operations and during decommissioning are included and based upon current operating premiums. Reductions in premiums throughout the decommissioning process are based upon guidance provided by Xcel Energy. Reductions in premiums, throughout the decommissioning process, are based upon the guidance provided in SECY-00-0145, "Integrated Rulemaking Plan for Nuclear Power Plant Decommissioning."[39] The NRC's financial protection requirements are based on various reactor (and spent fuel) configurations.

Xcel Energy Corporate Overhead

Corporate overhead charges for site support activities are not included in these estimates.

Site Non-Labor Overhead

These estimates include costs for site non-labor overhead charges. These costs include telephones, copy machines, computers, IT infrastructure, office supplies, janitorial supplies, training expenses, etc. Xcel Energy provided a two-part cost to address these costs. A variable charge of $3,936 per person per year of the Xcel Energy staff is included throughout the estimate. A fixed annual overhead charge is also included, starting at $1.5 million per reactor at the time of unit shut down and decreasing to approximately $467 thousand per reactor.

Taxes

Property taxes are included for all decommissioning periods. Xcel Energy provided a schedule of decreasing tax payments against the

current tax assessment. These payments are maintained for the balance of the decommissioning program.

NRC Fees

These estimates include charges from the NRC to support the Prairie Island decommissioning program. Charges are included for the yearly license held by Xcel Energy for the Part 50 licenses, as well as engineering support charges by the NRC to review activities at the site. The Part 50 license fee for a reactor in a decommissioning or possession-only status and which has spent fuel onsite is $194 thousand per year. Once the reactors have been decommissioned, the site Part 50 license continues at the same fee until final removal of the spent fuel. The hourly rate for NRC review is $267.00. The level of effort of NRC participation is commensurate with the decommissioning alternative and schedule. For example, Scenario 2 has an estimated NRC support requirement of approximately 16,800 hours from Unit 1 shutdown until termination of the ISFSI license

Disposal of Processed Water

This estimate assumes that processed water which meets state and federal release limits can be disposed of without additional cost.

Site Modifications

The perimeter fence and in-plant security barriers will be moved, as appropriate, to conform to the Site Security Plan in force during the various stages of the project.

Prairie Island Indian Community Payments

This estimate includes a $2.5 million annual payment to the Prairie Island Indian Community while spent fuel is still on the Prairie Island site.

Minnesota state regulations regarding concrete

This estimate complies with the Minnesota state regulations regarding the removal of all subterranean concrete during demolition, plus the survey and confirmation of the suitability of the clean fill used for backfill of the subgrade structures following concrete removal.

3.7 COST ESTIMATE SUMMARY

The estimates presented in this document reflects the total cost to decontaminate the nuclear units, manage the spent fuel until the DOE is able to complete the transfer to a federal facility, dismantle the plant and restore the site for alternative use.

Schedules of expenditures are provided in Tables 3.1 through 3.14. The tables delineate the cost contributors by year of expenditures as well as cost contributor (e.g., labor, materials, and waste disposal).

Additional tables in Appendices C through I provide detailed costs elements. The cost elements are also assigned to one of three subcategories: "License Termination," "Spent Fuel Management," and "Site Restoration." The subcategory "License Termination" is used to accumulate costs that are consistent with "decommissioning" as defined by the NRC in its financial assurance regulations (i.e., 10 CFR §50.75). In situations where the long-term management of spent fuel is not an issue, the cost reported for this subcategory is generally sufficient to terminate each unit's operating license, recognizing that there may be some additional cost impact from spent fuel management.

The "Spent Fuel Management" subcategory contains costs associated with the containerization and transfer of spent fuel from the pool to the DOE or to the ISFSI for interim storage, and the transfer of the multipurpose canisters from the ISFSI to the DOE. Costs are also included for the operations of the pool and management of the ISFSI until such time that the transfer of all fuel from this facility to an off-site location (e.g., interim storage facility) is complete.

"Site Restoration" is used to capture costs associated with the dismantling and demolition of buildings and facilities demonstrated to be free from contamination. This includes structures never exposed to radioactive materials, as well as those facilities that have been decontaminated to appropriate levels. Structures are completely removed, including foundations and basemats and backfilled to conform to local grade.

As discussed in Section 3.5.1, it is assumed that the DOE will not accept the GTCC waste prior to completing the transfer of spent fuel. Therefore, the cost of GTCC disposal is shown in the final year of ISFSI operation (for the DECON alternative). While designated for disposal at a federal facility along with the spent fuel, GTCC waste is still classified as low-level radioactive waste and, as such, included as a "License Termination" expense.

Decommissioning costs are reported in 2017 dollars. Costs are not inflated, escalated, or discounted over the period of expenditure (or projected lifetime of the plant).

4. SCHEDULE ESTIMATE

The schedules for the decommissioning scenarios considered in this study follow the sequence presented in the AIF/NESP-036 study, with minor changes to reflect recent experience and site-specific constraints. In addition, the scheduling has been revised to reflect the spent fuel management plans described in Section 3.4.1.

A schedule or sequence of activities for the DECON alternative is presented in Figure 4.1. The schedule is also representative of the work activities identified in the delayed dismantling scenarios, absent any spent fuel constraints. The scheduling sequence is based on the fuel being removed from the spent fuel pool within the first five years after operations cease. The key activities listed in the schedule do not reflect a one-to-one correspondence with those activities in the cost tables, but reflect dividing some activities for clarity and combining others for convenience. The schedule was prepared using the "Microsoft Project Professional" computer software.[40]

4.1 SCHEDULE ESTIMATE ASSUMPTIONS

The schedule reflects the results of a precedence network developed for the site decommissioning activities, i.e., a PERT (Program Evaluation and Review Technique) Software Package. The work activity durations used in the precedence network reflect the actual man-hour estimates from the cost table, adjusted by stretching certain activities over their slack range and shifting the start and end dates of others. The following assumptions were made in the development of the decommissioning schedule:

- The fuel handling area of the auxiliary building is isolated until such time that all spent fuel has been discharged from the storage pool to the DOE or to the ISFSI. Decontamination and dismantling of the spent fuel storage pool is initiated once the transfer of spent fuel is complete (DECON option).
- All work (except vessel and internals removal) is performed during an 8-hour workday, 5 days per week, with no overtime. There are eleven paid holidays per year.
- Reactor and internals removal activities are performed by using separate crews for different activities working on different shifts, with a corresponding backshift charge for the second shift.
- Multiple crews work parallel activities to the maximum extent possible, consistent with optimum efficiency, adequate access for cutting, removal and laydown space, and with the stringent safety measures necessary during demolition of heavy components and structures.

- For plant systems removal, the systems with the longest removal durations in areas on the critical path are considered to determine the duration of the activity.

4.2 PROJECT SCHEDULE

The period-dependent costs presented in the detailed cost tables are based upon the durations developed in the schedules for decommissioning Prairie Island. Durations are established between several milestones in each project period; these durations are used to establish a critical path for the entire project. In turn, the critical path duration for each period is used as the basis for determining the period-dependent costs. A second parallel path is also shown for the spent fuel cooling period, which determines the release of the auxiliary building for final decontamination.

Project timelines are provided in Figures 4.2 through 4.8, with milestone dates based on a 2033/2034 shutdown dates. The fuel pool is emptied approximately five years after shutdown, while ISFSI operations continue until the DOE completes the transfer of assemblies. Deferred decommissioning operations in the SAFSTOR scenarios are assumed to commence so that the operating licenses are terminated within a 60-year period from the cessation of operations

5. RADIOACTIVE WASTES

The objectives of the decommissioning process are the removal of all radioactive material from the site that would restrict its future use and the termination of the NRC licenses. This currently requires the remediation of all radioactive material at the site in excess of applicable legal limits. Under the Atomic Energy Act,[41] the NRC is responsible for protecting the public from sources of ionizing radiation. Title 10 of the Code of Federal Regulations delineates the production, utilization, and disposal of radioactive materials and processes. In particular, Part 71 defines radioactive material as it pertains to transportation and Part 61 specifies its disposition.

Most of the materials being transported for controlled burial are categorized as Low Specific Activity (LSA) or Surface Contaminated Object (SCO) materials containing Type A quantities, as defined in 49 CFR Parts 173-178. Shipping containers are required to be Industrial Packages (IP-1, IP-2 or IP-3, as defined in 10 CFR §173.411). For this study, commercially available steel containers are presumed to be used for the disposal of piping, small components, and concrete. Larger components can serve as their own containers, with proper closure of all openings, access ways, and penetrations.

The destinations for the various waste streams from decommissioning are identified in Figures 5.1 and 5.2. The volumes of radioactive waste generated during the various decommissioning activities at the site are shown on a line-item basis in Appendices C through J and summarized in Tables 5.1 through 5.7. The quantified waste volume summaries shown in these tables are consistent with §61 classifications. The volumes are calculated based on the exterior dimensions for containerized material and on the displaced volume of components serving as their own waste containers.

The reactor vessel and internals are categorized as large quantity shipments and, accordingly, will be shipped in reusable, shielded truck casks with disposable liners. In calculating disposal costs, the burial fees are applied against the liner volume, as well as the special handling requirements of the payload. Packaging efficiencies are lower for the highly activated materials (greater than Type A quantity waste), where high concentrations of gamma-emitting radionuclides limit the capacity of the shipping canisters.

No process system containing/handling radioactive substances at shutdown is presumed to meet material release criteria by decay alone, i.e., systems radioactive at shutdown will still be radioactive over the time period during which the decommissioning is accomplished, due to the presence of long-lived radionuclides.

While the dose rates decrease with time, radionuclides such as ^{137}Cs will still control the disposition requirements.

The waste material generated in the decontamination and dismantling of Prairie Island is primarily generated during Period 2 of the DECON alternatives and Period 4 of the SAFSTOR alternatives. Material that is considered potentially contaminated when removed from the radiologically controlled area is sent to processing facilities in Tennessee for conditioning and disposal. Heavily contaminated components and activated materials are routed for controlled disposal. The disposal volumes reported in the tables reflect the savings resulting from reprocessing and recycling.

Disposal fees are calculated using representative costs, with surcharges added for the highly activated components, for example, generated in the segmentation of the reactor vessels. The cost to dispose of the majority of the material generated from the decontamination and dismantling activities is based upon representative rates.

Energy*Solutions* is not able to accept the higher activity waste (Class B and C) generated in the decontamination of the NSSS and segmentation of the components closest to the core. Waste disposal costs for the higher activity waste (Class B and C) are based upon preliminary and indicative information on the cost for such from WCS.

A small quantity of material generated during the Prairie Island decommissioning will not be considered suitable for near-surface disposal, and is assumed to be disposed of in a geologic repository, in a manner similar to that envisioned for spent fuel disposal. Such material, known as Greater-Than-Class-C or GTCC material, is estimated to require eight spent fuel storage canisters (or the equivalent) to dispose of the most radioactive portions of the reactor vessel internals. The volume and weight reported in Tables 5.1 through 5.7 represent the packaged weight and volume of the spent fuel storage canisters.

FIGURE 5.1
RADIOACTIVE WASTE DISPOSITION

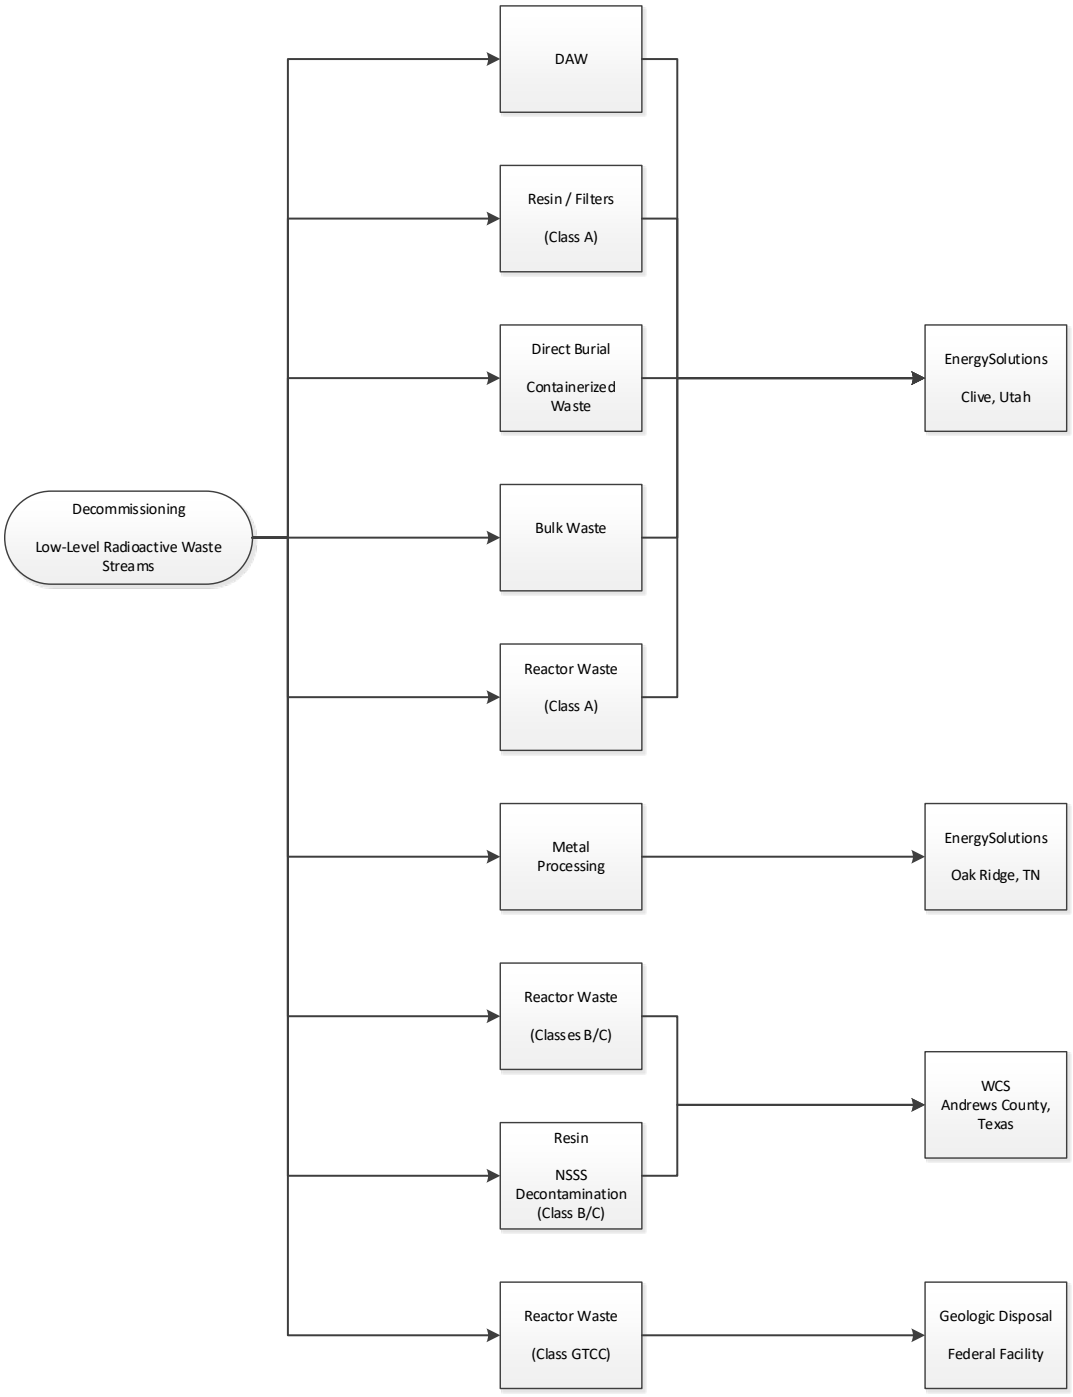

FIGURE 5.2
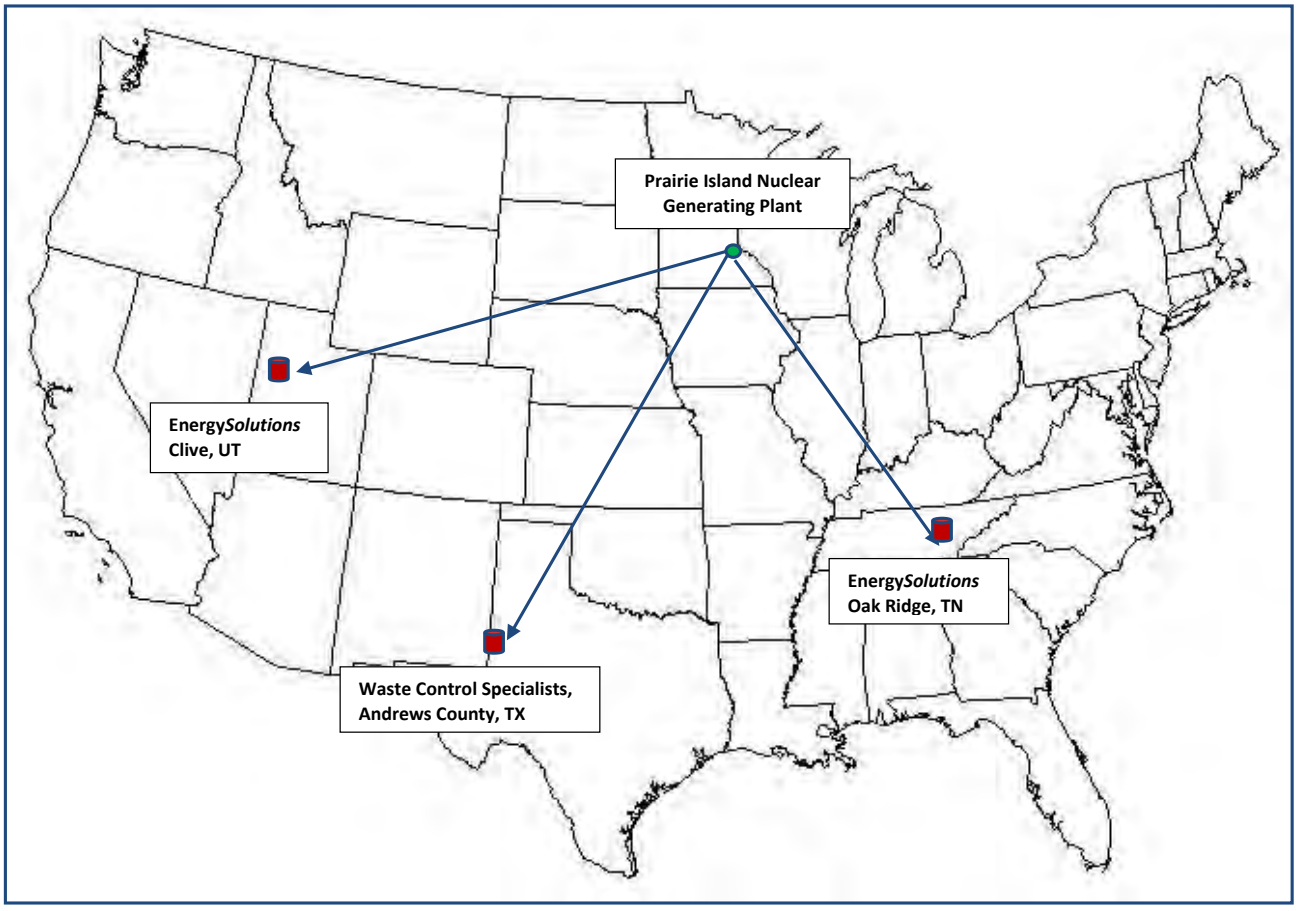
DECOMMISSIONING WASTE DESTINATIONS
RADIOLOGICAL



The figure indicates the destinations for the low-level radioactive waste designated for direct disposal (Clive, Utah) and processing/recovery (Oak Ridge, Tennessee).

Disposition of the Class B and C low-level radioactive waste will be at the Waste Control Specialists site in Andrews County, Texas.

Disposal options (and destinations) for GTCC are still being evaluated.

6. RESULTS

This report presents estimates of the cost to decommission Prairie Island for the selected decommissioning scenarios following the cessation of plant operations. The estimates are based on numerous fundamental assumptions, including regulatory requirements, project contingencies, low-level radioactive waste disposal practices, high-level radioactive waste management options, and site restoration requirements. While not an engineering study, the estimates provide Xcel Energy with sufficient information to assess their financial obligations, as they pertain to the eventual decommissioning of the nuclear station.

The decommissioning scenarios assume continued operation of the station's spent fuel pool for a minimum of five years following the cessation of operations for continued cooling of the assemblies. The existing ISFSI is expanded to accommodate the spent fuel, once sufficiently cooled, until such time that the DOE can complete the transfer of the assemblies to its repository.

Using Scenario 2 as the base case, the cost projected to promptly decommission the station, restore the site, and manage the spent fuel is estimated to be $1.996 billion (2017 dollars). The majority of this cost (approximately 56.8%) is associated with the physical decontamination and dismantling of the nuclear plant so that the operating licenses can be terminated. Another 37.2% is associated with the management, interim storage, and eventual transfer of the spent fuel. The remaining 5.9% is for the demolition of the designated structures and limited restoration of the site.

The primary cost contributors, identified in Tables 6.1 through 6.7, are either labor-related or associated with the management and disposition of the spent fuel or radioactive waste. Program management (including security) is the largest single contributor to the overall cost. The magnitude of the expense is a function of both the size of the organization required to manage the decommissioning, as well as the duration of the program. It is assumed, for purposes of this analysis, that Xcel Energy will hire a contractor to manage the decommissioning labor force. The size and composition of the management organizations varies with the decommissioning phase and associated site activities. However, once the operating licenses are amended or terminated, the staff is substantially reduced for the conventional demolition and restoration of the site, and the long-term care of the spent fuel (for the DECON alternative).

As described in this report, the spent fuel pool will remain operational for a minimum of five years following the cessation of operations. The pool will be isolated and an independent spent fuel island created. This will allow

decommissioning operations to proceed in and around the pool areas. Over the five-year period, the spent fuel will be packaged into transportable canisters for future loading into a DOE-provided transport cask or relocation to the ISFSI (DECON and both SAFSTOR alternatives). The canisters will be stored in horizontal storage casks at the ISFSI until the DOE is able to receive them. Dry storage of the fuel provides additional flexibility in the event the DOE is not able to meet the current timetable for completing the transfer of assemblies to an off-site facility and minimizes the associated caretaking expenses.

The cost for waste disposal includes only those costs associated with the controlled disposition of the low-level radioactive waste generated from decontamination and dismantling activities, including plant equipment and components, structural material, filters, resins and dry-active waste. As described in Section 5, disposition of the majority of the low-level radioactive material requiring controlled disposal is at the Energy*Solutions* facility, with higher-activity waste sent to the WCS facility. Highly activated components, requiring additional isolation from the environment (GTCC), are packaged for geologic disposal. The cost of geologic disposal is based upon a cost equivalent for spent fuel.

A significant portion of the metallic waste is designated for additional processing and treatment at an off-site facility. Processing reduces the volume of material requiring controlled disposal through such techniques and processes as survey and sorting, decontamination, and volume reduction. The material that cannot be unconditionally released is packaged for controlled disposal at one of the currently operating facilities. The cost identified in the summary tables for processing is all-inclusive, incorporating the ultimate disposition of the material.

Removal costs reflect the labor-intensive nature of the decommissioning process, as well as the management controls required to ensure a safe and successful program. Decontamination and packaging costs also have a large labor component that is based upon prevailing wages. Non-radiological demolition is a natural extension of the decommissioning process. The methods employed in decontamination and dismantling are generally destructive and indiscriminate in inflicting collateral damage. With a work force mobilized to support decommissioning operations, non-radiological demolition can be an integrated activity and a logical expansion of the work being performed in the process of terminating the operating licenses.

The reported cost for transport includes the tariffs and surcharges associated with moving large components and/or overweight shielded casks overland, as well as the general expense, e.g., labor and fuel, of transporting material to the destinations identified in this report. For purposes of this analysis, material is moved overland by truck.

Decontamination is used to reduce the plant's radiation fields and minimize worker exposure. Slightly contaminated material or material located within a contaminated area is sent to an off-site processing center, i.e., this analysis does not assume that contaminated plant components and equipment can be decontaminated for uncontrolled release in-situ. Centralized processing centers have proven to be a more economical means of handling the large volumes of material produced in the dismantling of a nuclear plant.

License termination survey costs are associated with the labor intensive and complex activity of verifying that contamination has been removed from the site to the levels specified by the regulating agency. This process involves a systematic survey of all remaining plant surface areas and surrounding environs, sampling, isotopic analysis, and documentation of the findings. The status of any plant components and materials not removed in the decommissioning process will also require confirmation and will add to the expense of surveying the facilities alone.

The remaining costs include allocations for heavy equipment and temporary services, as well as for other expenses such as regulatory fees and the premiums for nuclear insurance. While site operating costs are greatly reduced following the final cessation of plant operations, certain administrative functions do need to be maintained either at a basic functional or regulatory level.

Site Restoration	54,569	68,978	123,547	5.3%
Total [3]	1,205,645	1,143,621	2,349,266	100.0%

[1] Includes engineering

[2] Includes costs for the dry storage system components, spent fuel loading and transfer, spent fuel pool O&M and EP fees, but excludes program management costs (staffing), security and other related costs

[3] Columns may not add due to rounding

TABLE 6.7
SCENARIO 7: SAFSTOR WITH 60 YEAR DFS
DECOMMISSIONING COST ELEMENTS
(thousands of 2017 dollars)

Cost Element	Unit 1	Unit 2	Total	Percentage
Decontamination	7,825	16,452	24,276	1.0%
Removal	108,474	136,691	245,165	9.9%
Packaging	34,003	34,343	68,346	2.8%
Transportation	6,683	7,171	13,854	0.6%
Waste Disposal	53,613	55,347	108,960	4.4%
Off-site Waste Processing	13,846	16,314	30,160	1.2%
Program Management [1]	313,922	284,127	598,049	24.1%
Security	200,143	166,411	366,553	14.8%
Spent Fuel Pool Isolation	13,445	8,963	22,409	0.9%
Spent Fuel Storage (Direct Costs) [2]	138,784	136,422	275,207	11.1%
Insurance and Regulatory Fees	54,180	50,827	105,007	4.2%
Energy	20,134	19,489	39,623	1.6%
Characterization and Licensing Surveys	18,118	20,359	38,478	1.6%
Property Taxes	161,296	156,387	317,682	12.8%
Miscellaneous	17,668	21,945	39,613	1.6%
Railroad Track Maintenance	4,362	4,281	8,644	0.3%
Retention and Severance	28,423	28,423	56,845	2.3%
Security Modifications	5,000	5,000	10,000	0.4%
Prairie Island Indian Community Payments	56,250	55,000	111,250	4.5%
Total [3]	1,256,169	1,223,951	2,480,120	100.0%

Cost Element	Unit 1	Unit 2	Total	Percentage
NRC License Termination	883,602	846,342	1,729,944	69.8%
Spent Fuel Management	317,887	308,520	626,407	25.3%
Site Restoration	54,680	69,089	123,769	5.0%
Total [3]	1,256,169	1,223,951	2,480,120	100.0%

[1] Includes engineering costs

[2] Includes costs for the dry storage system components, spent fuel loading and transfer, spent fuel pool O&M and EP fees, but excludes program management costs (staffing), security and other related costs

[3] Columns may not add due to rounding

APPENDIX A

UNIT COST FACTOR DEVELOPMENT

APPENDIX A
UNIT COST FACTOR DEVELOPMENT

Example: Unit Factor for Removal of Contaminated Heat Exchanger < 3,000 lbs.

1. SCOPE

Heat exchangers weighing < 3,000 lbs. will be removed in one piece using a crane or small hoist. They will be disconnected from the inlet and outlet piping. The heat exchanger will be sent to the waste processing area.

2. CALCULATIONS

Act ID	Activity Description	Activity Duration (minutes)	Critical Duration (minutes)*
a	Remove insulation	60	(b)
b	Mount pipe cutters	60	60
c	Install contamination controls	20	(b)
d	Disconnect inlet and outlet lines	60	60
e	Cap openings	20	(d)
f	Rig for removal	30	30
g	Unbolt from mounts	30	30
h	Remove contamination controls	15	15
i	Remove, wrap, send to waste processing area	60	60
	Totals (Activity/Critical)	355	255

Duration adjustment(s):	
+ Respiratory protection adjustment (50 of critical duration)	128
+ Radiation/ALARA adjustment (37.1 of critical duration)	95
Adjusted work duration	478
+ Protective clothing adjustment (30 of adjusted duration)	143
Productive work duration	621
+ Work break adjustment (8.33 of productive duration)	52
Total work duration (minutes)	673

***** Total duration = 11.217 hr *****

* alpha designators indicate activities that can be performed in parallel

APPENDIX A
(continued)

3. LABOR REQUIRED

Crew	Number	Duration (hours)	Rate ($/hr)	Cost
Laborers	3.00	11.217	$52.61	$1,770.38
Craftsmen	2.00	11.217	$68.16	$1,529.10
Foreman	1.00	11.217	$71.37	$800.56
General Foreman	0.25	11.217	$73.67	$206.59
Fire Watch	0.05	11.217	$52.61	$29.61
Health Physics Technician	1.00	11.217	$76.50	$858.10
Total Labor Cost				$5,194.24

4. EQUIPMENT & CONSUMABLES COSTS

Equipment Costs none

Consumables/Materials Costs

- Universal Sorbent 50 @ $0.61 sq ft {1} $30.50
- Tarpaulins (oil resistant/fire retardant) 50 @ $0.46/sq ft {2} $23.00
- Gas torch consumables 1 @ $20.45/hr x 1 hr {3} $20.45

Subtotal cost of equipment and materials $73.95
Overhead & profit on equipment and materials @ 16.88% $12.48

Total costs, equipment & material $86.43

TOTAL COST:

Removal of contaminated heat exchanger <3000 pounds: $5,280.67

Total labor cost: $5,194.24
Total equipment/material costs: $86.43
Total craft labor man-hours required per unit: 81.88

5. NOTES AND REFERENCES

- Work difficulty factors were developed in conjunction with the Atomic Industrial Forum's (now NEI) program to standardize nuclear decommissioning cost estimates and are delineated in Volume 1, Chapter 5 of the "Guidelines for Producing Commercial Nuclear Power Plant Decommissioning Cost Estimates," AIF/NESP-036, May 1986.

- References for equipment & consumables costs:

    1. www.mcmaster.com online catalog, McMaster Carr Spill Control (7193T88)
    2. R.S. Means (2017) Division 01 56, Section 13.60-0600, page 23
    3. R.S. Means (2017) Division 01 54 33, Section 40-6360, page 718

- Material and consumable costs were adjusted using the regional indices for Minneapolis, Minnesota.

APPENDIX B

UNIT COST FACTOR LISTING
(DECON: Power Block Structures Only)

APPENDIX B

UNIT COST FACTOR LISTING
(Power Block Structures Only)

Unit Cost Factor	Cost/Unit
Removal of clean instrument and sampling tubing, $/linear foot	0.58
Removal of clean pipe 0.25 to 2 inches diameter, $/linear foot	6.16
Removal of clean pipe >2 to 4 inches diameter, $/linear foot	8.78
Removal of clean pipe >4 to 8 inches diameter, $/linear foot	17.10
Removal of clean pipe >8 to 14 inches diameter, $/linear foot	33.02
Removal of clean pipe >14 to 20 inches diameter, $/linear foot	42.99
Removal of clean pipe >20 to 36 inches diameter, $/linear foot	63.24
Removal of clean pipe >36 inches diameter, $/linear foot	75.11
Removal of clean valve >2 to 4 inches	113.25
Removal of clean valve >4 to 8 inches	171.03
Removal of clean valve >8 to 14 inches	330.21
Removal of clean valve >14 to 20 inches	429.92
Removal of clean valve >20 to 36 inches	632.40
Removal of clean valve >36 inches	751.10
Removal of clean pipe hanger for small bore piping	39.61
Removal of clean pipe hanger for large bore piping	140.05
Removal of clean pump, <300 pound	289.85
Removal of clean pump, 300-1000 pound	801.33
Removal of clean pump, 1000-10,000 pound	3,160.77
Removal of clean pump, >10,000 pound	6,117.66
Removal of clean pump motor, 300-1000 pound	334.27
Removal of clean pump motor, 1000-10,000 pound	1,312.24
Removal of clean pump motor, >10,000 pound	2,952.53
Removal of clean heat exchanger <3000 pound	1,698.90
Removal of clean heat exchanger >3000 pound	4,283.30
Removal of clean feedwater heater/deaerator	12,062.93
Removal of clean moisture separator/reheater	24,783.03
Removal of clean tank, <300 gallons	372.70
Removal of clean tank, 300-3000 gallon	1,172.60
Removal of clean tank, >3000 gallons, $/square foot surface area	9.85

APPENDIX B

UNIT COST FACTOR LISTING
(Power Block Structures Only)

Unit Cost Factor	Cost/Unit
Removal of clean electrical equipment, <300 pound	156.50
Removal of clean electrical equipment, 300-1000 pound	544.23
Removal of clean electrical equipment, 1000-10,000 pound	1,088.45
Removal of clean electrical equipment, >10,000 pound	2,584.37
Removal of clean electrical transformer < 30 tons	1,794.81
Removal of clean electrical transformer > 30 tons	5,168.70
Removal of clean standby diesel generator, <100 kW	1,833.23
Removal of clean standby diesel generator, 100 kW to 1 MW	4,091.90
Removal of clean standby diesel generator, >1 MW	8,471.05
Removal of clean electrical cable tray, $/linear foot	14.76
Removal of clean electrical conduit, $/linear foot	6.45
Removal of clean mechanical equipment, <300 pound	156.50
Removal of clean mechanical equipment, 300-1000 pound	544.23
Removal of clean mechanical equipment, 1000-10,000 pound	1,088.45
Removal of clean mechanical equipment, >10,000 pound	2,584.37
Removal of clean HVAC equipment, <300 pound	189.24
Removal of clean HVAC equipment, 300-1000 pound	653.93
Removal of clean HVAC equipment, 1000-10,000 pound	1,303.28
Removal of clean HVAC equipment, >10,000 pound	2,584.37
Removal of clean HVAC ductwork, $/pound	0.61
Removal of contaminated instrument and sampling tubing, $/linear foot	1.95
Removal of contaminated pipe 0.25 to 2 inches diameter, $/linear foot	26.56
Removal of contaminated pipe >2 to 4 inches diameter, $/linear foot	45.20
Removal of contaminated pipe >4 to 8 inches diameter, $/linear foot	72.68
Removal of contaminated pipe >8 to 14 inches diameter, $/linear foot	141.06
Removal of contaminated pipe >14 to 20 inches diameter, $/linear foot	169.46
Removal of contaminated pipe >20 to 36 inches diameter, $/linear foot	234.41
Removal of contaminated pipe >36 inches diameter, $/linear foot	276.97
Removal of contaminated valve >2 to 4 inches	553.32
Removal of contaminated valve >4 to 8 inches	662.47

APPENDIX B

UNIT COST FACTOR LISTING
(Power Block Structures Only)

Unit Cost Factor	Cost/Unit
Removal of contaminated valve >8 to 14 inches	1,348.03
Removal of contaminated valve >14 to 20 inches	1,713.56
Removal of contaminated valve >20 to 36 inches	2,281.53
Removal of contaminated valve >36 inches	2,707.15
Removal of contaminated pipe hanger for small bore piping	184.64
Removal of contaminated pipe hanger for large bore piping	596.64
Removal of contaminated pump, <300 pound	1,182.71
Removal of contaminated pump, 300-1000 pound	2,706.17
Removal of contaminated pump, 1000-10,000 pound	8,653.74
Removal of contaminated pump, >10,000 pound	21,079.34
Removal of contaminated pump motor, 300-1000 pound	1,153.25
Removal of contaminated pump motor, 1000-10,000 pound	3,525.11
Removal of contaminated pump motor, >10,000 pound	7,914.39
Removal of contaminated heat exchanger <3000 pound	5,280.67
Removal of contaminated heat exchanger >3000 pound	15,319.98
Removal of contaminated tank, <300 gallons	1,966.05
Removal of contaminated tank, >300 gallons, $/square foot	37.92
Removal of contaminated electrical equipment, <300 pound	917.52
Removal of contaminated electrical equipment, 300-1000 pound	2,207.05
Removal of contaminated electrical equipment, 1000-10,000 pound	4,251.16
Removal of contaminated electrical equipment, >10,000 pound	8,289.57
Removal of contaminated electrical cable tray, $/linear foot	44.36
Removal of contaminated electrical conduit, $/linear foot	21.71
Removal of contaminated mechanical equipment, <300 pound	1,020.69
Removal of contaminated mechanical equipment, 300-1000 pound	2,437.14
Removal of contaminated mechanical equipment, 1000-10,000 pound	4,686.67
Removal of contaminated mechanical equipment, >10,000 pound	8,289.57
Removal of contaminated HVAC equipment, <300 pound	1,020.69
Removal of contaminated HVAC equipment, 300-1000 pound	2,437.14
Removal of contaminated HVAC equipment, 1000-10,000 pound	4,686.67

APPENDIX B

UNIT COST FACTOR LISTING
(Power Block Structures Only)

Unit Cost Factor	Cost/Unit
Removal of contaminated HVAC equipment, >10,000 pound	8,289.57
Removal of contaminated HVAC ductwork, $/pound	2.66
Removal/plasma arc cut of contaminated thin metal components, $/linear in.	4.78
Additional decontamination of surface by washing, $/square foot	9.88
Additional decontamination of surfaces by hydrolasing, $/square foot	42.77
Decontamination rig hook up and flush, $/ 250-foot length	8,602.39
Chemical flush of components/systems, $/gallon	20.62
Removal of clean standard reinforced concrete, $/cubic yard	76.22
Removal of grade slab concrete, $/cubic yard	86.70
Removal of clean concrete floors, $/cubic yard	424.96
Removal of sections of clean concrete floors, $/cubic yard	1,277.24
Removal of clean heavily rein concrete w/#9 rebar, $/cubic yard	110.08
Removal of contaminated heavily rein concrete w/#9 rebar, $/cubic yard	2,525.79
Removal of clean heavily rein concrete w/#18 rebar, $/cubic yard	149.21
Removal of contaminated heavily rein concrete w/#18 rebar, $/cubic yard	3,340.90
Removal heavily rein concrete w/#18 rebar & steel embedments, $/cubic yard	518.41
Removal of below-grade suspended floors, $/cubic yard	209.25
Removal of clean monolithic concrete structures, $/cubic yard	1,049.70
Removal of contaminated monolithic concrete structures, $/cubic yard	2,512.62
Removal of clean foundation concrete, $/cubic yard	825.21
Removal of contaminated foundation concrete, $/cubic yard	2,340.94
Explosive demolition of bulk concrete, $/cubic yard	56.10
Removal of clean hollow masonry block wall, $/cubic yard	26.77
Removal of contaminated hollow masonry block wall, $/cubic yard	71.77
Removal of clean solid masonry block wall, $/cubic yard	26.77
Removal of contaminated solid masonry block wall, $/cubic yard	71.77
Backfill of below-grade voids, $/cubic yard	32.20
Removal of subterranean tunnels/voids, $/linear foot	131.51
Placement of concrete for below-grade voids, $/cubic yard	150.52
Excavation of clean material, $/cubic yard	3.35

APPENDIX B

UNIT COST FACTOR LISTING
(Power Block Structures Only)

Unit Cost Factor	Cost/Unit
Excavation of contaminated material, $/cubic yard	48.54
Removal of clean concrete rubble (tipping fee included), $/cubic yard	27.60
Removal of contaminated concrete rubble, $/cubic yard	30.99
Removal of building by volume, $/cubic foot	0.35
Removal of clean building metal siding, $/square foot	1.58
Removal of contaminated building metal siding, $/square foot	5.71
Removal of standard asphalt roofing, $/square foot	2.70
Removal of transite panels, $/square foot	2.45
Scarifying contaminated concrete surfaces (drill & spall), $/square foot	14.89
Scabbling contaminated concrete floors, $/square foot	9.21
Scabbling contaminated concrete walls, $/square foot	24.59
Scabbling contaminated ceilings, $/square foot	84.63
Scabbling structural steel, $/square foot	7.64
Removal of clean overhead crane/monorail < 10 ton capacity	759.93
Removal of contaminated overhead crane/monorail < 10 ton capacity	2,265.36
Removal of clean overhead crane/monorail >10-50 ton capacity	1,823.83
Removal of contaminated overhead crane/monorail >10-50 ton capacity	5,435.94
Removal of polar crane > 50 ton capacity	7,608.99
Removal of gantry crane > 50 ton capacity	32,304.44
Removal of structural steel, $/pound	0.23
Removal of clean steel floor grating, $/square foot	5.53
Removal of contaminated steel floor grating, $/square foot	16.69
Removal of clean free-standing steel liner, $/square foot	14.77
Removal of contaminated free-standing steel liner, $/square foot	44.38
Removal of clean concrete-anchored steel liner, $/square foot	7.39
Removal of contaminated concrete-anchored steel liner, $/square foot	51.73
Placement of scaffolding in clean areas, $/square foot	17.11
Placement of scaffolding in contaminated areas, $/square foot	30.30
Landscaping with topsoil, $/acre	24,605.57
Cost of CPC B-88 LSA box & preparation for use	2,083.43

APPENDIX B

UNIT COST FACTOR LISTING
(Power Block Structures Only)

Unit Cost Factor	Cost/Unit
Cost of CPC B-25 LSA box & preparation for use	1,963.90
Cost of CPC B-12V 12-gauge LSA box & preparation for use	1,565.90
Cost of CPC B-144 LSA box & preparation for use	10,460.39
Cost of LSA drum & preparation for use	230.20
Cost of cask liner for CNSI 8 120A cask (resins)	12,394.60
Cost of cask liner for CNSI 8 120A cask (filters)	8,981.65
Decontamination of surfaces with vacuuming, $/square foot	0.93

TOTAL COST TO DECOMMISSION WITH 16.73% CONTINGENCY:	**$897,520**	**thousands of 2017 dollars**
TOTAL NRC LICENSE TERMINATION COST IS 63.73% OR:	**$571,980**	**thousands of 2017 dollars**
SPENT FUEL MANAGEMENT COST IS 30.58% OR:	**$274,479**	**thousands of 2017 dollars**
NON-NUCLEAR DEMOLITION COST IS 5.69% OR:	**$51,061**	**thousands of 2017 dollars**
TOTAL LOW-LEVEL RADIOACTIVE WASTE VOLUME BURIED (EXCLUDING GTCC):	**140,089**	**cubic feet**
TOTAL GREATER THAN CLASS C RADWASTE VOLUME GENERATED:	**3,746**	**cubic feet**
TOTAL SCRAP METAL REMOVED:	**32,925**	**tons**
TOTAL CRAFT LABOR REQUIREMENTS:	**739,753**	**man-hours**

End Notes:
n/a - indicates that this activity not charged as decommissioning expense
a - indicates that this activity performed by decommissioning staff
0 - indicates that this value is less than 0.5 but is non-zero
A cell containing " - " indicates a zero value

TOTAL COST TO DECOMMISSION WITH 14.1% CONTINGENCY:	**$2,979,847**	**thousands of 2017 dollars**
TOTAL NRC LICENSE TERMINATION COST IS 18.73% OR:	**$558,112**	**thousands of 2017 dollars**
SPENT FUEL MANAGEMENT COST IS 79.04% OR:	**$2,355,208**	**thousands of 2017 dollars**
NON-NUCLEAR DEMOLITION COST IS 2.23% OR:	**$66,527**	**thousands of 2017 dollars**
TOTAL LOW-LEVEL RADIOACTIVE WASTE VOLUME BURIED (EXCLUDING GTCC):	**149,906**	**cubic feet**
TOTAL GREATER THAN CLASS C RADWASTE VOLUME GENERATED	**3,746**	**cubic feet**
TOTAL SCRAP METAL REMOVED:	**41,515**	**tons**
TOTAL CRAFT LABOR REQUIREMENTS:	**1,027,670**	**man-hours**

End Notes:
n/a - indicates that this activity not charged as decommissioning expense
a - indicates that this activity performed by decommissioning staff
0 - indicates that this value is less than 0.5 but is non-zero
A cell containing " - " indicates a zero value

APPENDIX G

DETAILED COST ANALYSIS

SCENARIO 5: DECON with 60 Year DFS with Recasking

TOTAL COST TO DECOMMISSION WITH 15.96% CONTINGENCY:	**$1,143,621**	**thousands of 2017 dollars**
TOTAL NRC LICENSE TERMINATION COST IS 73.55% OR:	**$841,160**	**thousands of 2017 dollars**
SPENT FUEL MANAGEMENT COST IS 20.42% OR:	**$233,483**	**thousands of 2017 dollars**
NON-NUCLEAR DEMOLITION COST IS 6.03% OR:	**$68,978**	**thousands of 2017 dollars**
TOTAL LOW-LEVEL RADIOACTIVE WASTE VOLUME BURIED (EXCLUDING GTCC):	**127,986**	**cubic feet**
TOTAL GREATER THAN CLASS C RADWASTE VOLUME GENERATED:	**3,746**	**cubic feet**
TOTAL SCRAP METAL REMOVED:	**41,593**	**tons**
TOTAL CRAFT LABOR REQUIREMENTS:	**980,098**	**man-hours**

End Notes:
n/a - indicates that this activity not charged as decommissioning expense
a - indicates that this activity performed by decommissioning staff
0 - indicates that this value is less than 0.5 but is non-zero
A cell containing " - " indicates a zero value

APPENDIX N10 – NUCLEAR WORKER TRANSITION PLAN

I. INTRODUCTION

Minn. Stat. § 3.8851, subd. 4 requires Northern States Power Company, doing business as Xcel Energy, to submit to the Minnesota Public Utilities Commission updates periodically, with the resource plan filing, of the Worker Transition Plan (WTP) required under Minn. Stat. § 116C.772, subd. 3. The WTP is required to address the event of a shutdown of Prairie Island nuclear generating plant for longer than six months.

The 1995 WTP (the original filing of this plan) reported that the conditions that could lead to a short lead-time reactive worker transition due to an unplanned immediate shutdown were not typical of the scenario facing Minnesota. Minnesota's Monticello and Prairie Island Nuclear generating plants have a long history of being well-maintained resulting in safe, reliable and economic operations. The WTP described in 1995 assumed a long lead-time, proactive approach. Monticello and Prairie Island Units 1 and 2 continue to have strong operating records and are expected to operate until at least 2030, 2033 and 2034 respectively. This update continues to assume the long lead-time proactive approach to a WTP.

II. TRANSITION PLAN PHILOSOPHY

Monticello will reach the end of its current operating license in 11 years, or 2030. As part of our preferred plan, we are proposing to extend Monticello operations through 2040 or 21 years from now. Prairie Island Unit 1 will reach the end of its current operating license in 14 years, or 2033, and Prairie Island Unit 2 will reach the end of its current operating license in 15 years, or 2034. These extended operating periods and Xcel Energy's commitment to employees affords the opportunity to plan for employee transition resulting from a planned plant closure. Xcel Energy will continue to base staffing decisions on operational excellence and Nuclear Regulatory Commission (NRC) requirements that may result in changed staff assignments and levels.

Monticello and Prairie Island nuclear generating plants are operated by dedicated nuclear professionals. The extended plant lives, the fact that many workers will reach retirement age well before the extended licenses will expire, and a strong management commitment are critical to the success of the Xcel Energy Worker Transition Plan. This strategy provides employees the opportunity to develop their skills inventories so they are congruent with the changing needs of the company and the marketplace.

The proactive approach to managing human resources produces a workforce that is motivated, cross-functional and flexible. This approach greatly reduces the need for reactive planning.

Should Prairie Island or Monticello close, there are four transition paths available. They are:

1. Stay with Xcel Energy in a similar job/career path.
2. Stay with Xcel Energy in a different job/career path.
3. Retire.
4. Leave Xcel Energy for outside employment opportunities.

The proactive strategy for managing human resources allows employees to prepare for each path, and thus position themselves for a number of potential outcomes. Xcel Energy acknowledges that a proactive transition requires prior planning, total management support, complete understanding and support throughout all levels of the corporation and a comprehensive guiding process.

Xcel Energy values its employees and recognizes that they make the nuclear operations excellent. Xcel Energy has an obligation to help employees plan for the future. The result of effective planning is a partnership that yields strong nuclear operations and satisfied employees. Approximately 1,150 permanent, skilled positions would be eliminated or restructured should Monticello and Prairie Island close. Providing these employees with avenues to enhance their skills prior to plant closing will make the transition to new jobs (inside or outside of Xcel Energy) easier, but not painless. Xcel Energy's objective is to structure and develop its work force to meet the challenges inherent in a competitive business environment. That objective will be accomplished by:

1. Establishing Business Plan workforce effectiveness goals.
2. Translating those goals into an effective Human Asset Plan.
3. Producing employee development plans.

A breakdown of the number of employees that work at Monticello and Prairie Island appears in Table 1 below.

Table 1: Nuclear Employee Breakdown

	Nuclear Department		Total
	Bargaining	Non-bargaining	
Monticello	185	325	510
Prairie Island	335	311	646
Total	520	636	1,156

III. XCEL ENERGY TRANSITION PROCESSES

The transition processes described below apply to both non-bargaining and bargaining unit employees at Monticello and Prairie Island. For bargaining unit employees the transition plan is in accordance with the collective bargaining agreement and Xcel Energy programs and processes as described below.

IV. INTERNAL PLACEMENT

A. Job Opportunity Bulletin

Xcel Energy provides online notification of employment and career development opportunities in all new or replacement positions. This process, in accordance with our collective bargaining agreement, is used prior to outside hiring.

B. Leadership Essentials

Xcel Energy has a program to identify employees interested in becoming a member of the Xcel Energy management team, and provides assessment and development to them. Leadership Essentials is an on-line resource designed to help both beginning and experienced leaders learn, and continue to develop various leadership skills. All union employees are invited to participate.

C. Corporate Training Programs

Xcel Energy offers employees training and development courses for skills needed to stay current in their present job and development courses to prepare them for future positions. This training covers technical, computer and business skills.

D. Apprenticeship Training Programs

An apprentice is a person engaged in training for one of the skill areas covered in the current labor agreement. Programs are State of Minnesota registered and provide on-the-job training and related instruction in all areas of the apprenticeship being served.

E. Tuition Reimbursement

The Tuition Reimbursement Program gives employees financial assistance to take courses offered by accredited schools and institutions of higher learning to complete a degree program.

F. Severance

1. The severance pay agreement for bargaining unit employees is covered in the current labor agreements with IBEW locals 160 and 949.
2. The Company has a severance plan for non-bargaining employees which covers regular, full-time or part-time employees of the Company not covered by a current labor agreement. To be eligible for severance, certain eligibility requirements must be met.

V. SUMMARY

The foundation for this type of worker transition program is based on the availability of long-term planning. If a premature closure of Prairie Island or Monticello were to occur, the results would be less favorable. In that case, employees would be afforded less time to prepare themselves for other employment within Xcel Energy or for careers outside of the company. No amount of prior planning can alleviate employees' personal hardships should a valuable and efficient plant be forced to close prematurely. Such an occurrence would be highly speculative, and it would not be cost-effective to prepare contingencies based on scenarios that are not likely to occur.

VI. CONCLUSIONS

1. Xcel Energy is committed to its employees. That commitment is reflected in the scope of resources available to employees. Xcel Energy will continue to invest heavily in employees' training and development so that the transition to a business environment will be proactive.
2. Xcel Energy's commitment to excellence in operations is unequivocal, as is the Company's commitment to operate Monticello and Prairie Island

Units 1 and 2 until 2030, 2033 and 2034, respectively. In addition, as part of our preferred plan we are proposing to extend Monticello another 10 years through 2040.

3. The long lead-time prior to potential plant closings affords Xcel Energy and its employees an opportunity to plan for the transition.
4. An orderly transition is possible through Business and Human Asset Planning as performed by Xcel Energy.

VII. COMMITMENTS

1. Xcel Energy will continue to account for changes in the workforce through business planning and Human Asset Planning.
2. Xcel Energy will continue to work with affected unions to promote the retention and training of its highly skilled and dedicated workforce.

APPENDIX O1 – SUMMARY OF IRP STAKEHOLDER ENGAGEMENT

Our plans for the future of our integrated system impact five states, millions of customers, thousands of employees, and hundreds of communities. We understand the interest and desire for stakeholders to be involved and help shape the future of our system. In light of this interest, we developed our Integrated Resource Plan through a robust external stakeholder process. This includes holding stakeholder workshops, engaging third party consultants, participating in studies that evaluate the impact of plant retirements on host communities, and working with the labor unions to ensure smooth transitions for our impacted employees. Below we discuss our stakeholder work to date in more detail.

I. STAKEHOLDER WORKSHOPS

The Company made a concerted effort to work with stakeholders in developing the Resource Plan, through both workshops and one-on-one meetings. We sent email invitations to over 300 individual stakeholders or organizations and held 13 public workshops that provided a forum for productive dialogue and education. Our goal was to educate stakeholders on the resource planning process and our Upper Midwest system – as well as gather stakeholder feedback and perspectives for incorporation into our Resource Plan. We also wanted to increase accessibility to our subject matter experts and the supporting data while enhancing collaboration. The meetings also revealed stakeholders' desire for additional, deeper discussions about our system, our Resource Plan, and the broader context of statewide decarbonization pathways.

Our meetings covered a variety of topics and featured external speakers and stakeholders including Chris Clack with Vibrant Clean Energy, Jesse Jenkins with Massachusetts Institute of Technology,[1] MISO, the Center for Energy and Environment, the Coalition of Host Communities, and Community Power. Table 1 below lists the Workshops we hosted.

[1] Now at the Harvard University Center for the Environment.

Table 1: Stakeholder Workshops

Workshop Topic	Date
The Evolving Integrated Planning Process	6/26/19
The Evolving Electric System - Part 1	8/22/18
The Evolving Electric System - Part 2	8/28/18
Economic and Technical Considerations – Part 1	9/10/18
Economic and Technical Considerations – Part 2	9/24/18
Recap 9/10 Workshop Webinar (Economic and Technical Considerations – Part 1)	10/5/18
Preliminary Results – Part 1	10/22/18
Preliminary Results – Part 2	10/23/18
Demand-Side Management, Storage and Q&A Panel	12/14/18
Modeling Inputs & Assumptions Webinar	2/11/19
Host Community Considerations	2/12/19
Xcel Energy Non-Technical Overview Session	4/2/19
E3 Modeling Results	4/17/19
Xcel Energy Preliminary Preferred Plan	5/20/19

We also filed all supporting documents and presentations from the workshops in Docket No. E002/RP-15-21.

As this Resource Plan contemplates the long-term resource mix for five states, as discussed in the Planning Landscape section, we have also had discussions with various regulatory agencies in multiple jurisdictions to hear and understand their needs and concerns and incorporate those where possible.

As a result of all of this stakeholder collaboration, we made changes to several inputs and modeling approaches and also kept this in mind as we prepared the narrative supporting our proposed plan. For instance, in response to input from energy efficiency stakeholders and using the results from the *Minnesota Energy Efficiency Potential Study*,[2] we modeled energy efficiency as a supply side resource for the first time in this Resource Plan, an innovation that led to significantly more energy efficiency being selected than in prior plans. We also changed the source for our renewable pricing assumptions in response to stakeholder feedback. And in response to stakeholders' strong interest in electrification as a possible pathway to accelerate progress on the State's greenhouse gas goals, we created a load forecast sensitivity exploring the potential energy and peak demand impacts on our system of a scenario with aggressive electrification of transportation, water heating and space heating. We

[2] *Minnesota Energy Efficiency Potential Study: 2020–2029*. Conservation Applied Research and Development (CARD) FINAL Report. Prepared for the Minnesota Department of Commerce, Division of Energy Resources, by Center for Energy and Environment, Optimal Energy and Seventhwave. December 2018.

appreciate the time and input stakeholders have provided to date and believe the proposed plan—and this filing— has benefitted from it. We look forward to continued discussions as this process progresses.

II. EXTERNAL CONSULTANTS

We engaged a national expert on energy policy and economics, Dr. Susan Tierney with Analysis Group, to facilitate and host our Resource Plan stakeholder workshops as well as several smaller stakeholder meetings. Dr. Tierney not only brought a national perspective into the conversation but was also an independent third party that helped facilitate engaging and productive dialogue with stakeholders.

We also retained a consultant, Energy and Environmental Economics, Inc. (E3), to perform independent modeling and analysis of our system in order to ensure transparent work and access to the data and models for stakeholders. E3 is a recognized industry-leading firm based in San Francisco and consults extensively with utilities, developers, government agencies, and environmental groups on clean energy issues. E3's experience analyzing the impacts of deep decarbonization on utility systems in other parts of the country was very valuable to us in evaluating the impacts of decarbonizing our Upper Midwest System. E3 used three types of models to provide perspective on our Resource Plan:

- The RESOLVE model, which evaluates and optimizes the least-cost portfolios of resources to meet system demand considering carbon and other constraints,
- The RECAP model, which evaluates the reliability of electric energy and system capacity of the optimized resource portfolios over thousands of simulated weather years, and
- The PATHWAYS model, an economy-wide representation of infrastructure, energy use, and emissions within a specific jurisdiction used to create emissions accounting scenarios and model energy and climate policies. PATHWAYS was used in this project to evaluate scenarios for meeting Minnesota's statutory goal of 80 percent economy-wide reduction in greenhouse gases below 2005 levels by 2050.

E3's independent modeling results, which were generally consistent and supportive of our Strategist modeling results, were presented to, and discussed with, stakeholders in a workshop, and the results were made publicly available via the eDockets filing system after the stakeholder workshops. In addition, their completed RESOLVE and RECAP reports are also included with this Resource Plan submission as Appendix P2.

Working with E3 on their PATHWAYS to model scenarios to achieve Minnesota's 80 percent economy-wide greenhouse gas reduction goal provided a broader context for our Resource Plan, exploring the potential not only to decarbonize the statewide electricity system but also spread the benefit of low-carbon electricity to other economic sectors. E3's PATHWAYS Report is provided as Appendix P3. E3 modeled two mitigation scenarios – High Electrification and High Biofuels – and three sensitivities, as summarized in Appendix F4. Stakeholder feedback, both in the September 23 and October 24, 2018 stakeholder workshops and in individual meetings, informed the assumptions and modeling approach. In addition, the Company and E3 met with the Minnesota Pollution Control Agency (PCA) and Minnesota Department of Transportation (MnDOT) during the modeling process to acquire state-specific emissions, transportation, and econometric data, discuss assumptions and methodology, and present results. We offered to make the PATHWAYS model, now calibrated for Minnesota, available to the State for future analyses supporting the statewide greenhouse gas goals. As an immediate outgrowth of this effort, MnDOT is now working with E3 in the Pathways to Decarbonizing Transportation project, where E3 is using PATHWAYS to model strategies for reducing greenhouse gas emissions from the transportation sector.[3] Analyses for other sectors may follow.

III. HOST COMMUNITY WORK

The Company is participating in a study overseen by the Center for Energy and Environment (CEE) that will examine the impacts of the large baseload generation plants in Minnesota on the host communities. The other participants in the study include the Coalition of Utility Cities, Minnesota Power, and the Prairie Island Indian Community. The study will consist of a quantitative and qualitative component. The quantitative component of the study is similar to the study we conducted for Sherco 1 and 2 in our last IRP. For the qualitative component, CEE will engage with host community residents and business to gauge awareness, opinions and concerns around potential power plant closures. Efforts on both components are underway and we will supplement this IRP filing when each component is completed. As this docket progresses, we expect to be able to incorporate further findings and hold additional discussions incorporating the finalized report outcomes. Further discussion of the scope and status of this study is included as Appendix O2.

In addition, we also worked with the Nuclear Energy Institute (NEI) to evaluate the impact of our nuclear fleet on the Minnesota Economy. Our nuclear plants employ approximately 1,400 staff in and around the Monticello and Redwing communities,

[3] See http://www.dot.state.mn.us/sustainability/pathways.html.

which translates into an estimated 4,200 additional jobs in other industries across Minnesota. The plants are also important sources of tax base for their host communities, resulting in a combined total of approximately $42 million in state and local taxes annually. In total, Xcel Energy's nuclear operations contribute approximately $1 billion in annual economic benefits throughout the state. These and other benefits area summarized in NEI's April 2017 report titled "The Impact of Xcel Energy's Fleet on the Minnesota Economy," which looked at data from 2014-2016[4] and is attached as Appendix O3.

We acknowledge the role our plants play in the communities in which they are located and look forward to working with these stakeholders on transition plans as this Resource Plan progresses and plant closure dates draw nearer.

IV. LABOR

We are also working closely with labor unions and that work has resulted in support from the Infrastructure Union (LIUNA) for our preferred plan. LIUNA has stated that they appreciate and acknowledge that Xcel Energy has provided high-quality jobs that have sustained families and communities for generations and appreciate our commitment to supporting communities and employees through this energy transition.

Moving forward we will continue to work with local unions and set a course to negotiate multiskilling for the plants that are impacted by this Resource Plan. This skill set will position our employees for other job opportunities within Xcel Energy. As we get closer to plant closure dates, temporary work force will be utilized to back-fill impacted employees who have moved to other positions within the Company. This strategy lessens the burden and stress for impacted employees to find positions, as plant near closure dates.

In addition, plant management, Work Force Relations and Human Resources will work together with other business organizations within Xcel Energy to help coordinate interviews for affected employees.

[4] The 1,400 staff and $42 million in state and local taxes referenced above reflects updated information as through 2018.

V. CONCLUSION

We understand the interest and desire for our stakeholders to be involved and help shape the future of our system. We have put forward a concerted effort to engage these stakeholders at the outset and believe we have done a good job at doing so—but this work is just beginning. As this process unfolds and the plant closure dates approach, we will continue our successful track record of engaging parties, transitioning our workforce, looking for new investments, creating new jobs, and working with impacted communities and employees on transition plans.

APPENDIX O2 – SCOPE & OUTLINE: CENTER FOR ENERGY & ENVIRONMENT STUDY

The Company is participating in a study overseen by the Center for Energy and Environment (CEE) that will examine the impacts of the large baseload generation plants in Minnesota on the host communities. The other participants in the study include the Coalition of Utility Cities (CUCs), Minnesota Power, and the Prairie Island Indian Community. The CUCs are a coalition of communities that host large baseload generation plants in Minnesota and include: Becker, Monticello, Red Wing, Oak Park Heights and Cohasset. With the support of the McKnight Foundation, the Just Transition Fund, and the Initiative Foundations of Minnesota, the CUCs contracted with CEE to oversee a study on the direct and indirect financial and social impacts of hosting a baseload power plant on the host communities.

A portion of the host community impact study will be similar to the study conducted for Sherco 1 and 2 in our last Resource Plan. The study will evaluate alternative retirement and replacement scenarios for our remaining baseload facilities. The study will also evaluate the impacts of Minnesota Power's Boswell plant on the Cohasset area. In addition, the study will provide a qualitative component that will include interviews and surveys of key stakeholders in the local area of each plant. The independent oversight of CEE and the direct participation of impacted communities are important components that we believe will lend additional credibility to the study. On February 12, 2019, we hosted a workshop as part of the Resource Plan process on the scope of this study as part of our outreach efforts in advance of our July 1 filing. At that workshop, the CUC presented on issues facing host communities and included individual presentations by representatives from Becker, Oak Park Heights, Red Wing, Monticello, and the Prairie Island Indian Community. The study scope and process was well received by attendees of the workshop.

The study will consist of a quantitative and qualitative component. Efforts on both components are underway and we will supplement this Resource Plan filing when each component is complete. We expect to provide a supplement on the quantitative component within the next 60 days. A report on the qualitative component is expected to be completed in November.

To support the quantitative effort, CEE has contracted with the University of Colorado to conduct economic modeling of the local and statewide impacts of the retirement of the baseload generation plants in Minnesota. The Company retained the University of Colorado to conduct the study for Sherco 1 and 2 in our last IRP. The Business Research Division (BRD) of the Leeds School of Business at the University of Colorado Boulder will analyze the economic impact of alternative plant

retirement scenarios on their respective host communities. The purpose of this part of study is to provide third-party research examining the economic positive and negative effects of different scenarios. The scenarios analyzed will reflect five plant retirement scenarios as summarized below, including our preferred plan.

Scenarios to be Analyzed in the Host Community Impact Study								
Strategist Scenario	**Description**	**Coal Retirements**				**Nuclear**		
		Sherco 1	Sherco 2	Sherco 3	AS King	Monticello	Prairie Island 1	Prairie Island 2
1	**Reference**	2026	2023	2040	2037	2030	2033	2034
2	**Early King**	2026	2023	2040	2028	2030	2033	2034
4	**Early Coal**	2026	2023	2030	2028	2030	2033	2034
9 Pref. Plan	**Early Coal; Extend Monti**	2026	2023	2030	2028	2040	2033	2034
10	**Early King; Extend Monti**	2026	2023	2040	2028	2040	2033	2034
12	**Early Coal; Extend All Nuclear**	2026	2023	2030	2028	2040	2043	2044

This quantitative analysis will examine the baseload retirement scenarios, above, and the added resources based on the resource expansion plans in each scenario, which correspond to scenarios analyzed using the Strategist model. The analysis will consider operating expenditures, capital expenditures, and consumer rate costs for each scenario above relative to the reference scenario.

The research analysis method to be used for this study is the Regional Economic Models, Incorporated's (REMI) input-output, general equilibrium, econometric, and economic geography model, using state and national economic and demographic data, as well as data from the Company including capital expenditures, operating expenditures, and revenue requirements for each scenario. The study will look at near-term, mid-term, and long-term impacts and will capture the economic activity related to decommissioning and the construction of replacement generation.

While the specific location of replacement generation is unknown, a portion of the replacement generation will be assumed to be constructed within Minnesota and the study will examine impacts on the State of Minnesota. The REMI modeling will analyze the economic impacts on each host county and well as the state of Minnesota. The model allows for the analysis of changes in spending, investment, and employment in each region. We will supplement our IRP filing with the report from the BRD as soon as it is available.

The Host Community Impact study will also contain a qualitative component. CEE will collect responses to a questionnaire from community residents to gauge awareness, opinions and concerns around potential power plant closures. CEE will also conduct interviews with community members and leaders in each affected community, key stakeholders representing labor, and other impacted stakeholders. CEE will develop a report that identifies overarching themes and findings including issues that may be unique for specific communities. We will supplement our Resource Plan filing with the qualitative report once it is available.

We are grateful to CEE for overseeing this study and to the study participants for engaging in this constructive exercise. As we move forward with our carbon reduction goals, we are cognizant that phasing out some of our legacy generation has a significant impact not only on our energy mix, but on the economies of communities where those plants are located and the employees who work in those plants. We are dedicated to working with our employees, communities, and stakeholders to manage community impacts throughout our clean energy transition. Our baseload generation plants are prominent places of employment and contributors to the property tax base in the host communities. This is why we make efforts to spur economic development in locations where our current units will eventually be phased out.

For example, since our most recent Resource Plan, where we proposed to retire the Sherco 1 and 2 coal units in Becker, we have worked extensively with the local government, community stakeholders, and the state to draw new development to support the local economy. This includes a planned combined cycle generating unit at the Sherco site, the Northern Metal Recycling facility, and, prospectively a new Google data center with energy matched by a wind facility. Some of that activity (e.g. the Google data center) is also anticipated to spur new renewable energy development on our system.

In addition to the community impacts, we are also aware that these plant closures impact our employees and their families. With this in mind, and consistent with our past practices, we will work with these impacted employees to transition them to other Xcel Energy plants or areas of the company. In the past, when plants have been closed or converted (and impacted headcount) we have provided résumé writing services, support for interview practice, job training, and job shadowing opportunities. Through natural attrition and job re-locations, we have been able to successfully "re-home" nearly all impacted employees from plant closures and conversions to date.

As we continue toward achievement of our aggressive carbon goals, we will continue to make significant investments in clean energy in the states we serve. As we do so, we will look for opportunities to create fair access to clean energy programs, jobs and economic development opportunities. The Host Community Impact study will provide further context and opportunities for engagement with our communities, employees, and stakeholder as we continue to work together on the clean energy transition.

The Impact of Xcel Energy's Nuclear Fleet on the Minnesota Economy

Executive Summary

Xcel Energy Inc. (Xcel Energy) owns and operates two nuclear energy facilities, including three reactors, in Minnesota and has its headquarters in Minneapolis, Minnesota. The two nuclear energy facilities are:

- Monticello Nuclear Generating Plant in Monticello, Minnesota
- Prairie Island Nuclear Generating Plant in Red Wing, Minnesota

Almost 6,100 jobs in Minnesota result from Xcel Energy's nuclear operations.

The two nuclear facilities have been an integral part of the region's clean energy portfolio and economic fabric since the 1970s. They have generated reliable emission-free electricity, thousands of jobs, and billions of dollars of economic activity while Xcel Energy has been deeply involved in its local communities, proving the plants' value as economic contributors to Minnesota and the Upper Midwest.

To quantify the employment and economic impact of these facilities, the Nuclear Energy Institute (NEI) conducted an independent analysis. Based on data provided by Xcel Energy on employment, operating expenditures, revenues and tax payments, NEI conducted the analysis using a nationally recognized model to estimate the facilities' economic impacts on the Minnesota economy. Regional Economic Models, Inc. (REMI) developed the Policy Insight Plus (PI+) economic impact modeling system, the methodology employed in this analysis. (See section 5 of this report for more information on the REMI methodology.)

Key Findings

Xcel Energy's nuclear operations support:

Xcel Energy's nuclear operations are estimated to generate $1 billion of total economic output annually in Minnesota.

Economic stimulus. Xcel Energy's nuclear operations are estimated to generate $1 billion of total economic output annually, which contributes $600 million to Minnesota's gross state product each year. This study finds that for every dollar of output from Xcel Energy's nuclear operations, the state economy produces $1.98.

Tax impacts. NEI estimates that Xcel Energy's nuclear facilities in Minnesota contribute about $33 million in state and local taxes annually. In 2015, Xcel Energy reported over $34.5 million in state and local taxes paid. Xcel Energy is the largest property tax payer in Minnesota. NEI estimates that Xcel Energy's nuclear facilities contribute over $113 million in federal taxes each year.

Thousands of high-skilled jobs. Approximately 1,700 jobs exist at Xcel Energy's nuclear energy facilities, which includes 140 nuclear support positions at its headquarters in Minneapolis. This direct employment creates about 4,200 additional jobs in other industries in Minnesota. A total of

nearly 6,100 jobs in Minnesota are a result of Xcel Energy's nuclear operations.

Xcel Energy's nuclear operations result in a total tax impact of approximately $146 million to the local, state and federal governments each year.

Clean electricity for Minnesota. Xcel Energy's nuclear facilities generate about 21 percent of Minnesota's electricity and about 54 percent of the state's carbon-free electricity. Without the carbon-free electricity produced by these nuclear plants, an estimated 12 million metric tons of carbon dioxide would be released annually, the equivalent of putting more than 2.6 million additional cars on Minnesota's roadways each year, or double the number of passenger cars in all of Minnesota. By 2030, these nuclear plants will have provided almost $9 billion in avoided emissions benefits.

Reliability leaders. During full-power operations, the three reactors provide 1,770 megawatts of around-the-clock electricity for Minnesota homes and businesses. Over the last 10 years, the facilities have operated at approximately 85 percent of capacity, which is significantly higher than all other forms of electric generation. This reliable production helps offset potential price volatility of other energy sources (e.g., natural gas) and the intermittency of renewable electricity sources. Nuclear energy provides reliable electricity to businesses and consumers and helps prevent power disruptions which could lead to lost economic output, higher business costs, potential loss of jobs, and losses to consumers.

Without the carbon-free electricity produced by these nuclear plants, an additional 12 million metric tons of carbon dioxide would be released annually, the equivalent of the emissions from over 2 million cars each year.

Community and environmental leadership. Xcel Energy is a corporate leader in its neighboring communities, supporting education initiatives, environmental and conservation projects, and numerous charitable organizations.

Section 1
Background and Generation History

Monticello Nuclear Generating Plant

Dates of commercial operation
1971

Location
40 miles northwest of the Twin Cities

License Expiration Year
2030

Reactor Type
Boiling water

Total Electrical Capacity (Megawatts)
671

Prairie Island Nuclear Generating Plant

Dates of commercial operation
Prairie Island 1 - 1973
Prairie Island 2 - 1974

Location
40 Miles southeast of the Twin Cities

License Expiration Years
Prairie Island 1 - 2033
Prairie Island 2 - 2034

Reactor Type
Pressurized water

Total Electrical Capacity (Megawatts)
Prairie Island 1 - 550
Prairie Island 2 - 550

The Monticello Nuclear Generating Plant (Monticello) is located on 215-acre site in Monticello, Minnesota. It consists of a single, Boiling Water Reactor (BWR) that produces 671 MW of non-emitting baseload power.

The Prairie Island Nuclear Generating Plant (Prairie Island) is located on a 575-acre site in Red Wing, Minnesota. It consists of two Pressurized Water Reactors (PWRs) that together produce 1,100 MW of non-emitting base-load power.

Reliable Electricity Generation

Over the past decade, the three reactors operated at an average capacity factor of 85 percent. Capacity factor, a measure of electricity production availability, is the ratio of actual electricity generated to the maximum possible electric generation during the year.

Xcel Energy's nuclear plants typically generate nearly over 13 million megawatt-hours of electricity ever year. In 2015, Xcel Energy's reactors generated over 20 percent of the electricity in Minnesota. The three reactors provide enough electricity for approximately 1.4 million Minnesota households (if all of the electricity went to the residential sector).

Monticello and Prairie Island operate in the Midcontinent Independent System Operator (MISO) region, which stretches from Louisiana to Canada which covers portions of 15 states and Manitoba. Along with 14 other nuclear reactors in that operate in MISO, nuclear power keeps wholesale prices 9 percent lower in MISO than they would be without nuclear power.[1]

Thousands of High-Skilled, Well-Paying Local Jobs

Xcel Energy's nuclear operations employ nearly 1,600 full-time workers at the plants, and 140 support and executive positions at its Minneapolis headquarters. This employment supports an additional 4,200 jobs in other economic sectors in Minnesota. In total, these plants support 6,100 jobs across Minnesota (including those at the plant). The annual payroll for the direct jobs is approximately $240 million. Most jobs at nuclear power plants require technical training and are typically among the highest-paying jobs in the area. Nationwide, nuclear energy jobs pay 36 percent more than average salaries in a plant's local area according to an NEI analysis.[2]

[1] *The Nuclear Industry's Contribution to the U.S. Economy*, The Brattle Group, July 2015.

[2] *NEI Factsheet: Job Creation and Economic Benefits of Nuclear Energy*.

Safe and Clean for the Environment

Nuclear facilities generate large amounts of electricity without emitting greenhouse gases or other air pollutants. State and federal policymakers recognize nuclear energy as an essential source of safe, reliable electricity that meets both our environmental needs and the state's demand for electricity.

In 2015, the operation of these three reactors prevented the emission of 12 million metric tons of carbon dioxide,[3] about the same amount emitted by over 2 million cars each year. Overall, Minnesota's electric sector emits more than 32 million metric tons of carbon dioxide annually. The three reactors also prevent the emission of more than 11,100 tons of nitrogen oxide, equivalent to that released by 1.2 million cars, and 16,800 tons of sulfur dioxide. Sulfur dioxide and nitrogen oxide are precursors to acid rain and urban smog.

[3] Emissions prevented are calculated using regional fossil fuel emission rates from the U.S. Environmental Protection Agency and plant generation data from the U.S. Energy Information Administration.

Section 2

Economic Benefits in Minnesota

NEI used the REMI PI+ model to analyze economic and expenditure data provided by the plants to develop estimates of their economic benefits (more information on REMI can be found in Section 5).

The economic impacts of the Monticello and Prairie Island plants and the nuclear operations at Xcel Energy headquarters consist of direct and secondary impacts. The main variables used to analyze these impacts are:

Output
The direct output is the value of power produced by the Xcel Energy facilities. In the case of Xcel Energy's headquarters, it is the value of the nuclear support operations. The secondary output is the additional economic activity created as a consequence of the electricity generation. The direct output will impact the economic activity in other industries and how those employed at the facilities influence the demand for goods and services within the community.

Employment
The direct employment is the number of jobs at the Xcel Energy facilities. Secondary employment is the number of jobs in the other industries supported as a result of Xcel Energy's operations.

Gross State Product
Gross state product is the value of goods and services produced by labor and property at the Xcel Energy facilities—e.g., sales (i.e., output) minus intermediate goods. In the REMI model, operations is the final good from an Xcel Energy nuclear plant. Intermediate goods are the components purchased to make that electricity due to projected increases in electricity prices.

Xcel Energy's nuclear facilities are predicted to provide nearly $16 billion in economic benefits and $3.5 billion in disposable personal income benefits over the next 15 years.

Disposable Personal Income
Disposable personal income is the total after-tax income that residents in the analyzed region would receive. This value is available for purchases on groceries and clothing or for saving and investing for the future in things like college education, retirement or a mortgage.

Substantial Economic Drivers

The direct output in 2016 of the Xcel Energy nuclear facilities were estimated to total $531 million (the value of the electricity produced at the plants), with a total economic output on the state of $1.05 billion. In other words, for every dollar of output, the state economy produced $1.98. By 2030, the total economic output is estimated to increase to $1.11 billion.

In 2016, Xcel Energy's nuclear facilities were estimated to contribute $595 million to Minnesota's gross state product (GSP) and, by 2030, the GSP stays constant at almost $600 million.

Figure 2.0
Xcel Energy Nuclear Operations' Total Output and Gross State Product Contributions to Minnesota
*(dollars in 2015 billions)**

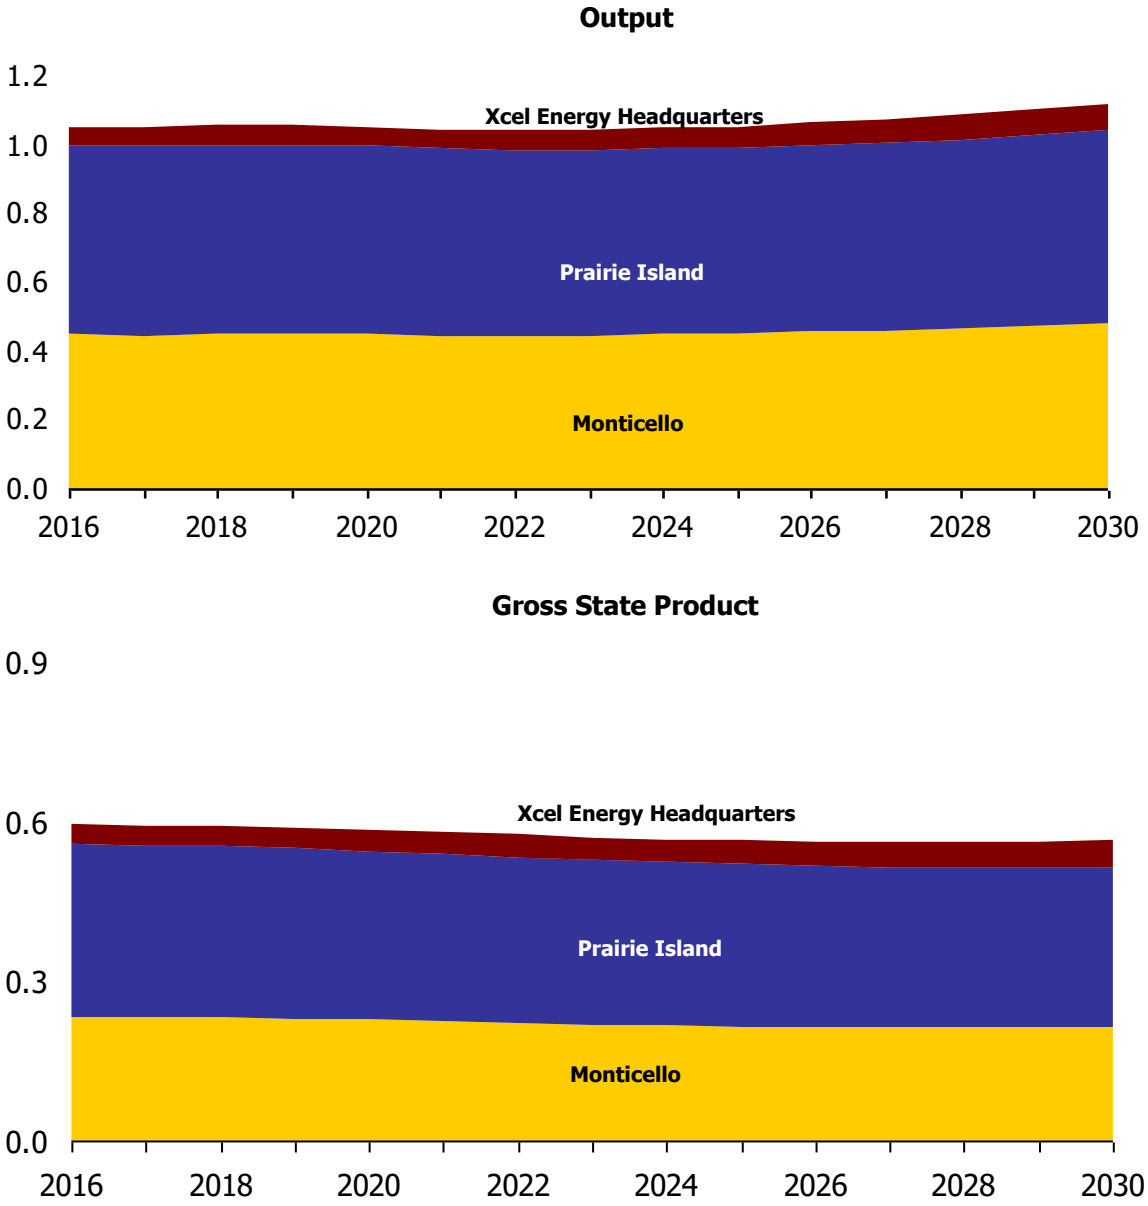

Figure 2.0 shows the value of total output and contributions to GSP from the operation of Xcel Energy's nuclear facilities through 2030, using spending data provided by Xcel Energy.

The three reactors' largest impacts are on the utilities sector, while the headquarters' greatest impact is on the corporate management sector. Xcel Energy's facilities have a substantial impact on the professional, scientific, and technical services sector—because of the volume of specialized services required to operate and maintain a nuclear power plant. Finally, there are beneficial impacts in Minnesota on the manufacturing and administrative and waste management sectors. Other sectors that benefit from the facilities' operations in Minnesota include finance and insurance, health care, retail trade, and real estate.
A full depiction of the sectors in Minnesota that benefit from the facilities is in Table 2.0.

Table 2.0
Estimated Total Output of Xcel Nuclear Operations on Minnesota's Economic Sectors in 2016 *(in millions of 2015 dollars)*

Sector Description	Monticello	Prairie Island	Xcel Energy HQ	Total

Total	**447**	**550**	**54**	**1,051**

Job Diversity and Creation

Xcel Energy's nuclear business activities stimulate the state's labor income and employment. Over 1,600 people work at Xcel Energy's nuclear plants and 140 more are employed at its Minneapolis headquarters for nuclear operations. These jobs stimulate another 4,200 jobs in other sectors in the state. All told, Xcel Energy's operations support nearly 6,100 jobs in Minnesota.

Table 2.1
Xcel Energy's Estimated Support in Direct and Secondary Jobs in Minnesota in 2016

Occupation	Monticello	Prairie Island	Xcel Energy HQ	Total
Utilities	807	870	1	1,678
Administrative and Waste Management Services	474	479	14	967
Professional, Scientific, and Technical Services	396	400	24	820
Other Services, except Public Administration	351	365	21	737
Retail Trade	159	185	33	377
Health Care and Social Assistance	133	154	25	312
Finance and Insurance	80	87	18	185
Management of Companies and Enterprises	16	17	147	180
Manufacturing	85	87	4	176

Transportation and Warehousing	28	30	4	62
Real Estate and Rental and Leasing	23	25	6	54
All Other Industries	31	37	9	77
Total	**2,777**	**2,946**	**338**	**6,061**

As discussed earlier in Section 2, the types of jobs supported by Xcel Energy's nuclear operations are diverse. Jobs supported range from office jobs in the professional, scientific, and technical services, finance and insurance, and public administration jobs to blue-collar jobs in construction and manufacturing to life-saving jobs in healthcare.

Table 2.1 details the numbers and types of jobs that Xcel Energy are supported in 2016. Xcel Energy's workers are included in the occupation categories in the table.

Economic Stimulus Through Taxes

Xcel Energy's nuclear operations resulted in an estimated annual total tax impact of $146 million to the local, state and federal governments. This includes the direct impact and secondary impacts, because plant expenditures increase economic activity, leading to additional income and value creation and, therefore, to additional tax revenue from other sectors.

Xcel Energy's impacts on the state economy are substantial. In addition to the $595 million in gross state product, the company is estimated to generate over $33 million in taxes from the plants and their activities for Minnesota and its local governments. See Table 2.2.

Extra Income for Residents

The economic activity and low-cost electricity the plants create, to which Xcel Energy's nuclear operations at its headquarters contributes, also provide a boost to incomes of residents of Minnesota. In a consumer-driven economy, this is of the utmost importance. This boost is estimated to be $237 million annually in disposable personal income greater than if the plants and headquarters did not exist. This extra income provides Minnesotans with extra money to purchase necessities such as groceries and clothing for their families or save for college or retirement. More detail of this contribution to disposable personal income is in Table 2.3.

Large Multiplier Effects for Economic Activity and Jobs

By producing affordable, reliable electricity, Xcel Energy's nuclear operations are hubs of economic activity for Minnesota. Table 2.4 provides the multipliers and summarizes the total effects from each plant. The multipliers show that for every dollar of output generated, the plants stimulate between $2.03 and $2.30 in economic output in the state, while Xcel Energy headquarters produces $1.74 for every dollar. Minnesota employment multipliers range between 3.39 and 3.44 at the plants and 2.49 at Xcel Energy headquarters.

Section 3
Protecting the Environment

Like all nuclear power plants, Monticello and Prairie Island produce carbon-free electricity. Nuclear power produces 62 percent of the United States' carbon-free electricity and nearly 20 percent of total electricity generated. Hydro, wind and solar produce 19, 15, and 2 percent of carbon-free electricity, respectively. Nuclear power plants avoided 564 million metric tons of carbon dioxide in 2015, while hydro, wind and solar avoided 327 million metric tons combined. Annually, the avoided emissions from nuclear power is similar to adding 128 million cars to the nation's roads. Nuclear power plants also avoided hundreds of thousands of tons of nitrogen oxide and sulfur dioxide. The Environmental Protection Agency estimates that the Clean Power Plan will reduce carbon emissions by 414 million tons annually by 2030, or 73 percent of current carbon avoidance of the nuclear industry.

Xcel Energy's Nuclear Plants Contribution

In 2015, the operation of these three reactors prevented the emission of 12 million metric tons of carbon dioxide, about the same amount emitted by over 2 million cars each year. According to the Minnesota Pollution Control Agency's most recent data from 2012, Minnesota's electric sector emitted 47.6 million tons of carbon dioxide. The three reactors also prevent the emission of more than 11,100 tons of nitrogen oxide, equivalent to that released by 1.2 million cars, and 16,800 tons of sulfur dioxide. Sulfur dioxide and nitrogen oxide are precursors to acid rain and urban smog.

Clean Air Benefits of Xcel Energy Nuclear

Monticello and Prairie Island are the two largest carbon-free sources of generation in Xcel Energy's portfolio. In 2015, Monticello and Prairie Island produced over 12 million megawatt hours of electricity which avoided the emission of 11.6 million metric tons of carbon dioxide. They also prevent the release of thousands of tons of Nitrogen Oxide and Sulfur Dioxide.

In August 2016, the U.S. Court of Appeals for the Seventh Circuit validated the Social Cost of Carbon as a legitimate method to place a value on the benefits of carbon reduction.[1] Between 2016 and 2030, assuming Monticello and Prairie Island avoid the emission of 11.6 million metric tons of CO2 every year, these avoided emissions would represent an $8.67 billion in cumulative benefits. NEI calculated this value using the Social Cost of Carbon values from the Interagency Working Group Technical Support Document that was revised in July 2015. The values are in 2007 dollars and were inflated using the GDP deflator to 2015 dollars. The calculation is based on the 2015 carbon intensity of electricity generation in NERC's Midwest Reliability Organization.[2]

[1] *Zero Zone, Inc., et al., v. U.S. Department of Energy*

[2] *The Minnesota Public Utilities Commission is currently updating its CO2 externality range. Therefore, NEI has used the federal Social Cost of Carbon values as the Commission has not yet finalized its decision. The specific reference to the docket is: In the Matter of the Further Investigation into Environmental and Socioeconomic Costs Under Minn. Stat. § 216B.2422, Subd. 3. Minnesota Public Utilities Commission Docket No. E-999/CI-14-643.*

Section 4

Community Leadership and Environmental Protection

In addition to the economic benefits that Xcel Energy's nuclear operations contribute to Minnesota in the form of jobs, income and taxes, the company and its employees contribute to local communities in many other beneficial ways. Xcel Energy strengthens Minnesota communities through hiring veterans, charitable contributions, educational programs that teach and promote the benefits of nuclear energy, environmental programs that improve the quality of the environment, and civic engagement activities that build trust and goodwill.

Children using Monticello mobile simulator at open house event.

Corporate Citizenship

At a corporate level, Xcel Energy contributes significant time and resources to charitable endeavors. Over the past 10 years, Xcel Energy has raised $2.5 million annually for the United Way. Xcel Energy matches this amount, which means over $50 million has been contributed to local communities in the past decade. This annual campaign raises money with various events such as chili cook-offs and sporting tournaments. Each year, employees, contractors and retirees continue the tradition of giving, advocating and volunteering in the community.

The 2016 United Way campaign broke all previous records with the highest combined total of donations, surpassing the goal of $3 million. The result will be more than $5.6 million in matched contributions.

Prairie Island employees volunteering at Red Wing Memorial Park.

Below are further examples of contributions of Xcel Energy and its employees:

- In September 2015, more than 3,500 volunteers pitched in and spent 10,300 hours painting, sorting, planting and otherwise supporting 80 local non-profits during Xcel Energy's fifth annual Day of Service, making it the company's largest event ever.
- The Xcel Energy Foundation awarded $3.8 million in grants to nearly 430 non-profits benefitting four community focus areas that include STEM education, economic sustainability, environmental stewardship and access to arts and culture.
- Even after they retire, former Xcel Energy employees are giving back. The Pioneers in Public Service (PIPS) retiree volunteer program has been operating for over 30 years. PIPS members have dedicated more than 80,000 volunteer hours serving in communities.

Environmental Stewardship

Xcel energy generates 55 percent of its Upper Midwest electricity using carbon-free generation. Thirty percent of that generation is from its two nuclear plants in Minnesota, 15 percent is from wind energy, and 10 percent is from a combination of hydro/biomass/solar sources. Beyond its nuclear program, Xcel Energy has been the number one utility provider of wind energy for 12 straight years.

Xcel Energy employees volunteering for Habitat for Humanity.

In 2016, the U.S. Environmental Protection Agency awarded Xcel Energy the Climate Leadership Award for achieving its self-identified goal of 20 percent reduction in carbon by 2020 (which it achieved in 2014). Xcel Energy achieved these reductions through increasing renewable energy investment, modernizing its generation fleet, and offering incentives for customers to save energy.

Employment of Veterans

In 2016, Xcel Energy set a goal of hiring veterans as 15 percent of new hires. The company exceeded this goal. Military Times Magazine rated Xcel Energy as a top company for hiring veterans. Xcel Energy was listed among the Top 100 Military Friendly Employers by GI Jobs Magazine and ranked number 8 on Monster and Miltary.com's list of best companies for veteran hiring. Also, in 2016, the Minnesota Employer Support of the Guard and Reserve recognized Xcel Energy with the Pro Patria and Above and Beyond Awards for providing beneficial leave and support rules for military members required to perform military duties.

Contributions & Sponsorships

Xcel Energy nuclear plant employees volunteer and contribute to numerous community and local organizations and events. For example, Prairie Island engages in an annual golf tournament that benefits the United Way and a Make-A-Wish summer series. Both plants support Habitat for Humanity and both the Boy and Girl Scouts of America.

Section 5

Xcel Energy Nuclear Operations and the U.S. Nuclear Energy Industry

The three reactors play a vital role in helping Minnesota meet its demand for affordable, reliable and sustainable energy.

In 2015, electricity production from U.S. nuclear power plants was about 800 billion kilowatt-hours—nearly 20 percent of America's electricity supply. In Minnesota, nuclear energy generates approximately 21 percent of the state's electricity, and Xcel Energy's three reactors generated about 13 billion kilowatt-hours of electricity, which is approximately 54 percent of Minnesota's carbon-free electricity generation.

Xcel Energy's nuclear plants provide 54 percent of the carbon-free electricity generation in Minnesota.

Over the past 25 years, America's nuclear power plants have increased output and improved performance significantly. Since 1990, the industry has increased total output equivalent to that of 26 additional 1,000-MWe nuclear power plants, when in fact only five new reactors have come online. This is due to the fact that in 1990, U.S. nuclear plants were operating approximately 66 percent of the time compared to achieving a record capacity factor of over 92 percent in 2015.

Nuclear Energy's Value Proposition

Nuclear energy's role in the nation's electricity portfolio was especially valuable during the 2014 "polar vortex," when record cold temperatures gripped the United States and other sources of electricity were forced off the grid. Nuclear power plants nationwide operated at an average capacity factor of 96 percent during the period of extreme cold temperatures. During that time, supply volatility drove natural gas prices in many markets to record highs and much of that gas was diverted from use in the electric sector so that it could be used for home heating.

Some of America's electricity markets, however, are structured in ways that place some nuclear energy facilities at risk of premature retirement, despite excellent operations. It is imperative that policymakers and markets appropriately recognize the full strategic value of nuclear energy in a diverse energy portfolio.

That value proposition starts with the safe and reliable production of large quantities of electricity around the clock.

One of nuclear energy's key benefits is the availability of low-cost fuel (which does not need to be delivered continuously and the ability to produce electricity under virtually all weather conditions. Renewable energy, an emerging part of the energy mix, is intermittent (the sun doesn't always shine and the wind

doesn't always blow when generation is needed) and therefore cannot be readily dispatched to meet demand; natural gas-fired generation depends on fuel being available (both physically and at a reasonable price); and on-site coal piles can freeze.

Nuclear power plants also provide clean-air compliance value. Minnesota's Next Generation Energy Act of 2007 set a goal that would reduce greenhouse gas emissions 15 percent below the 2005 level in 2015, and 30 and 80 percent below that level in 2025 and 2050, respectively.

Nuclear plants provide voltage support to the grid, helping to maintain grid stability. They have portfolio value, contributing to fuel and technology diversity. And they provide a tremendous local and regional economic development opportunity, including large numbers of high-paying jobs and significant contributions to the local and state economies and tax base.

Based on more than 50 years of experience, the nuclear industry is one of the safest industrial working environments in the nation.

Stable Prices for Consumers

In addition to increasing electricity production at existing nuclear energy facilities, power from these facilities is affordable and stable for consumers. Compared to the cost of electricity produced using fossil fuels—which are heavily dependent on market fuel prices—nuclear plants' fuel costs are relatively stable, making consumers' electric bills more predictable. Uranium fuel is only about one-third of the production cost of nuclear energy, while fuel costs have historically made up between 75-85 percent of coal-fired and natural gas production costs. Production costs for a nuclear plant have historically been $0.03/kWh or lower. Natural gas production costs are currently historically low at $0.03/kWh, but have been over $0.08/kWh in 2000, 2001, 2005 and 2008.

Safety and Security

Safety is the highest priority for the nuclear energy industry. Based on more than 50 years of experience, the industry is one of the safest industrial working environments in the nation. Through rigorous training of plant workers and increased communication and cooperation among nuclear plants and federal, state and local regulating bodies, the industry is keeping the nation's 99 nuclear plants safe for their communities and the environment.

The U.S. Nuclear Regulatory Commission (NRC) provides independent federal oversight of the industry and tracks data on the number of "significant events" at each nuclear plant. (A significant event is any occurrence that challenges a plant's safety systems.) The average number of significant events per reactor declined from 0.45 per year in 1990 to 0.01 in 2014, illustrating the emphasis on safety throughout the nuclear industry.

General worker safety is also excellent at nuclear power plants—far safer than in the manufacturing sector. U.S. Bureau of Labor Statistics data show that, in 2013, nuclear energy facilities achieved an incidence rate of 0.3 per 200,000

work hours, compared to 1.8 for fossil-fuel power plants, 1.8 for electric utilities and 4.0 for the manufacturing industry.

All American nuclear plants are designed and operated with public safety first and foremost in mind. The plants have redundant and diverse safety systems which are backed by multiple power sources.

U.S. nuclear plants also have over 9,000 highly trained paramilitary personnel protecting the plants from external threats. These plants also maintain emergency response plans that are reviewed and approved by the Nuclear Regulatory Commission and coordinated with the Federal Emergency Management Agency. In order to maintain this high level of safety and security within its community, each plant coordinates with its local police, fire, and EMS departments.

Industry Trends: License Renewal and New Plants

The excellent economic and safety performance of U.S. nuclear power plants has demonstrated the value of nuclear energy to the electric industry, the financial community and policymakers. This is evidenced by the increasing number of facilities seeking license renewals from the NRC.

Of the currently operating reactors nationwide, 84 out of 99 have received license renewal. The Nuclear Regulatory Commission found no technical limitations to prevent a nuclear plant from operating for 80 years.

Originally licensed to operate for 40 years, nuclear energy facilities can operate safely for longer. The NRC granted the first 20-year license renewal to the Calvert Cliffs plants in Maryland in 2000. As of March 2017, 84 currently operating reactors had received license extensions, and operators of 13 additional reactors either had submitted applications or announced that they will seek renewal. License renewal is an attractive alternative to building new electric capacity because of nuclear energy's low production costs and the return on investment provided by extending a plant's operational life.

The Nuclear Regulatory Commission has found that there are no technical reasons to prevent a nuclear plant from operating for 80 years. In 2014, the Nuclear Regulatory Commission found that its current regulatory structure regarding initial license renewal is suitable for second license renewal. In 2015, Dominion announced that it will apply in 2019 for a second license renewal for its Surry Power Station in Virginia. If granted, this will allow the plant to operate for an additional 20 years (80 years in total). Exelon announced in June 2016 that it will pursue second license renewal for its Peach Bottom plant.

Besides relicensing nuclear plants, energy companies are building new, advanced-design reactors. Georgia Power and South Carolina Electric & Gas are building two advanced reactors each, near Augusta, Ga., and Columbia, S.C. These facilities are nearly halfway through their construction programs. These projects employ more than 5,000 workers each now that construction is peaking. In addition, Tennessee Valley Authority began operation of the Watts Bar 2 reactor in Tennessee in June 2016.

Section 6

Economic Impact Analysis Methodology

This analysis uses the REMI model to estimate the economic and fiscal impacts of Xcel Energy's nuclear facilities.

Regional Economic Models, Inc. (REMI)

REMI is a modeling firm specializing in services related to economic impacts and policy analysis, headquartered in Amherst, Mass. It provides software, support services, and issue-based expertise and consulting in almost every state, the District of Columbia, and other countries in North America, Europe, Latin America, the Middle East and Asia.

REMI's software has two main purposes: forecasting and analysis of alternatives. All models have a "baseline" forecast of the future of a regional economy at the county level. Using "policy variables," in REMI terminology, provides scenarios based on different situations. The ability to model policy variables makes it a powerful tool for conveying the economic "story" behind policy. The model translates various considerations into understandable concepts like GDP and jobs.

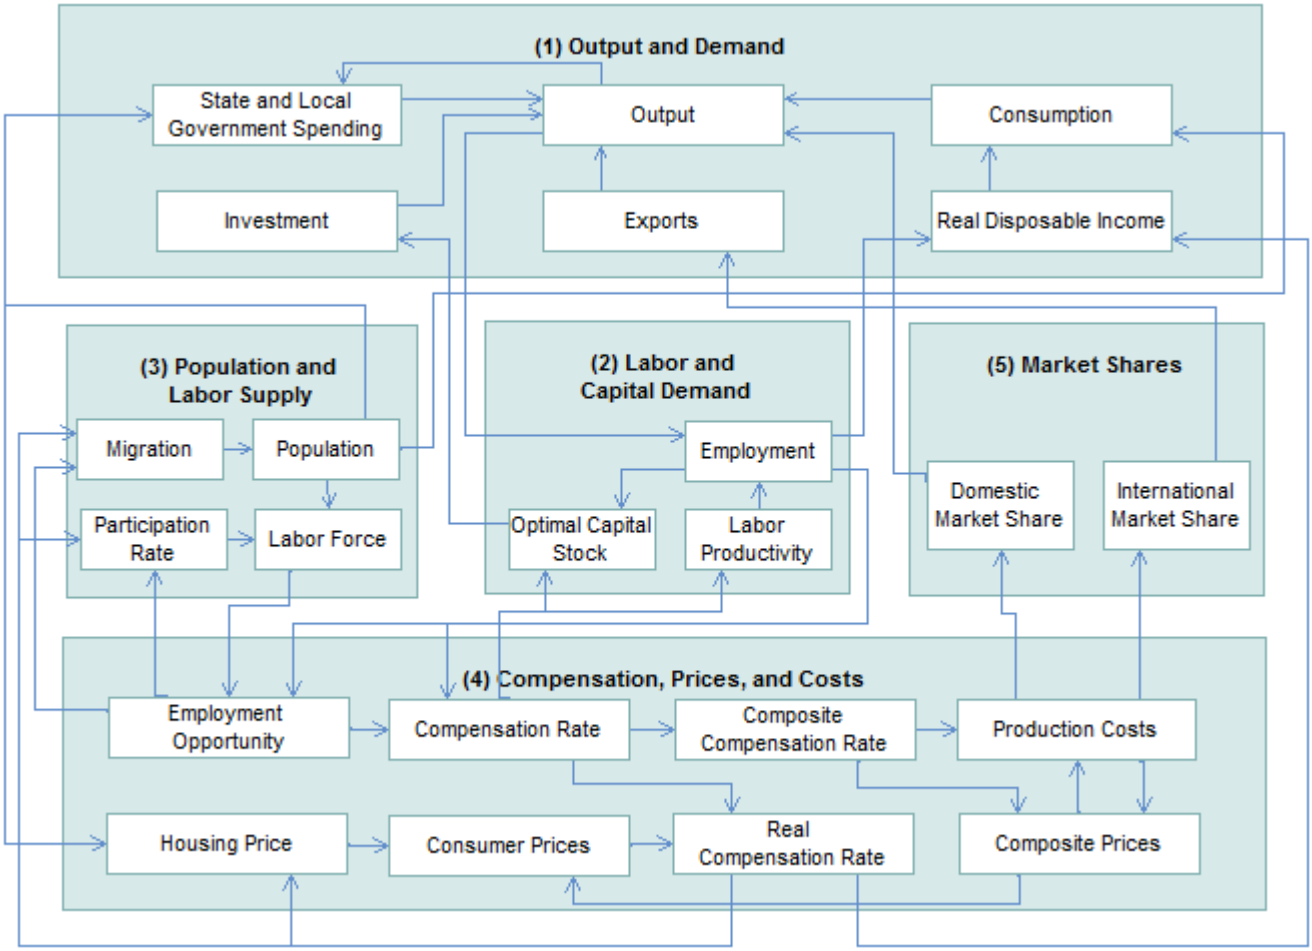
REMI relies on data from public sources, including the Bureau of Economic Analysis, Bureau of Labor Statistics, Energy Information Administration and the Census Bureau. Forecasts for future macroeconomic conditions in REMI come from a combination of resources, including the Research Seminar in Quantitative Economics at the University of Michigan and the Bureau of Labor Statistics. These sources serve as the main framework for the software model needed to perform simulations.

Policy Insight Plus (PI+)

REMI's PI+ is a computerized, multiregional, dynamic model of the states or other sub-national units of the United States economy. PI+ relies on four quantitative methodologies to guide its approach to economic modeling:

1. Input/output tabulation (IO)—IO models, sometimes called "social accounting matrices" (SAM), quantify the interrelation of industries and households in a computational sense. It models the flow of goods between firms in supply-chains, wages paid to households, and final consumption by households, government and the international market. These channels create the "multiplier" effect of $1 going farther than when accounting for its impact on enabling subsequent value..
2. Computable general equilibrium (CGE)—CGE modeling adds market concepts to the IO structure. This includes how those structures evolve over time and how they respond to alternative policies. CGE incorporates con-

Figure 6.0



This diagram represents the structure and linkages of the regional economy in PI+. Each rectangle is a discrete, quantifiable concept or rate, and each arrow represents an equation linking the two of them. Some are complex econometric relationships, such as the one for migrant, while some are rather simple, such as the one for labor force, which is the population times the participation rate. The change of one relationship causes a change throughout the rest of the structure because different parts move and react to incentives at different points. At the top, Block 1 represents the macroeconomic whole of a region with final demand and final production concepts behind GDP, such as consumption, investments, net exports and government spending. Block 2 forms the "business perspective": An amount of sales orders arrive from Block 1, and firms maximize profits by minimizing costs when making optimal decisions about hiring (labor) and investment (capital). Block 3 is a full demographic model. It has births and deaths, migration within the United States to labor market conditions, and international immigration. It interacts with Block 1 through consumer and government spending levels and Block 4 through labor supply. Block 4 is the CGE portion of the model, where markets for housing, consumer goods, labor and business inputs interact. Block 5 is a quantification of competitiveness. It is literally regional purchase coefficients (RPCs) in modeling and proportional terms, which show the ability of a region to keep imports away while exporting its goods to other places and nations.

cepts on markets for labor, housing, consumer goods, imports and the importance of competitiveness to fostering economic growth over time. Changing one of these will influence the others—for instance, a new knife factory would improve the labor market and then bring it to a head by increasing migration into the area, driving housing and rent prices higher, and inducing the market to create a new subdivision to return to "market clearing" conditions.

3. Econometrics—REMI uses statistical parameters and historical data to populate the numbers inside the IO and CGE portions. The estimation of the different parameters, elasticity terms and figures gives the strength of various responses. It also gives the "time-lags" from the beginning of a policy to the point where markets have had a chance to clear.

4. New economic geography—Economic geography provides REMI a sense of economies of scale and agglomeration. This is the quantification of the strength of clusters in an area and their influence on productivity. One example would include the technology and research industries in Seattle. The labor in the area specializes to serve firms like Amazon and Microsoft and, thus, their long-term productivity grows more quickly than that of smaller regions with no proclivity towards software development (such as Helena, Mont.). The same is true on the manufacturing side with physical inputs, such as with the supply-chain for Boeing and Paccar in Washington in the production of transportation equipment. Final assembly will have a close relationship and a high degree of proximity to its suppliers of parts, repairs, transportation and other professional services, which show up in clusters in the state.

Conclusion

The estimated total economic impacts (direct and secondary) to Minnesota from Xcel Energy's nuclear operations at its three reactors and support operations at Xcel Energy headquarters are over $1 billion in output and approximately $600 million in gross state product every year. These operations also contribute $240 million in after-tax income to residents of Minnesota. The nuclear operations and their secondary effects also account for over 6,000 jobs in Minnesota.

The plant's economic benefits—on taxes and through wages and purchases of supplies and services—are considerable. In addition, plant employees further stimulate the local economy by purchasing goods and services from businesses around the area, supporting many small businesses throughout the region.

The facilities generated nearly 13 billion kilowatt-hours of emission-free electricity in 2015, enough to serve the yearly needs for 1.4 million homes. This low-cost, reliable electricity helped keep electricity prices in check in Minnesota.

Xcel Energy's nuclear plants are leaders economically, fiscally, environmentally and socially within Minnesota.

APPENDIX P1 – E3 SUMMARY

I. OVERVIEW OF ANALYSIS CONDUCTED BY ENERGY AND ENVIRONMENTAL ECONOMICS

We retained Energy and Environmental Economics, Inc. (E3) to provide analysis to inform our Resource Plan. E3 is a recognized industry-leading firm based in San Francisco and consults extensively with utilities, developers, government agencies, and environmental groups on clean energy issues. E3's experience analyzing the impacts of economy-wide decarbonization and the impacts of decarbonization on utility systems in other parts of the country was very valuable to us in evaluating the impacts of decarbonizing our Upper Midwest System and developing our Preferred Plan.

E3's analysis is provided in two reports. The first report provides their analysis on decarbonizing our Upper Midwest System (System Study). For this analysis, E3 performed an electricity portfolio optimization analysis that identifies a range of strategies to meet our greenhouse gas reductions goals. The second report provides E3's analysis on achieving the Minnesota economy-wide goal of an 80 percent reduction in greenhouse gases below 2005 levels by 2050 (Pathways Study). E3 presented its analysis at stakeholder workshops in September and October of 2018 and April 2019.

A. Upper Midwest System Study

For the System Study, E3 performed independent modeling and analysis of our system to inform our Resource Plan using two models:

- The RESOLVE model, which evaluates and optimizes the least-cost portfolios of resources to meet system demand considering carbon and other constraints,
- The RECAP model, which evaluates the reliability of electric energy and system capacity of the optimized resource portfolios over thousands of simulated weather years.

E3 used scenario analysis to examine the impacts of achieving deep carbon reductions in our generation portfolio in accordance with our long-term goals. Each scenario examined was designed to achieve carbon reduction milestones of 85% below 2005 levels by 2030 and 95% below 2005 levels by 2045. As discussed in detail in the report, these scenarios varied assumptions on the retirement of our nuclear and coal plants and the ability to add new gas-fired resources, the impacts of high electrification, gas prices, technology costs, and the ability to sell surplus generation into the MISO market.

The System Study contains several key findings that inform our Resource Plan:

1. **The study suggests that we can achieve substantial reductions in carbon emissions from our Upper Midwest portfolio at relatively low cost.** Across the 21 scenarios examined in this study that achieve deep carbon reductions during the study horizon, the lowest-cost scenarios reduce carbon at a levelized cost of $15-20 per ton. The ability to achieve such large emissions reductions at such a relatively low cost results from several converging factors: (1) low natural gas prices, which enable low-cost fuel switching from coal to gas; (2) the relatively low (and falling) costs of new wind and solar resources due to technology improvements over the past decade; (3) a potential to increase deployment of energy efficiency and other demand-side programs to manage load growth; and (4) anticipated reductions in future battery storage costs, which enable integration of high penetrations of renewable generation.
2. **The lowest-cost near-term opportunity to reduce carbon in Xcel's Upper Midwest system is to replace coal generation with a combination of renewables, storage, natural gas and efficiency.** E3's analysis suggests that accelerating the retirement of our remaining coal plants and replacing them with a portfolio of efficiency, renewables, storage, and natural gas generation provides the least-cost pathway to reducing emissions consistent with our 2030 goals.
3. **A diverse portfolio of resources—including nuclear—offers the least-cost long-term pathway to deep carbon reductions.** The scenario analysis conducted in this study suggests that under most circumstances, extending the licenses of both Monticello and Prairie Island to allow continued operation provides a least-cost option to meeting long-term carbon goals. This is due not only to the plants' ability to generate carbon-free electricity at relatively low cost but also, and perhaps more significantly, to the fact that nuclear generation (unlike wind, solar, or energy storage), as a "firm" resource, can generate at its full nameplate capacity for sustained periods when needed to meet reliability needs. This unique combination of characteristics makes existing nuclear plants inherently valuable to meeting our long-term carbon goals. All else equal, levelized cost of carbon abatement was higher in scenarios that did not allow nuclear relicensing.
4. **While new resources like wind, solar, and storage will play a central role in supplying carbon-free energy to Xcel's customers, these resources alone cannot meet Xcel's resource adequacy needs at reasonable costs.** The reliability analysis conducted in the study highlights the limitations of renewable and storage resources to meet resource adequacy needs: due to

variability of renewable generation and limits on duration of energy storage with today's technologies, these resources offer less capacity value than firm resources that can produce at full capacity when needed. Further, because their marginal capacity value declines with increasing penetration, wind, solar, and storage offer a relatively poor substitute for traditional firm capacity resources in meeting reliability needs at scale. Taken to an extreme, this study shows that a system designed to rely solely on renewables and storage to meet reliability needs would require prohibitively large investments. These findings underscore the need for an evolving approach to resource adequacy as the system as a whole incorporates greater amounts of renewables and storage. Such an approach would ensure that sufficient resources are available even when variable renewables and storage alone cannot produce sufficient levels of generation to meet load.

5. **Natural gas plants will be useful to ensure a reliable system but will operate at low capacity factors.** Some form of firm, dispatchable capacity is likely necessary to complement large anticipated investments in efficiency, renewables, and storage that will be necessary to decarbonize Xcel's energy supply. **Error! Reference source not found.** shows that among all low-carbon scenarios considered in this study, the least-cost options rely heavily on firm capacity resources to meet resource adequacy needs. In Xcel's case, investing in 2,000 to 4,000 MW of new gas generation capacity will lower the costs of achieving long-term carbon goals. All else equal, the levelized cost of carbon abatement was higher in scenarios that did not allow new gas. In the extreme, providing reliable electricity in a scenario with no dispatchable gas was modeled to require 36 GW of wind and solar, 24 GW of storage, and impose $4.4 billion per year in incremental fixed costs. As technology continues to improve, some of the electricity system values provided by gas generation may be able to be provided by a combination of longer-duration storage, demand response, and carbon-free dispatchable technologies that are not commercial today.

B. PATHWAYS Study

For the PATHWAYS study, E3 developed a set of long-term economy-wide, deep decarbonization scenarios for the state of Minnesota. These scenarios provide an exploration of the cross-sectoral implications of meeting economy-wide carbon reduction goals, and highlight the role of Xcel Energy, and the electric sector as a whole, in meeting the state's economy-wide carbon goal. The PATHWAYS study highlights the central role of the electric sector in reducing economy-wide greenhouse gas emissions by supplying clean energy to new loads as more fossil-fueled end uses convert to electricity.

Key finds from the PATHWAYS study include:

1. **Electrification and low-carbon electricity are necessary (but not sufficient) to reach statewide goals.** The analysis demonstrates how increased reliance on low-carbon electricity enables emission reductions by avoiding direct combustion of fossil fuels in households, businesses, and vehicles across a number of scenarios. Under a high electrification scenario, switching multiple end uses to very low-carbon electricity could enable an estimated 35 million tons of CO_2 reductions per year in other sectors by 2050, in addition to reductions in the electric sector itself.
2. **Buildings and transportation have significant potential to drive load growth, especially after 2025.** The analysis also highlights the significant potential for adoption of new electric appliances and vehicles, and the potential impact on total electricity requirements for Minnesota utilities. Transportation and building electrification drive electric load growth, especially after 2030, particularly in a future with constraints on bioenergy. Electrification of space heating has a particularly large impact on both total load (MWh) and peak demand (MW), primarily due to two factors: cold-climate efficiency challenges with electric air source heat pumps, and the greater difficulty (compared to electrified transportation or water heating) of limiting heating loads to off-peak hours.
3. R**easonable electric rates and low costs for new electric devices are essential for electrification.** The levels of electrification modeled in buildings and transportation are dependent on consumer adoption, which will benefit from reductions in capital costs and reasonable electric rates, even as the electric grid continues to decarbonize.

C. Relation to the Company's Resource Plan Analysis

By design, the scope of analysis conducted in E3's System Study overlaps considerably with the internal analysis conducted to develop our Preferred Plan. Wherever possible, the E3 studies relied on the same numerical inputs and assumptions as used to develop our Preferred Plan, supplemented by publicly available data sources where necessary. This approach was chosen to test the hypothesis that Xcel's internal analysis should generally align with the results obtained by an unbiased third-party using rigorous industry-standard approaches.

The PATHWAYS study provides context for the role of the electricity sector in reducing statewide carbon emissions. The PATHWAYS study explores scenarios that

could achieve an 80 percent reduction in economy-wide greenhouse gas emissions, but it is not a least-cost optimization. As discussed in Appendix F4, the PATHWAYS study was also used to develop a high electrification load forecast sensitivity that was analyzed in E3's System Study and our Strategist modeling.

Executive Summary

Study Overview

Across the United States, the electricity sector is in a rapid state of transition, driven by multiple factors:

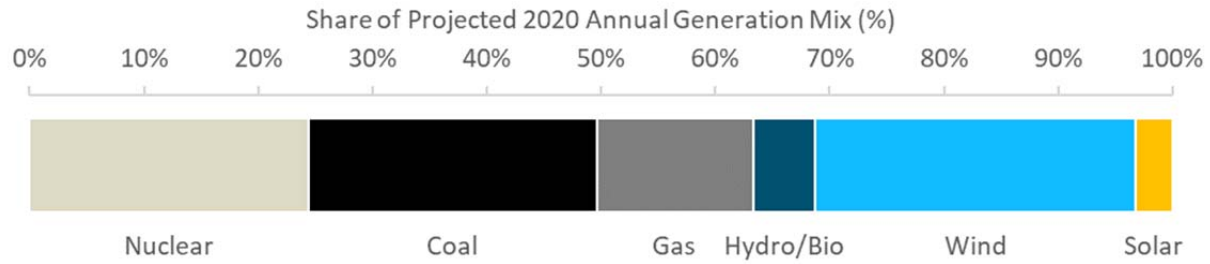
- An increasing preference for "clean" energy resources and interest in decarbonization of electricity supply at the state, utility, and customer levels;
- Significant realized cost reductions of renewable resources such as wind and solar, coupled with the emergence of new technologies such as battery storage; and
- Aging generation infrastructure leading to plant retirements and a corresponding need for investment in new generation resources.

These trends, and the elevated levels of investment in new renewable generation they have prompted throughout the country in the past decade, are likely to continue.

Since 2005, Xcel Energy's Upper Midwest system, which serves customers in Minnesota and four neighboring states, has made significant progress toward decarbonizing its energy supply. The company's conversion of its High Bridge and Riverside coal plants, achievement of energy efficiency consistent with state standards, and investment in a total of over 3,000 MW of wind generation have led to a collective shift towards carbon-free generation resources, which are expected to represent approximately 60% of the Upper Midwest system's generation mix by 2020. The expected annual generation mix for the Upper Midwest system in 2020 is shown in Figure i.

© 2019 Energy and Environmental Economics, Inc.

Figure i. Projected annual generation mix in 2020



This shift has enabled significant carbon reductions in the Upper Midwest portfolio, whose 2017 emissions were roughly 30% below a 2005 benchmark level. Xcel also recently established notable forward-looking goals that imply significant continued effort in this area over the long term:

- Xcel's 2015 Upper Midwest Integrated Resource Plan established plans to retire two coal plants and meet 60% of customer loads with carbon-free resources by 2030; and
- In December 2018, Xcel announced a company-wide goal to reduce emissions by 80% by 2030 and to be 100% carbon-free by 2050, a first-of-its-kind target among U.S. utilities.

Achieving these ambitious goals will require careful and strategic approaches to planning, procurement, and utility operations. While low-cost wind, solar and energy storage resources will make up the bulk of investments needed to meet Xcel's goals, additional capabilities will be needed to supplement these resources whose availability depends on uncontrollable meteorological phenomena. Balancing load and generation instantaneously and ensuring resource adequacy under all conditions (e.g., during periods of high load and low wind and solar output) requires an evolution in today's operational and planning practices. Designing a low-cost resource portfolio that simultaneously meets future reliability standards and clean energy objectives has become one of the principal long-term planning challenges for utilities today.

This report, commissioned of E3 by Xcel Energy addresses several key questions implied by the company's aggressive carbon targets:

- What would be the composition of the Upper Midwest system portfolio—and what are its corresponding greenhouse gas emissions—under a "Reference Case" scenario reflecting a business-as-usual, least-cost approach to meeting future energy and capacity needs?
- What are Xcel's options—and what are the corresponding costs—for achieving steep emission reductions consistent with near- and long-term goals?
- What are the reliability implications of relying heavily on renewable and storage resources? Could an electric system achieve 100% emissions reductions using only today's commercially available technologies while maintaining reliability?

To answer these questions, this study uses scenario analysis to design and characterize a range of different portfolios that each achieve aggressive levels of decarbonization relative to a Reference Case. The portfolios are constructed from different assumptions about potential coal and nuclear plant retirements and future investments in natural gas resources, which in turn determine the quantity and timing of future renewables and storage additions and investments in demand-side resources needed to meet long-term carbon reduction goals.

By design, the scope of analysis conducted in this study overlaps considerably with the internal analysis conducted by Xcel Energy in the development of its preferred plan as filed in its Integrated Resource Plan. Wherever possible, this study relies on the same numerical inputs and assumptions as used by Xcel's IRP team, supplemented by publicly available data sources where necessary. This approach was chosen to ensure that the results of Xcel's internal analysis align with the rigorous, industry-standard approaches.

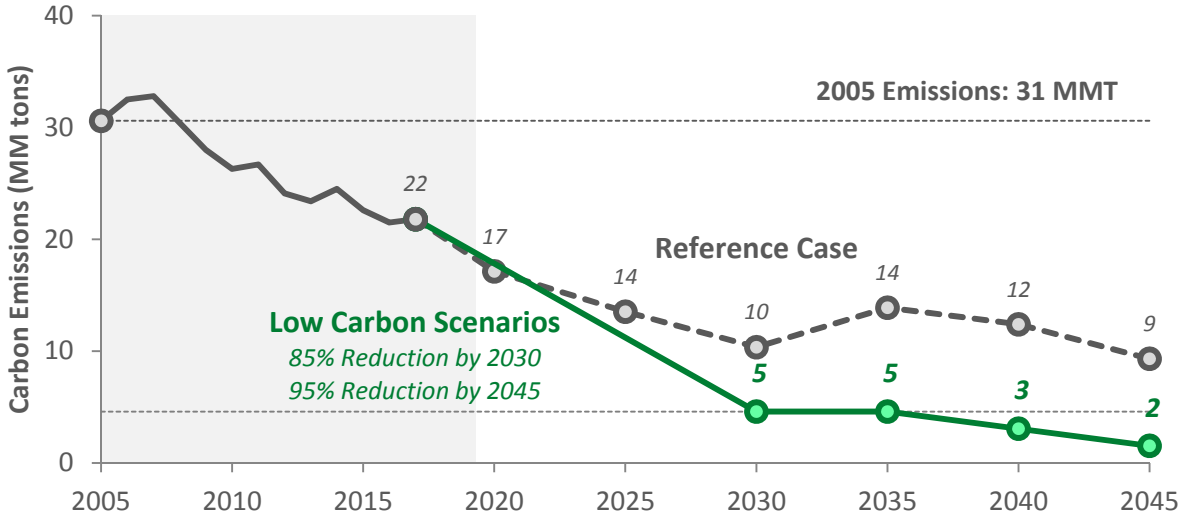
Methods and Assumptions

This study uses scenario analysis to examine the impacts of achieving deep carbon reductions in Xcel's portfolio in accordance with the company's long-term goals. Keeping in mind the breadth of resource options available to meet Xcel's future energy and capacity needs, and consequently the many different pathways to achieve the company's targeted carbon reductions, this analysis designs and evaluates a range of different plausible portfolios. Each scenario examined in this study (with the exception of a counterfactual Reference Case) is designed to achieve carbon reduction milestones of 85% below 2005 levels by 2030 and 95% below 2005 levels by 2045. The trajectory of carbon reductions that each scenario is designed to achieve is shown in Figure ii.

Figure ii. Future Upper Midwest carbon reduction pathway as modeled in this study compared to counterfactual Reference Case



While all scenarios are consistent with the carbon reduction trajectory above, each scenario achieves the desired level of carbon reductions with a unique combination of resource options (i.e., nuclear, fossil, renewable, storage, and demand-side resources). Figure iii shows the range of assumptions used

in this study about each of those resources. Overall, this study compares 21 distinct scenarios against a Reference Case that provides a benchmark against which costs and emissions reductions are measured. The purpose of constructing scenarios in this way is to highlight tradeoffs implied by Xcel's key strategic decisions as it transitions toward a low-carbon future:

- What is the long-term role of nuclear generation in Xcel's portfolio?
- How would the continued operation of Xcel's coal resources impact its efforts to decarbonize?
- What role, if any, should new natural gas play in meeting long-term resource adequacy needs?
- What renewables, storage, and demand-side resources are needed to meet carbon goals?

Figure iii. Range of assumptions about Xcel's resource options captured in scenario analysis

Resource	Scenario Options			
Nuclear	Retire upon license expiry	Relicense Monticello only	Relicense both nuclear plants	Retire Prairie Island by 2030
Coal	Retire all plants at end of useful life	Retire AS King by 2030	Retire all coal by 2030	
Gas	Allow investment in new gas	Limit new gas additions to Sherco CC	Prohibit all new gas investment	
Wind	Add new wind to meet energy, capacity, and clean energy goals			
Solar	Add new solar to meet energy, capacity, and clean energy goals			
Storage	Add new storage to meet capacity & flexibility needs			
DR	Add new DR to meet capacity needs			
Efficiency	Deploy energy efficiency to meet energy, capacity & clean energy needs			

© 2019 Energy and Environmental Economics, Inc.

This study utilizes two resource planning models developed to analyze electric systems at high penetrations of renewable generation:

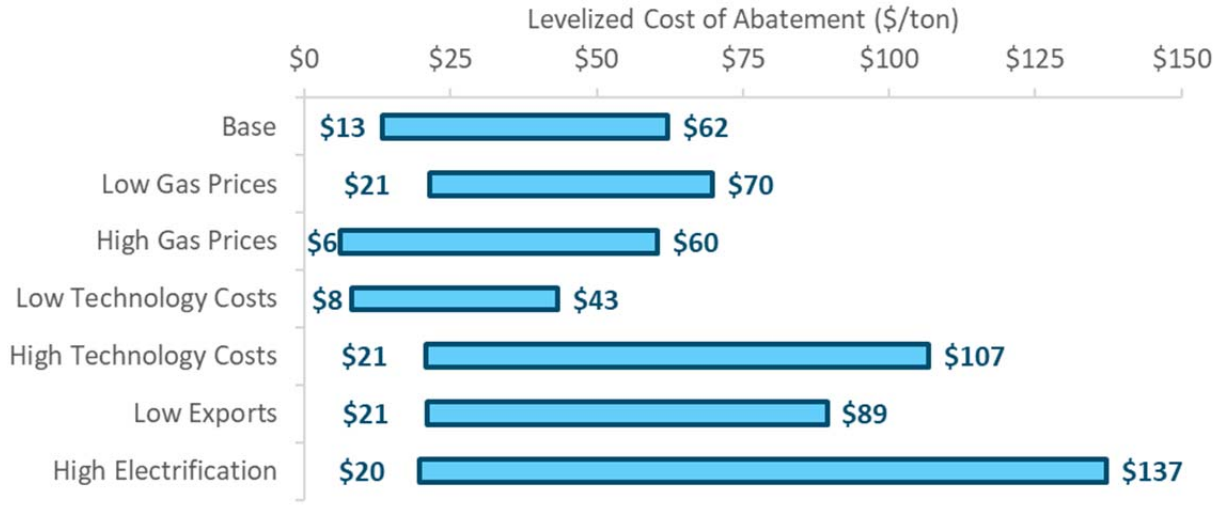
- **E3's Renewable Energy Capacity (RECAP) model**, a loss-of-load-probability model that provides a detailed and statistically robust perspective on the reliability of electric systems with conventional, renewable, storage, and demand-side resources; and
- **E3's Renewable Energy Solutions (RESOLVE) model**, a capacity expansion model that uses optimization techniques to identify a least-cost portfolio of resource investments to meet future reliability and clean energy objectives while also simulating electric system operations on an hourly basis.

These tools complement one another and jointly provide a strong foundation for analyzing and understanding the implications of a long-term transition towards low-carbon and carbon-free resource portfolios. In this study, RECAP provides a rigorous, data-driven perspective on the future reliability needs of the Xcel portfolio and the ability of wind, solar, and storage to meet those needs; RESOLVE builds on this analysis to design least-cost portfolios that achieve reliability objectives while meeting clean energy goals, balancing large quantities of variable resources, and minimizing costs.

Key Findings

First—and perhaps most significantly—this study suggests that Xcel Energy can achieve substantial reductions in carbon emissions from its Upper Midwest portfolio at relatively low cost. Across the 21 scenarios examined in this study that achieve deep carbon reductions during the study horizon, the lowest-cost scenarios reduce carbon at a levelized cost of $15-20 per ton. The ability to achieve such large emissions reductions at such a relatively low cost results from several converging factors: (1) low natural gas prices, which enable low-cost fuel switching from coal to gas; (2) the relatively low (and falling) costs of new wind and solar resources due to technology improvements over the past decade; (3) a potential to increase deployment of energy efficiency and other demand-side programs to manage load growth; and (4) anticipated reductions in future battery storage costs, which enable integration of high penetrations of renewable generation.

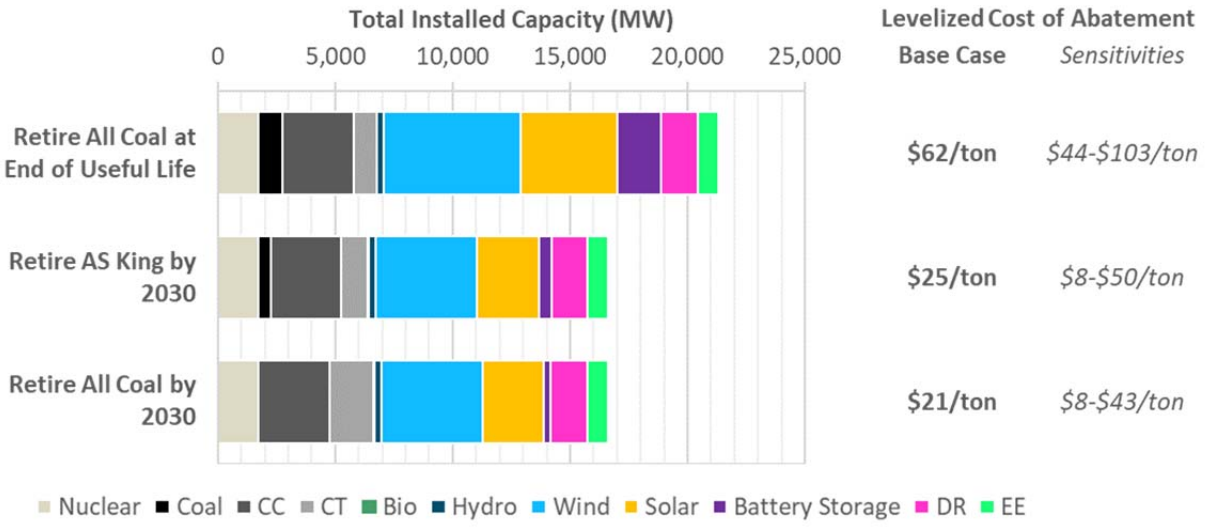
Figure iv. Range of carbon abatement costs across all scenarios and sensitivities.



© 2019 Energy and Environmental Economics, Inc.

The lowest-cost near-term opportunity to reduce carbon in Xcel's Upper Midwest system is to replace coal generation with a combination of renewables, storage, efficiency, and natural gas generation. The four coal plants owned by Xcel produce approximately 85% of the Upper Midwest system's greenhouse gas emissions in the 2020 Reference Case; while Xcel has already established plans to retire two of these plants prior to 2030, this analysis suggests that accelerating the retirement of its remaining two plants and replacing them with a portfolio of efficiency, renewables, storage, and natural gas generation provides the least-cost pathway to reducing emissions consistent with Xcel's 2030 goals (see Figure v).

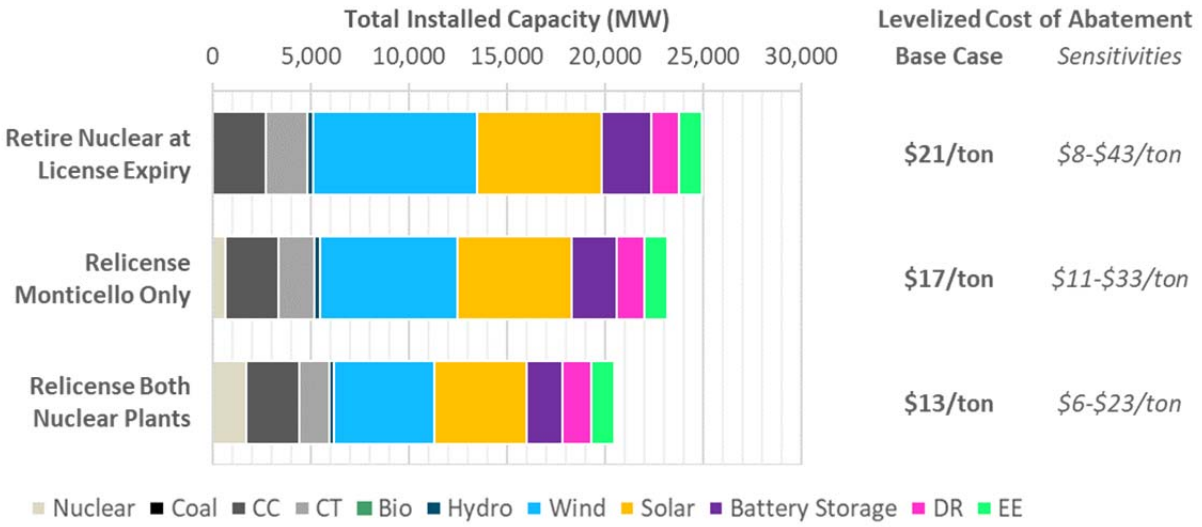
Figure v. Xcel resource portfolios that achieve 85% carbon reductions in 2030



A diverse portfolio of resources—including nuclear—offers the least-cost long-term pathway to deep carbon reductions. Beyond 2030, meeting Xcel's long-term carbon goals will require continued development of new carbon-free energy resources. At the same time, the expiration of existing licenses at both of Xcel's nuclear facilities in the early 2030s raises questions about the role of nuclear in Xcel's long-term generation portfolio. The scenario analysis conducted in this study suggests that under most

circumstances, extending the licenses of both Monticello and Prairie Island to allow continued operation provides a least-cost option to meeting long-term carbon goals (Figure vi). This is due not only to the plants' ability to generate carbon-free electricity at relatively low cost but also, and perhaps more significantly, to the fact that nuclear generation (unlike wind, solar, or energy storage) operates as a "firm" resource that can generate at its full nameplate capacity for sustained periods when needed to meet Xcel's reliability needs. This unique combination of characteristics makes Xcel's existing nuclear plants inherently valuable to meeting Xcel's long-term carbon goals.

Figure vi. Xcel resource portfolios that achieve 95% carbon reductions in 2045

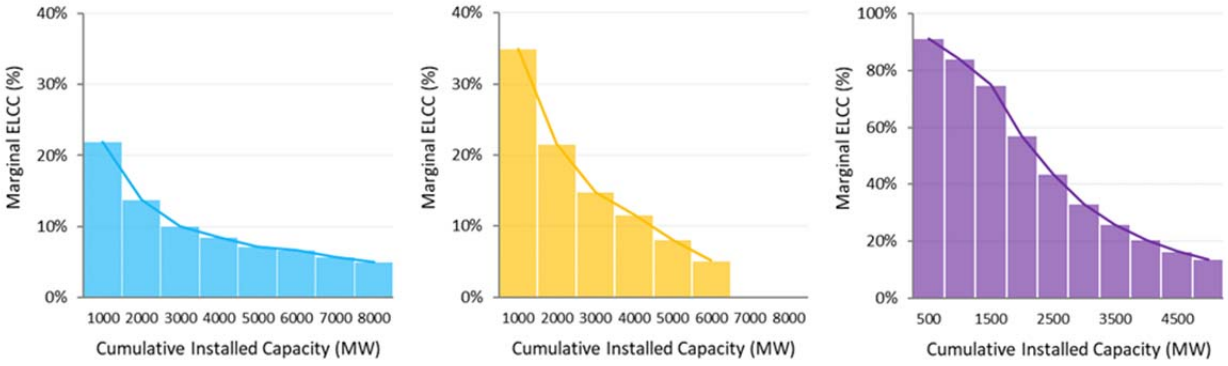


While new resources like wind, solar, and storage will play a central role in supplying carbon-free energy to Xcel's customers, these resources alone cannot meet Xcel's resource adequacy needs at reasonable costs. The reliability analysis conducted in this study highlights the limitations of renewable and storage resources to meet resource adequacy needs: due to variability and limits on duration, these resources offer less capacity value than firm resources that can produce at full capacity when needed. Further, because their marginal capacity value declines with increasing penetration, wind, solar, and

© 2019 Energy and Environmental Economics, Inc.

storage offer a relatively poor substitute for traditional firm capacity resources in meeting reliability needs at scale (see Figure vii). Taken to an extreme, this study shows that a system designed to rely solely on renewables and storage to meet reliability needs would require prohibitively large investments. These findings underscore the need for an evolving approach to resource adequacy—by both Xcel and MISO—as renewables and storage reach greater levels of penetration. Such an approach is critical to ensure that sufficient resources are available even when variable renewables and storage alone cannot produce sufficient levels of generation to meet load.

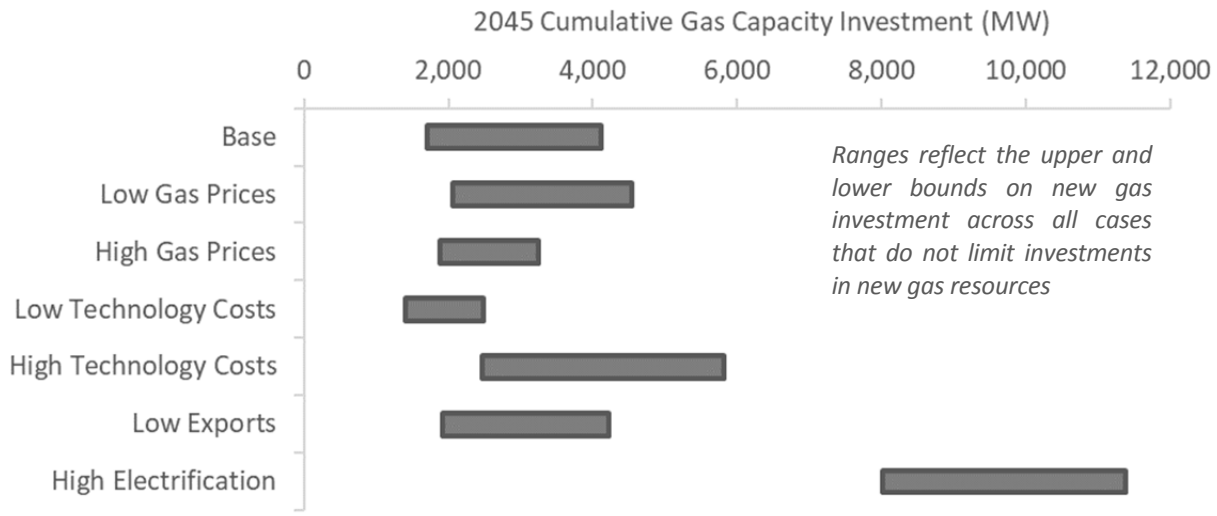
Figure vii. Marginal capacity values of wind, solar, and storage resources in Xcel's 2030 portfolio



Natural gas plants will be critically important to ensure a reliable system but will operate at low capacity factors. Because of the inherent limitations of renewables and storage resources to satisfy resource adequacy needs alone, some form of firm, dispatchable capacity will be needed to complement large anticipated investments in efficiency, renewables, and storage that needed to decarbonize Xcel's energy supply. While Xcel's existing nuclear plants are highly valuable because of their firm attributes, they alone are not sufficient to satisfy the need for firm capacity; natural gas resources will continue to play a crucial role in meeting system reliability. Figure viii shows the range of new investments in natural gas resources across all the cases and sensitivities that allowed gas investment as part of the least-cost plan. Under Base Case assumptions, the level of new gas

investments needed by 2045 spans a range from 2,000 to 4,000 MW (depending on whether existing nuclear plants are relicensed); among most other sensitivities, a similar range is observed. One sensitivity stands out for its outsized effect: in the High Electrification sensitivity, due to large new loads that increase winter peak significantly, the level of investment in new gas resources in least-cost portfolios is dramatically higher—8,000 to 11,000 MW. Collectively, these observations point to a more general finding: investment in new natural gas resources to meet capacity needs enables a low-cost pathway to decarbonize electricity and to facilitate levels of electrification needed to meet economy-wide carbon reduction goals.

Figure viii. Range of investments in new natural gas capacity resources by 2045 as part of a least-cost plan to achieve deep carbon reductions



Finally, while this study identifies a number of promising pathways towards Xcel's long-term carbon goals, the cost of achieving carbon reductions remains highly uncertain and subject to impacts of factors beyond the company's control. Even in the scenario that this study identifies as a least-cost plan—one that combined nuclear relicensing, accelerated coal retirements, and investments in

© 2019 Energy and Environmental Economics, Inc.

renewables, storage, efficiency, and gas to meet long-term goals—the potential costs calculated at the study's endpoint in 2045 spans a broad range from 150% above to 125% below the costs under Base Case assumptions. The largest potential sources of risk identified in this study result from uncertainty on the future cost of new renewable and storage resources and the uncertainty of how the changing generation mix in the broader MISO system will impact Xcel's opportunities to manage costs through market transactions. The exposure of Xcel's portfolio to such uncertainty and the associated risks underscores the importance of constant vigilance and responsiveness to rapidly changing market conditions.

1 Introduction

1.1 Study Motivation

Across the United States, the electricity sector is in a rapid state of transition, driven by multiple factors:

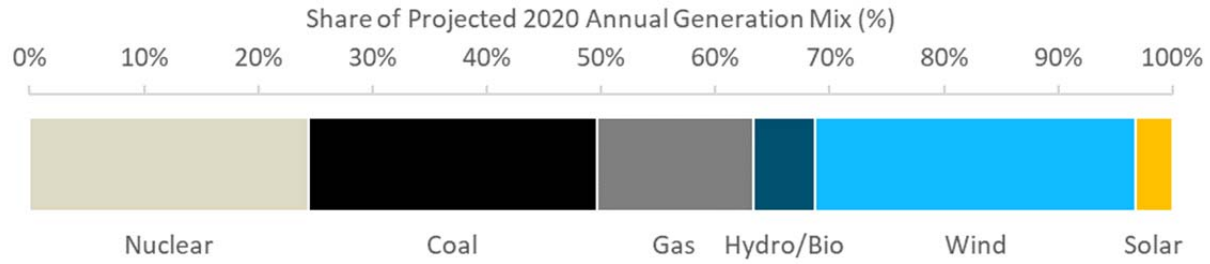
- An increasing preference for "clean" energy resources and interest in decarbonization of electricity supply at the state, utility, and customer levels;
- Significant realized cost reductions of renewable resources such as wind and solar, coupled with the emergence of new technologies such as battery storage; and
- Aging generation infrastructure leading to plant retirements and a corresponding need for investment in new generation resources.

These trends, and the elevated levels of investment in new renewable generation they have prompted throughout the country in the past decade, are likely to continue.

Since 2005, Xcel Energy's Upper Midwest system, which serves customers in Minnesota and four neighboring states, has made significant progress toward decarbonizing its energy supply. The Company's conversion of its High Bridge and Riverside coal plants, achievement of energy efficiency consistent with state standards, and investment in a total of over 3,000 MW of wind generation have led to a collective shift towards carbon-free generation resources, which are expected to represent approximately 60% of the Upper Midwest system's generation mix by 2020. The expected annual generation mix for the Upper Midwest system in 2020 is shown in Figure 1-1.

© 2019 Energy and Environmental Economics, Inc.

Figure 1-1. Projected annual generation mix in 2020

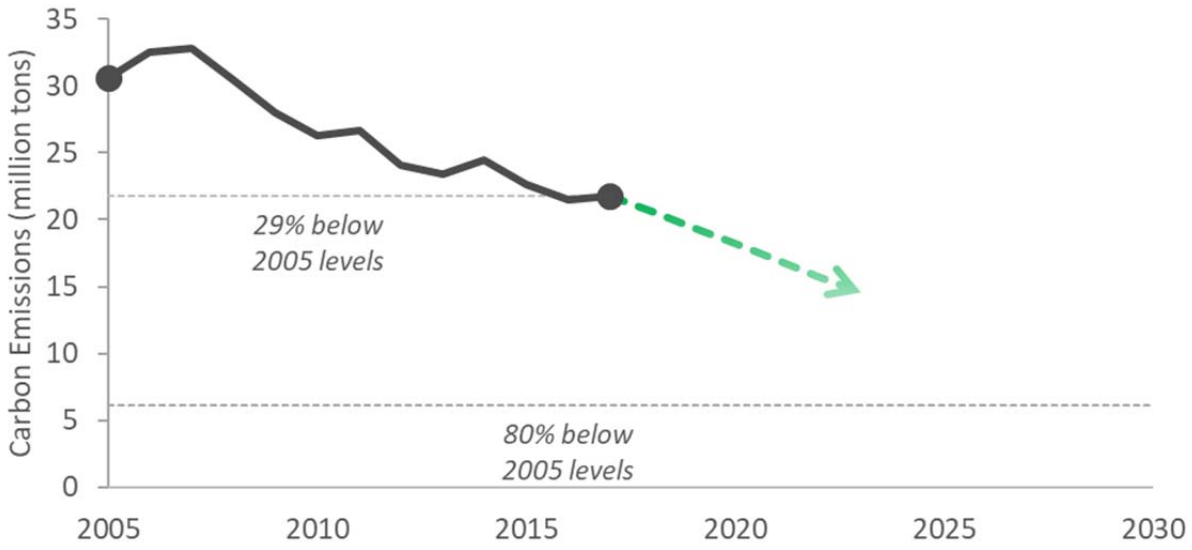


This shift has enabled significant carbon reductions in the Upper Midwest portfolio, whose 2017 emissions were roughly 30% below a 2005 benchmark level. Xcel also recently established notable forward-looking goals that imply significant continued effort in this area over the long term:

- Xcel's 2015 Upper Midwest Integrated Resource Plan established plans to retire two coal plants and meet 60% of customer loads with carbon-free resources by 2030; and
- In December 2018, Xcel announced a company-wide goal to reduce emissions by 80% by 2030 and to be 100% carbon-free by 2050, a first-of-its-kind target among U.S. utilities.

Thus, while the greenhouse gas emissions attributed to the Upper Midwest portfolio as of 2017 were roughly 30% below 2005 levels, significant additional reductions will be needed to meet the Company's long-term goals (see Figure 1-2).

Figure 1-2. Historical carbon emissions attributed to Xcel's Upper Midwest portfolio and a pathway towards long-term goals



Achieving these ambitious goals will require careful and strategic approaches to planning, procurement, and utility operations. While low-cost wind, solar and energy storage resources will make up the bulk of investments needed to meet Xcel's goals, additional capabilities will be needed to supplement these resources whose availability depends on uncontrollable meteorological phenomena. Balancing load and generation instantaneously and ensuring resource adequacy under all conditions (e.g., during periods of high load and low wind and solar output) requires an evolution in today's operational and planning practices. Designing a low-cost resource portfolio that simultaneously meets future reliability standards and clean energy objectives has become one of the principal long-term planning challenges for utilities today.

Within its current integrated resource planning cycle, whose analytical horizon stretches through 2034, Xcel's Upper Midwest system faces several significant questions that will establish a path to meeting long-term emissions goals. Among the key questions are: (1) how to manage retirement of aging coal

© 2019 Energy and Environmental Economics, Inc.

generators; (2) whether to seek extensions for nuclear plants whose current licenses expire shortly after 2030; (3) what level of investment in renewables, storage, and efficiency will be needed to meet greenhouse gas reduction targets; and (4) the extent to which investment in new gas resources will be needed for reliability purposes.

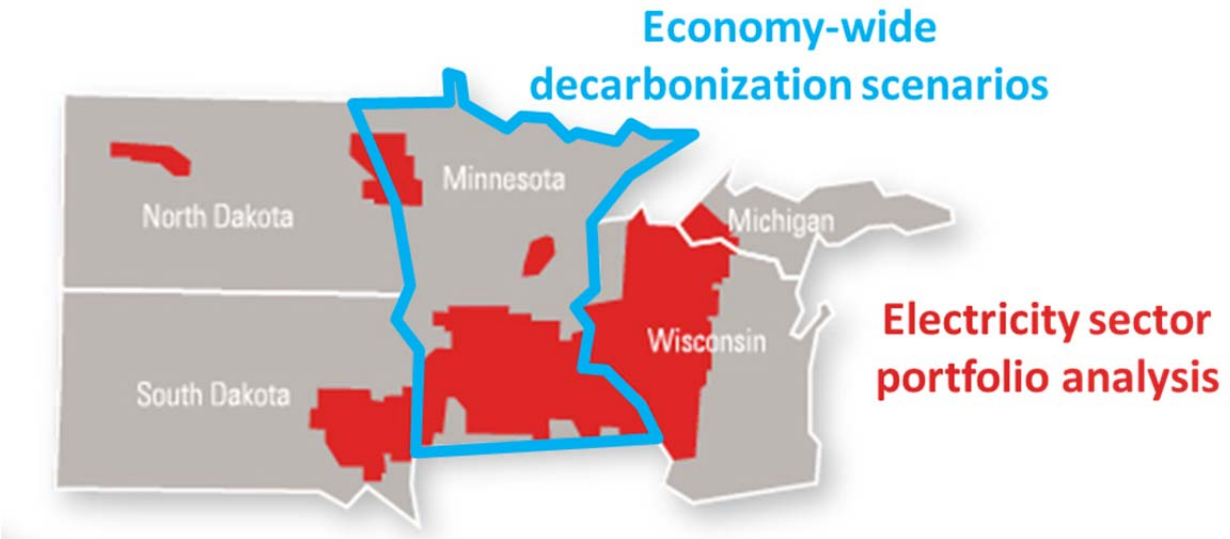
Both to inform its own strategic decision-making and to inform and engage stakeholders, Xcel commissioned two studies to provide an independent, unbiased, third-party perspective on these and related issues:

(1) An economy-wide analysis of deep decarbonization pathways for the State of Minnesota that establishes a vision for how the state could reduce carbon emissions 80% below 2005 levels by 2050; and

(2) An electricity portfolio optimization analysis that identifies a range of strategies Xcel could implement to meet near-term goals and align with long-term goals.

While the geographic scopes of these studies differ (see Figure 1-3.), they complement one another by creating general blueprints for decarbonizing electricity and the broader economy; in doing so, they highlight the central role of the electric utility in meeting long-term climate objectives. Together, these two studies supplement Xcel's own IRP analysis by providing an alternative and independent perspective that address the challenges facing Xcel's Upper Midwest system.

Figure 1-3. Overlapping geographic scopes of E3's two studies



1.2 Lessons from Pathways Analysis

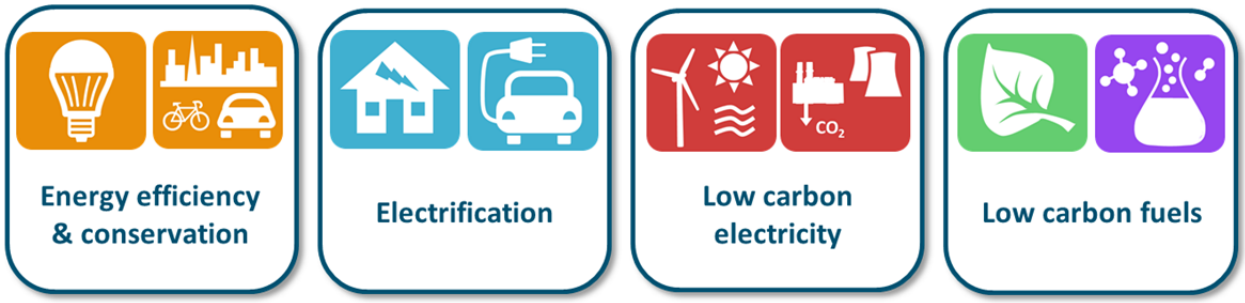
E3's "Minnesota Decarbonization Analysis," an economy-wide study of decarbonization for the state, contributes to a growing body of literature that explores the landscape of what is needed to reach deep levels of decarbonization, typically 80% reductions below a baseline level by 2050. These studies, conducted by E3 and others, have generally converged on a consensus view that four foundational "pillars" are necessary to achieve such significant reductions across the economy:

- Deployment of ambitious levels of **energy efficiency & conservation** beyond levels of historical achievement;
- **Electrification of end uses** traditionally fueled by fossil fuels, including vehicles, space and water heating, and industrial processes;

© 2019 Energy and Environmental Economics, Inc.

- Production of **low-carbon electricity** to supply clean energy to both existing and newly electrified loads; and
- Use of **low-carbon fuels**—for instance, biofuels, synthetic gas, and/or hydrogen—to supply energy to end uses that continue to rely on liquid and/or gaseous fuels.

Figure 1-4. Four pillars of deep decarbonization



These pillars highlight the central role of the electric sector in decarbonization: significantly reducing economy-wide greenhouse gas emissions requires the electric sector to decarbonize generation while supplying clean energy to new loads as more fossil-fueled end uses convert to electricity.

A number of the key findings from E3's decarbonization study for the state of Minnesota expand upon the necessity and role of these four pillars and further underscore the importance of decarbonizing electricity supply while minimizing costs to the extent possible:

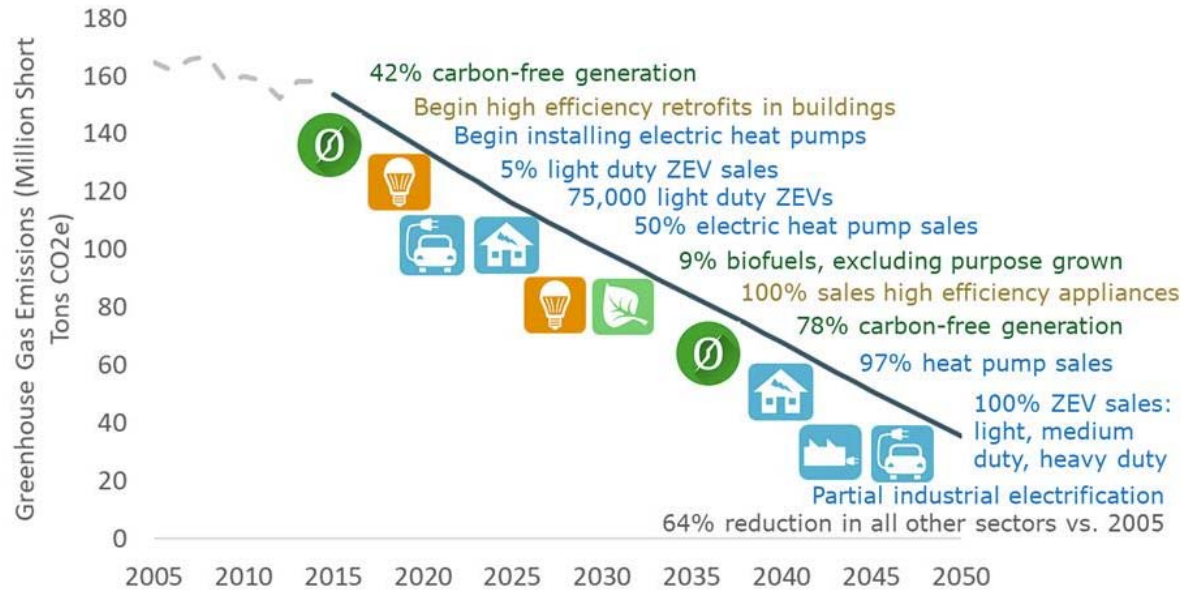
- **Electrification and zero-carbon electricity are necessary (but not sufficient) to reach statewide goals.** The analysis demonstrates how increased reliance on low-carbon electricity enables emission reductions by avoiding direct combustion of fossil fuels in households, businesses, and vehicles across a number of scenarios.
- **Buildings and transportation have significant potential to drive load growth, especially after 2025.** The analysis also highlights the significant potential for adoption of new electric appliances and vehicles, and the potential impact on total electricity requirements for Minnesota utilities. Transportation and building electrification drive electric load growth,

especially after 2030, particularly in a future with constraints on bioenergy. Electrification of space heating has a particularly large impact on both total load (MWh) and peak demand (MW).

+ **Reasonable electric rates and low costs for new electric devices are essential for electrification.** The levels of electrification modeled in buildings and transportation are dependent on consumer adoption, which will benefit from reductions in capital costs and reasonable electric rates, even as the electric grid continues to decarbonize.

The economy-wide emissions trajectory towards deep decarbonization, along with the key transformations that enable these reductions, are shown in Figure 1-5.

Figure 1-5. Emissions and infrastructure transformations in the "High Electrification" scenario from E3's economy-wide pathways analysis



© 2019 Energy and Environmental Economics, Inc.

1.3 Study Overview

As a complement to the economy-wide pathways study, this study focuses on how to decarbonize electricity supply in the Upper Midwest. In doing so, it addresses several key questions implied by Xcel's aggressive targets:

- What is the composition of the Upper Midwest system portfolio—and what are its corresponding greenhouse gas emissions—under a "Reference Case" scenario reflecting a business-as-usual, least-cost approach to meeting future energy and capacity needs?
- What are Xcel's options—and what are the corresponding costs—for achieving steep emission reductions consistent with near- and long-term goals, and how do these compare to the Reference Case?
- What are the reliability implications of relying heavily on renewable and storage resources? Could an electric system achieve 100% emissions reductions using only today's commercially available technologies while maintaining reliability?

To answer these questions, this study uses scenario analysis to design and characterize a range of different portfolios that each achieve aggressive levels of decarbonization relative to a Reference Case. The portfolios are constructed from different assumptions about potential coal and nuclear plant retirements and future investments in natural gas resources, which in turn determine the quantity and timing of future renewables and storage additions and investments in demand-side resources needed to meet long-term carbon reduction goals. The analysis spans the years 2020 through 2045, extending beyond the traditional IRP planning horizon in an effort to provide additional information on the implications of Xcel's long-term goals; however, the analysis stops short of attempting to "solve" for how Xcel Energy might meet its 2050 goals in recognition of the likely but unpredictable role that future technological innovation will play in allowing Xcel to achieve the final increments of decarbonization. Figure 1-6 shows the building blocks this study used to construct alternative scenarios and develop portfolios.

Figure 1-6. Building blocks for scenario development.

Resource	Scenario Options			
Nuclear	Retire upon license expiry	Relicense Monticello only	Relicense both nuclear plants	Retire Prairie Island by 2030
Coal	Retire all plants at end of useful life	Retire AS King by 2030	Retire all coal by 2030	
Gas	Allow investment in new gas	Limit new gas additions to Sherco CC	Prohibit all new gas investment	
Wind	Add new wind to meet energy, capacity, and clean energy goals			
Solar	Add new solar to meet energy, capacity, and clean energy goals			
Storage	Add new storage to meet capacity & flexibility needs			
DR	Add new DR to meet capacity needs			
Efficiency	Deploy energy efficiency to meet energy, capacity & clean energy needs			

The study relies primarily on two complementary models developed by E3, both designed to investigate the implications of heavy reliance on renewables and storage:

+ **E3's Renewable Energy Capacity (RECAP) model**, a loss-of-load-probability model that provides a detailed and statistically robust perspective on the reliability of electric systems with conventional, renewable, storage, and demand-side resources; and
+ **E3's Renewable Energy Solutions (RESOLVE) model**, a capacity expansion model that uses optimization techniques to identify a least-cost portfolio of resource investments to meet future reliability and clean energy objectives.

© 2019 Energy and Environmental Economics, Inc.

These tools complement one another and jointly provide a strong foundation for analyzing and understanding the implications of a long-term transition towards low-carbon and carbon-free resource portfolios. In this study, RECAP provides a rigorous, data-driven perspective on the future reliability needs of the Xcel portfolio and the ability of wind, solar, and storage to meet those needs; RESOLVE builds on this analysis to design least-cost portfolios that achieve reliability objectives while meeting clean energy goals, balancing large quantities of variable resources, and minimizing costs.

1.4 Relationship to Xcel's Analysis

By design, the scope of analysis conducted in this study overlaps considerably with the internal analysis conducted by Xcel Energy in the development of its preferred plan as filed in its Integrated Resource Plan. Wherever possible, this study relies on the same numerical inputs and assumptions as used by Xcel's IRP team, supplemented by publicly available data sources where necessary. This approach was chosen to ensure that the results of Xcel's internal analysis align with the rigorous, industry-standard approaches.

The methods employed in this study, which E3 has used across a wide range of North American jurisdictions, are generally consistent with those used in the Strategist model used by Xcel Energy's IRP team. However, E3's RESOLVE model and Strategist do deviate from one another in several key methodological areas; the key differences between the two are discussed further in Section 2.1.2.

The inputs and assumptions used in this study provided by Xcel Energy are consistent with public data sources that E3 has used in other studies. To that effect, the key findings of this study are E3's conclusions, and do not directly represent conclusions or future commitments of Xcel Energy. This study makes no recommendations for formal preferred plan for the company, but does offer a supplemental perspective for the Commission and stakeholders to consult in evaluating Xcel's proposed preferred plan.

1.5 Report Contents

The remainder of this report is organized as follows:

- **Section 2** describes the scenarios and modeling approach used in the study;
- **Section 3** describes the key modeling inputs and assumptions that shape the analysis;
- **Section 4** presents the results of the reliability analysis;
- **Section 5** presents the results of the portfolio analysis; and
- **Section 6** discusses the key conclusions reached from this study.

Additional details on the study's methods, data inputs, and results can be found in the technical appendices:

- **Appendix A** describes the methodology of RECAP;
- **Appendix B** describes the methodology of RESOLVE;
- **Appendix C** provides additional detail on the development of study inputs; and
- **Appendix D** provides additional detail model results across the scenarios and sensitivities.

© 2019 Energy and Environmental Economics, Inc.

2 Modeling Methodology

2.1 Modeling Approach

This study relies upon two resource planning models developed by E3 and tailored towards analysis of electric systems at high penetrations of renewable generation to develop and analyze a range of scenarios to explore potential options for carbon reductions in the Upper Midwest system portfolio:

- **E3's Renewable Energy Capacity (RECAP) model**, a loss-of-load-probability model that provides a detailed and statistically robust perspective on electric systems that rely on a combination of conventional, renewable, storage, and demand-side resources; and
- **E3's Renewable Energy Solutions (RESOLVE) model**, a capacity expansion model that uses optimization techniques to identify a least-cost portfolio of resource investments to meet future reliability and clean energy objectives.

These two tools complement one another in their application, together providing a strong foundation with which to analyze and understand implications of long-term transitions towards low carbon and carbon-free portfolios. As illustrated in Figure 2-1, these models are used together: the study first uses RECAP to characterize potential contributions of different technologies towards system resource adequacy needs; this, in turn, serves as an input to RESOLVE, to ensure that the least-cost portfolio outcome meets reliability goals.

Figure 2-1. Two-phase approach used in this study

2.1.1 RELIABILITY ANALYSIS

2.1.1.1 Scope of Analysis

One of today's principal concerns among utilities and system operators alike is the preservation of resource adequacy in electric systems that are rapidly transitioning towards greater reliance on variable (e.g. wind and solar) and use-limited resources (e.g. storage, demand response) and away from traditional sources of firm, dispatchable capacity (e.g. nuclear, coal, and gas). Many jurisdictions—including the Midcontinent Independent System Operator (MISO), of which Xcel's Upper Midwest system is a member—have transitioned towards the use of "effective load carrying capability" (ELCC)—a rigorous measure of capacity value derived through loss-of-load-probability analysis—to measure the contributions of wind and solar towards resource adequacy needs, and there is growing consensus within the industry that such techniques will eventually be needed for storage at higher levels of deployment as well. This study's first phase begins with a detailed examination of the potential contributions of such resources towards Xcel Energy's future resource adequacy needs.

As a member of MISO, Xcel Energy is obligated to meet an annual planning reserve margin (PRM) requirement by either self-supplying capacity or purchasing it directly through the MISO market. The accounting conventions through which capacity from resources is accredited towards this requirement are administered by MISO; the contribution of each type of generation resource depends on its

© 2019 Energy and Environmental Economics, Inc.

performance characteristics and availability to produce power during the most constrained periods of the year:

- Traditional dispatchable resources are accredited at their full firm capacity;[1]
- Wind and solar resources are assigned capacity value based on ELCC studies conducted by MISO (currently, 16% and 50%, respectively, but subject to periodic updates with changes to the system); and
- Energy storage with four hours of duration is assigned full capacity value.

Projecting how capacity accreditation for variable and use-limited resources will change in MISO over the twenty-five year horizon of this analysis—which would require forecasting changes in its load and resource mix and a corresponding loss-of-load-probability analysis across the full RTO footprint—is beyond the scope of this type of study.

Rather than undertaking such an exercise, this study relies on a simplifying convention for variable and use-limited resources that considers only the capacity value that those resources provide to Xcel's Upper Midwest system. This is accomplished by developing a model of the Upper Midwest loads and resource portfolio in RECAP and using the model to derive curves of the "effective load carrying capability" (ELCC) as a function of penetration for wind, solar, storage, and demand response. Through the development of these ELCC curves that reflect the capacity value of variable and use-limited resources, RECAP is used to derive inputs for a resource adequacy requirement to be used in the optimization process. The conventions used in this study are shown in Table 2-1, where they are contrasted against the actual obligations Xcel Energy faces as a MISO member.

[1] Traditional dispatchable resources are accredited based on their UCAP or unforced capacity value.

Table 2-1. Conventions used for resource adequacy accounting in this study compared to Xcel's obligation as a MISO member

Assumption	Xcel's MISO Obligation	RESOLVE Portfolio Analysis
Planning reserve margin requirement	3% above Xcel non-coincident peak demand	
Thermal/dispatchable plants	Plant-specific firm capacity rating	
Wind & solar ELCC	MISO accredited ELCC (currently 50% for solar and 16% for wind)	RECAP ELCC curves for Xcel Energy system
Energy storage ELCC	Full capacity accreditation for storage with >4 hour duration	RECAP ELCC curve for Xcel Energy system

Notably, this study preserves Xcel's PRM requirement of 3% above its noncoincident peak, which inherently captures a large portion of the reliability benefits that Xcel Energy realizes through its MISO membership: a lower planning reserve margin requirement due to the diversity benefit of participation in a capacity sharing pool. The important distinction between this study's approach and Xcel's obligation is the use of Xcel-specific ELCC curves for variable and use-limited resources, which ensures that each portfolio of resources is sufficient to meet Xcel's own resource adequacy needs while still relying on the diversity benefit afforded to it through MISO membership.

The reliability analysis conducted in the first phase serves a secondary purpose as well: it provides an opportunity to examine what infrastructure investments would be needed to achieve a reliable portfolio that relies solely on carbon-free, non-combustion resources (primarily nuclear, wind, solar, and storage). In addition to deriving ELCC curves for a variety of resources, this study uses RECAP to design two portfolios that rely exclusively on carbon-free resources to serve load by 2045: one that includes Xcel's existing nuclear plants and another that relies only on wind, solar, and storage to meet reliability needs. These two portfolios are compared against today's system to illustrate the magnitude of investment needed to reach a fully carbon-free portfolio without any fossil combustion.

© 2019 Energy and Environmental Economics, Inc.

2.1.1.2 Methodology

The reliability analysis conducted in the first phase of this analysis is completed using RECAP, a loss-of-load-probability model developed by E3 and specifically tailored to answer questions on resource adequacy in systems heavily reliant on variable and use-limited resources. Its rigor lies in its simulation of the capability of a portfolio of generating resources to meet loads across a wide range of potential conditions, using a Monte Carlo approach to simulate thousands of potential years of plausible conditions on the system. RECAP incorporates features such as:

- Use of decades of historical weather data to develop synthetic hourly load shapes reflective of long-term patterns of load variability;
- Stochastic internal logic to produce chronological strips of load and corresponding renewable profiles that preserve correlations observed in a limited set of weather-matched chronological data;
- Stochastic simulation of forced outages based on expectations for mean time to failure and mean time to repair for dispatchable generators; and
- Time-sequential dispatch logic that allows the model to track state of charge and/or other constraints on use-limited resources (e.g. energy storage, demand response) that may limit their availability.

Through this robust simulation of load and generator availability, RECAP can be used to analyze whether an electric system's generation portfolio meets a specified reliability standard (most commonly, a standard of no more than "one day in ten years" of lost load). In evaluating resource adequacy, RECAP also produces a number of metrics directly useful to utilities in planning and procurement, including (1) a target planning reserve margin; (2) a variety of statistics for a given electricity system to characterize the size, frequency, and duration of reliability events; and (3) ELCC values for different types of resources on the system. Additional detail on the methodology of the RECAP model is presented in Appendix A.

This study relies on RECAP's simulation capabilities primarily to produce ELCC curves that serve as a key input into RESOLVE. The portfolio analysis relies on a PRM requirement to design a portfolio that meets reliability needs, and so RECAP is used to determine the extent to which variable and use-limited resources can contribute to meeting that requirement. RECAP is used to derive ELCC "curves" that capture how the capacity value of each resource changes as a function of penetration that in turn serve as inputs to a portfolio optimization process that uses this information to determine the appropriate level upon which to rely upon these resources to meet resource adequacy needs.

2.1.2 PORTFOLIO ANALYSIS

2.1.2.1 Scope of Analysis

The purpose of the second phase of this analysis is to design and evaluate a range of portfolios that simultaneously meet Xcel's reliability standards and ambitions for greenhouse gas reductions while also mitigating costs to its ratepayers. Designing portfolios to meet multiple objectives is a complex multidimensional problem that, in the context of increasing reliance on variable and use-limited resources, presents a new challenge to resource planners. In developing future resource plans, utilities must consider a broader range of available resource options (e.g. thermal generators, renewables, storage, demand-side resources), each with unique characteristics in their potential impacts on the system and interactive effects with other resources. Developing a least-cost plan to meet multiple objectives requires consideration of a range of different questions:

- What are the fixed costs associated with a specific portfolio of new resources due to investments and operations and maintenance?
- To what extent will a portfolio of resources meet resource adequacy needs, considering both the declining ELCC of different resource types and the interactive effects between technologies?
- How will a portfolio affect the operations of the electric system across the year, and thereby the cost and associated greenhouse gas intensity to meet utility load?

© 2019 Energy and Environmental Economics, Inc.

- How could retirement of existing plants either facilitate or inhibit the achievement of utility goals?

This second phase uses optimization modeling techniques to answer these questions through the development of a range of portfolios to meet Xcel's reliability standards while achieving substantial levels of carbon reduction.

2.1.2.2 Methodology

In this phase, this study uses E3's RESOLVE model to optimize future generation portfolios. RESOLVE is a capacity expansion model that uses linear programming to identify optimal long-term generation and transmission investments in an electric system, subject to reliability, technical, and policy constraints. Designed specifically to address the capacity expansion questions for systems seeking to integrate large quantities of variable resources, RESOLVE layers capacity expansion logic on top of a reduced-form production cost model to determine the least-cost investment plan, accounting for both the up-front capital costs of new resources and the variable costs to operate the grid reliably over time. In an environment in which most new investments in the electric system have fixed costs significantly larger than their variable operating costs, this type of model provides a strong foundation to identify potential investment benefits associated with alternative scenarios.

RESOLVE's optimization capabilities allow it to select from among a wide range of potential new resources. The full range of resource options considered by RESOLVE in this study is shown in Table 2-2 below.

Figure 2-2. RESOLVE modeling methodology

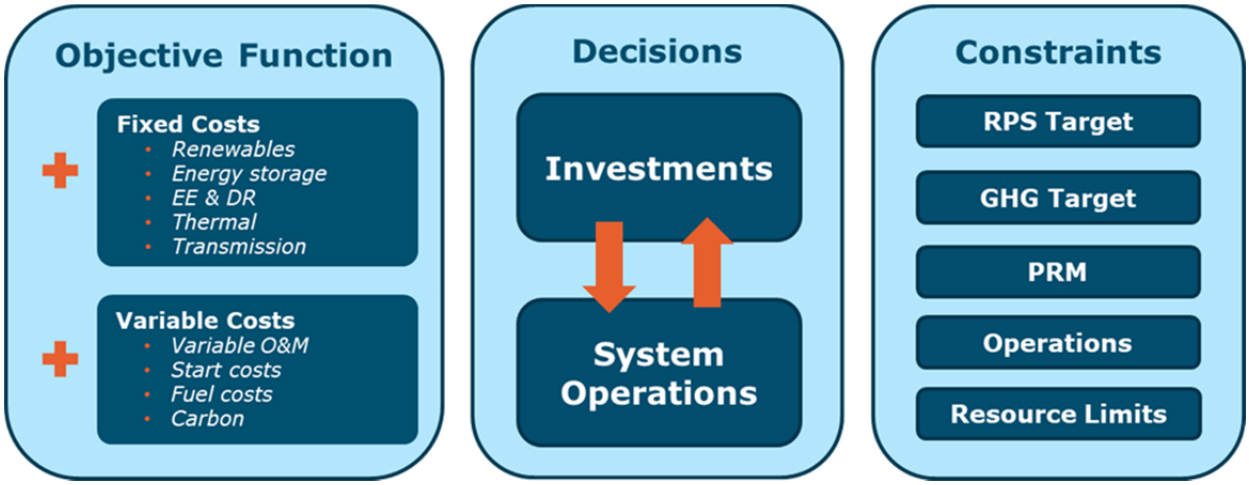


Table 2-2. Resource options considered in RESOLVE

Resource Option	Examples of Available Options	Capabilities
Natural Gas Generation	• Simple cycle gas turbines • Combined cycle gas turbines	• Dispatches economically based on heat rate, subject to operational constraints • Contributes to ramping & reserve needs • Provides large capacity value
Renewable Generation	• Solar PV • Wind	• Curtailable when needed to balance load • Provides limited capacity value based on ELCC
Energy Storage	• Batteries (4 hr)	• Balances hourly net load variability • Contributes to ramping & reserve needs • Provides limited capacity value based on ELCC
Energy Efficiency	• HVAC • Lighting	• Reduces demand throughout the year • Reduces resources need for reliability
Demand Response	• Interruptible tariff • Critical Peak Pricing	• Provides limited capacity value based on ELCC

To identify optimal investments in the electric sector, maintaining a robust representation of prospective resources' impact on system operations is fundamental to ensuring that the value each

© 2019 Energy and Environmental Economics, Inc.

resource provides to the system is captured accurately. At the same time, the addition of investment decisions across multiple periods to a traditional unit commitment problem increases its computational complexity significantly. RESOLVE's simulation of operations has therefore been carefully designed to simplify a traditional unit commitment problem where possible while maintaining a level of detail sufficient to provide a reasonable valuation of potential new resources. The key attributes of RESOLVE's operational simulation are enumerated below:

- **Hourly chronological simulation of operations:** RESOLVE's representation of system operations uses an hourly resolution to capture the intraday variability of load and renewable generation. This level of resolution is necessary in a planning-level study to capture the intermittency of potential new wind and solar resources, which are not available at all times of day to meet demand and must be supplemented with other resources.
- **Planning reserve margin requirement:** When making investment decisions, RESOLVE requires the portfolio to include enough firm capacity to meet coincident system peak plus additional 3% of planning reserve margin (PRM) requirement. This value is Xcel's contribution as a utility to the overall MISO planning reserve margin of 8.4%. The contribution of each resource type towards this requirement depends on its attributes and varies by type: for instance, variable renewables are discounted compared to thermal generators because of limitations on their availability to produce energy during peak hours.
- **Greenhouse gas cap:** RESOLVE also allows users to specify and enforce a greenhouse gas constraint on the resource portfolio for a region. As the name suggests, the emission cap requires that annual emission generated in the entire system to be less than or equal to the designed maximum emission cap. As it designs future portfolios, RESOLVE chooses both (1) how to dispatch new and existing resources to meet the goal (e.g. displacing output from existing coal plants with increased natural gas generation) and (2) what additional investments are needed to further reduce carbon in the system.

Additional detail on the methodology of the RESOLVE model is included in Appendix B.

2.1.2.3 Comparison to Strategist

The Xcel Upper Midwest team uses the Strategist model for answering questions on capacity expansion and planning optimization. Although in the same family of model as E3's RESOLVE model, there are key differences in how investments are evaluated in both models. These differences are highlighted in Table 2-3. below.

Table 2-3. Key differences between RESOLVE & Strategist

Model Feature	Strategist	RESOLVE
System Operations	Load duration curve heuristic	Chronological hourly dispatch with simplified unit commitment
Day Sampling	Representative weeks for each month	Smart sample of ~40 representative days
Market Interactions	Purchases & sales determined based on exogenous wholesale price forecast	Market interactions simulated endogenously with representation of external loads & resources
Resource Adequacy	Planning reserve margin with deemed credits for each resource	Planning reserve margin with dynamically updating ELCC values for renewables

Some implications of these differences are highlighted below:

- Accurately capturing the impacts and operational value of resources like energy storage, for which simulation of chronological dispatch is important, is difficult in models that rely on load duration curve heuristics to approximate system operations—particularly as the penetrations of renewables and storage resources increase.
- The assumption that Xcel is a price taker in the MISO market, implicit in the use of static wholesale prices to represent the external market, may not fully capture the effects that large changes in Xcel's own portfolio could have on the market itself. As the portfolios of Xcel and other utilities within the MISO footprint shift away from fossil resources and towards higher levels of renewables, capturing the changing market dynamics and implications of Xcel's own decisions on the market itself will become an increasingly important link in resource planning.

© 2019 Energy and Environmental Economics, Inc.

+ Similarly, the application of static capacity credits for resources like wind, solar, and storage will not capture the necessary evolution of capacity accreditation to ensure reliability at higher levels of penetration. Future resource planning efforts should consider how the capacity contributions of various future investments will change as penetrations increase rather than assuming capacity accreditation in the future remains consistent with today's rules.

Each of these implications suggests a need for resource planning practices in general to evolve towards a more dynamic, anticipatory paradigm to allow prudent planning in spite of a rapidly transforming system.

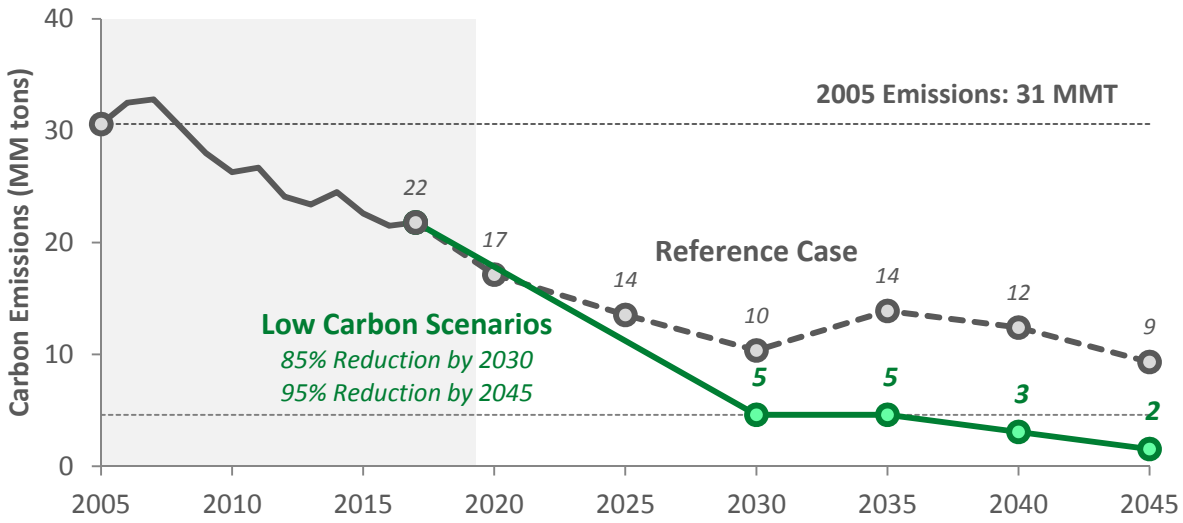
2.2 Scenarios & Sensitivities

2.2.1 OVERVIEW OF SCENARIOS

This study focuses on a suite of scenarios that examine the range of strategies Xcel could take to meet greenhouse gas reduction goals in the Upper Midwest system. Each of the scenarios and sensitivities, aside from the Reference Case, meet or surpass the carbon target shown in Figure 2-3; reaching an 85% reduction in carbon emissions by 2030 (beyond Xcel's actual 2030 target of an 80% reduction) and a 95% reduction in carbon emissions by 2045 (on track to meet Xcel's 2050 target of carbon neutrality).[2]

[2] The 2030 target modeled in this analysis is an assumption developed by E3 that reflects a plausible expectation that to achieve a company-wide goal of 80% carbon reductions by 2030 may require the Upper Midwest system to go beyond this target. This assumption (and the low carbon trajectory in its entirety) are not formally representative of carbon goals established by Xcel for its Upper Midwest system.

Figure 2-3. Future Upper Midwest carbon reduction pathway as modeled in this study compared to counterfactual Reference Case



The Reference Case modeled in this study is developed to provide a cost and emissions benchmark against which to compare each of the low carbon scenarios. It incorporates the following assumptions:

- **Achievement of existing RPS goals** associated with existing statutes—including a 30% RPS by 2020 for Xcel (as Minnesota's largest utility);
- **Planned new resources**, including over 2 GW of new renewable capacity by 2030, a new 835 MW combined cycle plant at the Sherco facility in 2027, and an additional 400 MW to Xcel's current DR program;
- **Announced retirement dates of existing coal plants**, including Sherco units 1, 2, and 3 (2026, 2023, and 2040), AS King (2037)
- **Retirement of nuclear plants at end of current licenses:** Monticello (2030), Prairie Island 1 and 2 (2033 and 2034)
- **Forecasted cost reductions** for new solar, wind, and storage technologies consistent with industry expectations.

© 2019 Energy and Environmental Economics, Inc.

This study compares 21 "low carbon" scenarios against this Reference Case. The scenarios, listed in Table 2-4, were broadly designed in several categories to investigate key questions:

- A set of **Coal Retirement Cases**, which informs the value of retiring various levels of Xcel's coal fleet (AS King and Sherco 1, 2, and 3) to meet the carbon reduction goals;
- A set of **New Gas Prohibition Cases**, which prohibits the construction of new gas generation (including or not including the new Sherco CCGT), forcing all future energy and capacity needs to be met by carbon-free resources; and
- A set of **Nuclear Relicensing Cases**, which investigates the value of keeping the existing carbon-free, firm capacity (Monticello and Prairie Island 1 and 2) online through 2045.

Table 2-4. Matrix of scenarios evaluated

ID	AS King	Sherco 3	Prairie Island	Monticello	New Gas?
0	**Planned ret**	**Planned ret**	**Not relicensed**	**Not relicensed**	**Yes**
1	Planned ret	Planned ret	Not relicensed	Not relicensed	Yes

2.2.2 SENSITIVITY ANALYSIS

The long-term scenario analysis conducted in this type of study relies on projections of future conditions that are inherently uncertain. Utilities have historically incorporated uncertainty in such factors as fuel price forecasts and load growth into their integrated resource planning analyses to account for this uncertainty. With the transition of the industry towards resources that consume less fuel but are more capital intensive, new sources of uncertainty become important considerations for resource planners—for instance, future anticipated cost reductions for resources like wind, solar, and battery storage. This study conducts sensitivity analyses on a number of such uncertainties to evaluate the robustness of the conclusions reached in this analysis. The list of sensitivities explored within this analysis is shown in Table 2-5. Inventory of sensitivities explored in analysis—while no means meant to represent a comprehensive analysis of all uncertainties faced by utilities, these represent a number of the key factors that should be considered in resource planning and decision-making. Sensitivities are not tested against all scenarios—instead, a subset of scenarios is selected for more detailed examination through sensitivities.

Table 2-5. Inventory of sensitivities explored in analysis

Sensitivity	Description
High/Low Gas Prices	Alternative projections of natural gas natural gas prices (+/- 50% adjustment to CAGR) that tests how future gas prices will impact cost of decarbonization.
High/Low Technology Costs	Alternative price projections for renewable & storage technologies that evaluates impact of future technology costs on cost of decarbonization.
Low Exports	Assumes Xcel cannot sell surplus generation into the MISO market beyond 2030, reflecting a bookend scenario for adverse market conditions in which demand for surplus power throughout MISO is limited
High Electrification Loads	Assumed loads increase by ~21 TWh by 2045 due to space & water heating electrification, as well as electric vehicle integration

3 Inputs & Assumptions

This study relies on a wide range of inputs and assumptions to populate the RESOLVE and RECAP models. Wherever possible, inputs and assumptions are aligned with those used directly by Xcel to prepare its own IRP filing for the Upper Midwest system; in some cases, data from publicly available information was used as a supplement to information provided by Xcel. The key categories of inputs and assumptions to E3's two portfolio analysis models are summarized in Table 3-1. Additional detail on each specific input is included in subsequent sections.

Table 3-1. Summary of some key inputs and assumptions for RESOLVE and RECAP

Input Category	Used in Model	Description
Demand forecast	RESOLVE, RECAP	Annual demand and peak forecast for the Upper Midwest system
Existing resources	RESOLVE, RECAP	Capacity, commission dates, retirement dates and operating characteristics for all existing and planned resources within the Xcel Upper Midwest system
New resources	RESOLVE, RECAP	Costs and performance for candidate resources considered in the portfolio optimization
Hourly profiles	RESOLVE, RECAP	Hourly profiles for all the components of demand; hourly generation profiles for solar and wind resources; hourly profiles for all other chronological hourly dispatch resources like EE
Fuel price forecasts	RESOLVE	Fuel price forecast data for all thermal resources
MISO market representation	RESOLVE	Load and resource assumptions for other external MISO zones connected to Xcel's Upper Midwest service territory

© 2019 Energy and Environmental Economics, Inc.

3.1 Demand Forecast

3.1.1 BASE CASE

The demand forecast used in this study captures expected future changes in electricity demand within Xcel's Upper Midwest service territory. The demand forecast accounts for expected growth in loads due to future economic and demographic trends but does not account for the future impacts of Xcel's energy efficiency programs; these efficiency programs are represented instead in this analysis explicitly as a supply-side resource with a variable profile. The assumed demand forecast assumptions, shown in Table 3-2., align with Xcel's Upper Midwest IRP modeling assumptions.

Table 3-2. Xcel Base Case demand forecast

Category	Historical 2018	Forecast 2020	2025	2030	2035	2040	2045	CAGR '18-'45
Retail Sales (GWh)	44,348	45,129	46,589	49,704	51,577	53,007	53,921	0.7%
Peak Demand (MW)	9,241	9,399	9,927	10,628	11,426	11,956	12,420	1.1%

Retail sales represent the demand for electricity at the customer meter and are grossed up for transmission and distribution losses (7%) when simulating the operations of the bulk electric power system; peak demand is reported at the wholesale level and so already accounts for the impact of transmission & distribution losses.

3.1.2 HIGH ELECTRIFICATION SENSITIVITY

The results of the economy-wide deep decarbonization pathways analysis discussed in Section 1.1 suggests that achievement of deep decarbonization targets across the economy requires electrification of multiple end uses; particularly transportation, space heating, and water heating. To develop a High Electrification sensitivity for this study, E3 used projections of future electric sector load from the "High

Electrification" scenario in E3's pathways study, downscaled to represent the Upper Midwest service territory. This sensitivity explores the impact on the Xcel system of increased demand due to space and water heating electrification and increased electric vehicle integration. Table 3-3 shows the impacts of incremental electrification on Xcel's annual energy demand in this High Electrification sensitivity.

Table 3-3. Buildup of retail sales forecast used in High Electrification sensitivity

Category	Historical 2018	Forecast 2020	2025	2030	2035	2040	2045	CAGR '18-'45
Base Case	**44,348**	**45,129**	**46,589**	**49,704**	**51,577**	**53,007**	**53,921**	0.7%
Space Heating	-80	-87	-28	+315	+1,772	+4,030	+6,386	
Water Heating	+87	+145	+251	+160	+317	+713	+1,083	
Electric Vehicles	+38	+79	+338	+1,559	+4,733	+9,369	+13,639	
High Electrification	**44,393**	**45,266**	**47,149**	**51,738**	**58,400**	**67,118**	**75,030**	**2.0%**

Before 2030, the space heating component causes a decrease in total retail sales because the amount of electrified spacing heating is not yet enough to overcome the benefits from the increased efficiency. By 2045, all three components cause a 39% increase in annual retail sales relative to the Base Case. Through the modeling period, electric vehicle integration contributes the largest increase in retail sales on an annual basis.

The corresponding impact on peak demand from the high level of electrification is more significant (see Table 3-4), nearly doubling over the analysis horizon through 2045. The major driver of the significant increase in peak is the electrification of end use heating loads, which, beginning in the early 2030s, cause Xcel to shift from a summer to a winter peak. Thereafter, the magnitude of the winter peak rises dramatically with increased deployment of heat pumps and other newly electrified loads.

© 2019 Energy and Environmental Economics, Inc.

Table 3-4. Buildup of peak demand forecast used in High Electrification Sensitivity

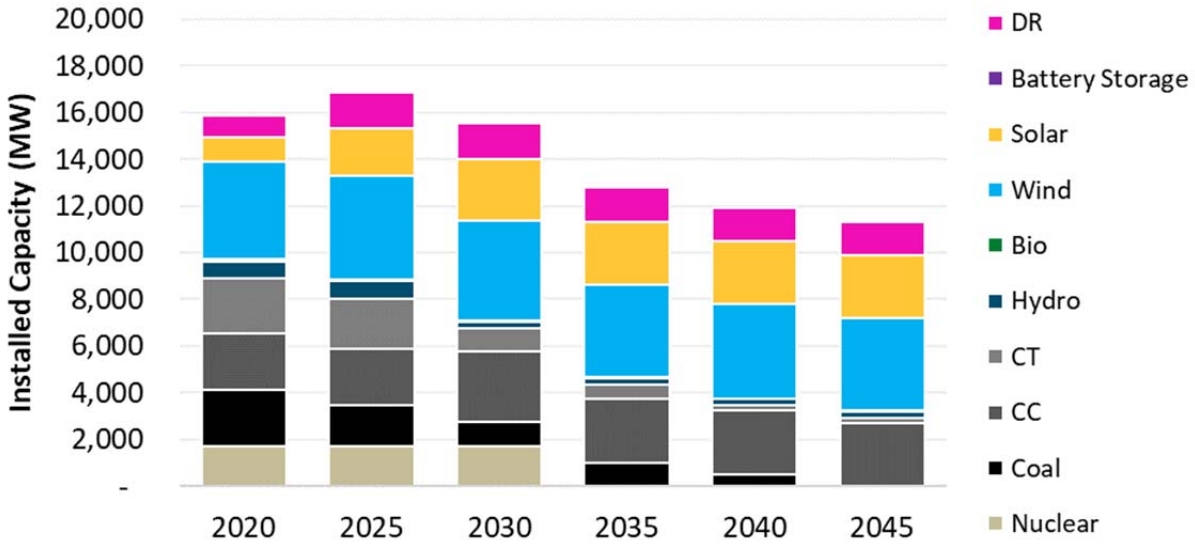
Category	Historical 2018	Forecast 2020	2025	2030	2035	2040	2045	CAGR '18-'45
Base Case	9,241	9,399	9,927	10,628	11,426	11,956	12,420	**1.1%**
Incremental Load From Electrification	8	+7	+77	+207	+855	+5,347	+10,369	
High Electrification	**9,249**	**9,406**	**10,004**	**10,835**	**12,281**	**17,302**	**22,789**	**3.4%**

3.2 Existing Resource Portfolio

The primary source for data on existing and planned generation is Xcel IRP modeling assumptions. The composition of Xcel's existing fleet is shown in Figure 3-1, reflecting Xcel's commitments and plans established by prior IRP. Key changes to the system captured in Figure 3-1 include:

- **Planned new resources**, including nearly 2 GW of new renewable capacity by 2030, a new 835 MW combined cycle plant at the Sherco facility in 2027, and an additional 400 MW to Xcel's current DR program from 2023;
- **Announced retirement dates of existing coal plants**, including Sherco units 1, 2, and 3 (2026, 2023, and 2040), AS King (2037); and
- **Retirement of nuclear plants at end of current licenses:** Monticello (2030), Prairie Island 1 and 2 (2033 and 2034).

Figure 3-1. Existing resource assumptions for Xcel portfolio over time



3.2.1 NUCLEAR

Xcel's current generation portfolio includes three nuclear units:

- Monticello (646 MW), whose license expires in 2031;
- Prairie Island 1 (546 MW), whose license expires in 2033; and
- Prairie Island 2 (546 MW), whose license expires in 2034.

Together, these baseload carbon-free resources are capable of producing roughly 14,000 GWh on an annual basis, enough to meet approximately 30% of Xcel's annual energy needs.

This study examines multiple options for retirement and relicensing of these existing nuclear units across different scenarios; these assumptions are summarized in Table 3-5. The Reference Case assumes that all units retire upon the expiry of their existing licenses, which results in a significant need for new investment to meet energy and capacity needs in the early 2030s; alternative scenarios examine the

© 2019 Energy and Environmental Economics, Inc.

potential effects of extending the licenses at one or both facilities through the analysis horizon, testing the impact of retaining baseload carbon-free generation within the context of Xcel's future carbon reduction goals.

Table 3-5. Xcel nuclear plant assumptions

Reference Assumptions			
Plant	**Capacity (MW)**	**Retirement**	**Notes**
Monticello	646	2030	Plant life extended by 20 years in scenarios 10-15
Prairie Island 1	546	2033	Plant life extended by 20 years in scenarios 13-15
Prairie Island 2	546	2034	Plant life extended by 20 years in scenarios 13-15

Each nuclear plant is modeled as a baseload, must-run unit, available to produce energy at full capacity throughout the year but for several periods of assumed extended outage for maintenance and refueling.

3.2.2 COAL

Xcel currently owns four coal plants operating in the Upper Midwest service territory:

- Allan S King (511 MW), whose planned retirement date is in 2037;
- Sherco 1 (680 MW), whose planned retirement date is in 2026;
- Sherco 2 (682 MW), whose planned retirement date is in 2023; and
- Sherco 3 (517 MW), whose planned retirement date is in 2040.

This study examines multiple options for retirement of the two existing coal units with retirement dates beyond 2030; these assumptions are summarized in Table 3-6.

Table 3-6. Xcel coal plant assumptions

Reference Assumptions			
Plant	**Capacity (MW)**	**Retirement**	**Notes**
AS King	511	2037	Retired early in all scenarios **EXCEPT** 1,4,7,10,13,16
Sherco 1	680	2026	Planned retirement
Sherco 2	682	2023	Planned retirement
Sherco 3	517	2040	Retired early in scenarios 3,6,9,12,15 & 18

Operating assumptions for these existing coal plants are aligned with the assumptions used in Xcel's IRP modeling; key parameters that affect their dispatch include:

- Maximum power output (MW)
- Minimum stable level (MW)
- Heat rates at Pmin and Pmax (Btu/kWh)
- Minimum up & down time (hrs)
- Variable O&M cost ($/MWh)
- Forced outage rate (%)

This study assumes that the coal generators are dispatched according to signals from the broader MISO territory and not solely on the Upper Midwest system's dynamics. As such, each coal plant is modeled as a baseload, must-run unit, which can be dispatched down to the minimum power (Pmin) value if needed.

3.2.3 OTHER THERMAL RESOURCES

The remainder of Xcel's existing remaining thermal resources consist of owned and contracted natural gas, fuel oil, and biomass resources. The existing natural gas and fuel oil plants in Xcel's current

© 2019 Energy and Environmental Economics, Inc.

portfolio, along with assumed retirement dates are summarized in Table 3-7 below. In addition to these existing resources, most scenarios examined in this study (with the exception of Scenarios 6-9) assume that a new combined cycle plant is installed at the Sherco site following the closure of Sherco Units 1 & 2.

Table 3-7. Xcel natural gas and fuel oil plant assumptions

Plant	Plant Type	Capacity (MW)	Retirement
Black Dog CC	Combined Cycle	298	2032
High Bridge	Combined Cycle	606	2048
Riverside	Combined Cycle	508	2049
LS Power Cottage Grove	Combined Cycle	245	2027
Mankato Energy Center	Combined Cycle	762	2046
Angus Anson (Units 2 & 3)	Combustion Turbine	218	2035
Angus Anson (Unit 4)	Combustion Turbine	168	2035
Blue Lake (Units 7 & 8)	Combustion Turbine	351	2034
Inverhills	Combustion Turbine	369	2026
Wheaton (Units 1 - 4)	Combustion Turbine	241	2025
InvEnergy	Combustion Turbine	358	2024
Bayfront (Unit 4)	Combustion Turbine	15	2034
Black Dog CT	Combustion Turbine	232	2058
Blue Lake (Units 1 - 4)	Fuel Oil	191	2023
French Island	Fuel Oil	160	2027
Wheaton (Unit 6)	Fuel Oil	70	2025
Total		**4,792**	

Operating characteristics for Xcel's thermal resources were provided to E3 by Xcel's resource planning team. The input assumptions used in this study are the same operating characteristics as those used in Xcel's modeling in Strategist. In general, the inputs and assumptions used to characterize the costs and

constraints on operating these units are the same parameters that are provided for coal plants (maximum and minimum power, heat rates and variable O&M cost, minimum up and down time, etc.). Together, these inputs affect the economics of how each plant can be dispatched to meet Xcel's load on an hourly basis, which in turn affects the economics and value of potential new resource additions.

Xcel's existing portfolio also includes a number of contracts with small biomass facilities; together, these contracts amount to 145 MW in 2020. This analysis assumes these contracts are not renewed upon expiration; the amount of contracted capacity contracts declines to 30 MW by 2030 and 4 MW by 2045.

3.2.4 HYDRO

The Xcel Upper Midwest portfolio also includes hydrogeneration facilities and contracts. The hydro resources modeled in the portfolio include:

- Local run-of-river facilities within the Xcel Upper Midwest service territory totaling 312 MW; and
- Contracts for hydro capacity with Manitoba Hydro that total approximately 850 MWs and expire in 2025.

3.2.5 RENEWABLES

Today, Xcel Upper Midwest's renewable portfolio includes 3,800 MW of wind resources, 323 MW of utility-scale solar PV, and 671 MW of customer solar PV associated with the Solar Rewards Community program. Based on recent solicitations as well as commitments made in the prior IRP cycle, this study assumes that the following resources are added to the Xcel portfolio across all scenarios:

- 520 MW of new wind PPA by 2030;
- 1,512 MW of utility-scale solar by 2030, and an additional 571 MW by 2045; and
- 122 MW of additional customer solar by 2030.

© 2019 Energy and Environmental Economics, Inc.

3.3 New Resource Options

A broad range of new resources options are considered as candidates in the portfolio optimization process. These options generally align with those examined by Xcel in the development of its own IRP, including new gas, renewable, storage, and demand-side resources. The study also examines the impact of relicensing the nuclear plants in several scenarios. This section summarizes general assumptions on resource cost and performance used to characterize each of these options.

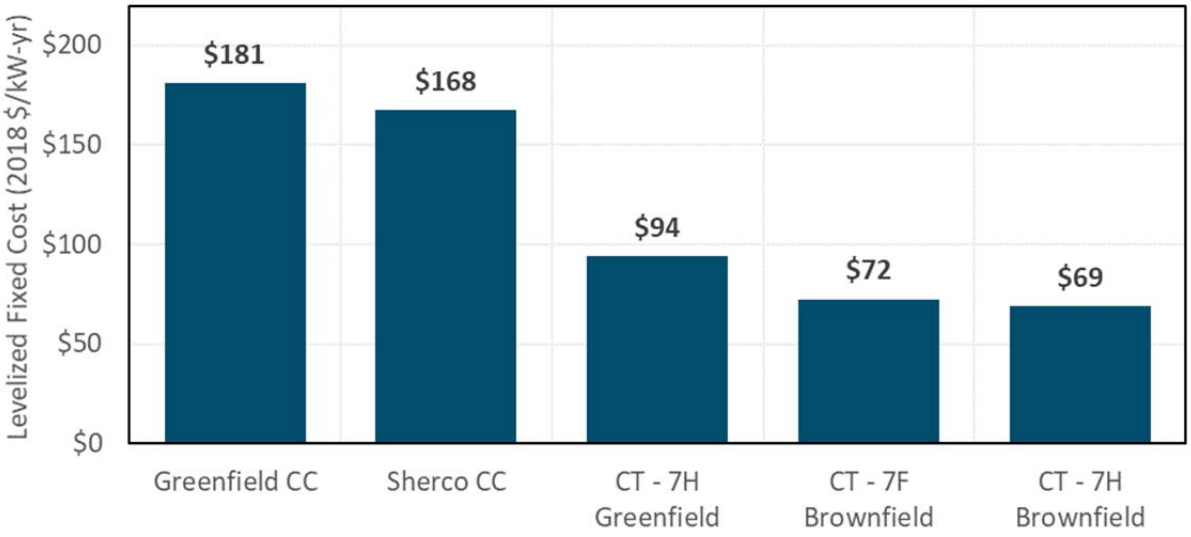
3.3.1 NATURAL GAS

Five generic gas generation resources are included as options for additional capacity:

- **Greenfield CCGT:** a generic new combined cycle plant that reflects both generation and transmission capital costs and the ongoing costs of operating the plant;
- **Sherco CC:** a new combined cycle plant located at the existing Sherco site that reflects generation costs but no interconnection or transmission costs (limited to 835 MW of potential);
- **Greenfield CT:** Greenfield 7H frame CTs are available as resource options, though an interconnection fee is required. As with the greenfield CCGT, the capacity potential is uncapped.
- **Brownfield CT:** Both 7H and 7F frames are available for selection, with the former more expensive. These resources are assumed to be built on existing sites and therefore do not require transmission costs. However, they are capacity limited to capture existing site availability constraints.

The levelized fixed costs associated with each generic gas resource in this analysis, as well as the estimated levelized cost of the Sherco combined cycle plant, were developed by Xcel Energy and provided to E3. As shown in Figure 3-2, the fixed cost per kW of CCGT is substantially higher than the cost of new combustion turbines. Gas-fired resources costs are expected to remain constant in real terms through 2050.

Figure 3-2. Levelized fixed costs of new gas generation resources.



3.3.2 RENEWABLES

Cost assumptions for new renewable resources in this study are based largely on NREL's Annual 2018 Technologies Baseline (ATB),[3] which provides an annual perspective on the current state of generation technology costs and a range of perspectives as to how those costs could change in the future. This study translates the 2018 ATB capital and fixed O&M cost assumptions for wind and solar PV (single-axis tracking) technologies into a levelized cost of energy (LCOE) metric for each type of resource that reflects an proxy for the price at which an independent developer might offer the resource to a credit-worthy utility through a long-term power purchase agreement (PPA). LCOEs for each resource vary through time due to assumed changes in technology cost, financing costs, and federal tax credits.

[3] The 2018 ATB was released in July 2018 and is available at: https://atb.nrel.gov/

© 2019 Energy and Environmental Economics, Inc.

The LCOEs for new renewable resources also include a component to capture the transmission upgrades needed to ensure that resources can be delivered to loads. Transmission costs are additive to the capital cost of the resource itself and are based on assumptions developed by Xcel as inputs for its IRP.

3.3.2.1 Wind

Table 3-8 shows the input assumptions and corresponding LCOEs for new wind resources in 2020 and 2030. Cost and performance assumptions for wind resources are translated into an LCOE that serves as an input to the portfolio optimization process. Near-term wind costs for high-quality resources are relatively low—in large part, due to the effect of the Federal Production Tax Credit (PTC); in the long run, the LCOE of wind is assumed to increase from today's level due to the expiration of the PTC, an effect that is partially offset by some improvements in capital costs.

LCOEs for new wind resources—both for the Base Case assumptions reported in Table 3-8 and the alternative high and low cost assumptions used in sensitivity analysis—are shown in Figure 3-3. The near-term trajectory of costs is heavily shaped by the expiration of the PTC, which results in a near-term cost increase; in the long run, the LCOE for new wind resources declines slightly in real terms as technology continues to improve at a modest pace.

Table 3-8. Key technology parameters for new wind resources

		Installation Year		
Assumption	**Units**	**2020**	**2030**	**Source**
Capital cost	$/kW	$1,531	$1,381	NREL Annual Technologies Baseline (TRG 2)
Transmission cost	$/kW	$400	$400	Xcel IRP assumption
Fixed O&M	$/kW-yr	$52	$48	NREL Annual Technologies Baseline (TRG 2)
Capacity factor	%	50%	50%	Xcel IRP assumption
Tax credit	$/MWh	$18	—	Federal Production Tax Credit
Financing costs				E3 standard pro-forma PPA assumptions

3.3.2.2 Solar

Table 3-9 shows the input assumptions and corresponding LCOEs for new solar resources in 2020 and 2030. Cost and performance assumptions for solar resources are translated into an LCOE that serves as an input to the portfolio optimization process. While the Federal Investment Tax Credit (ITC) available to solar resources today is scheduled to revert to a lower level of 10% in the next few years, continued anticipated cost reductions in capital costs over time helps to offset the effect of the sunsetting ITC on the resulting LCOEs for solar resources.

Figure 3-4 shows the trajectory of solar LCOEs through 2050 under the Base Case assumptions above, as well as the high and low ranges used in the technology cost sensitivities.

Table 3-9. Key technology inputs for new solar resources

		Installation Year		
Assumption	**Units**	**2020**	**2030**	**Source**
Capital cost	$/kW	$1,355	$1,154	NREL 2018 Annual Technologies Baseline
Transmission cost	$/kW	$140	$140	Xcel IRP assumptions
Fixed O&M	$/kW-yr	$11	$9	NREL 2018 Annual Technologies Baseline
Capacity factor	%	23%	23%	RESOLVE solar profiles
Tax credit	%	30%	10%	Federal Investment Tax Credit
Financing				E3 standard pro-forma PPA assumptions

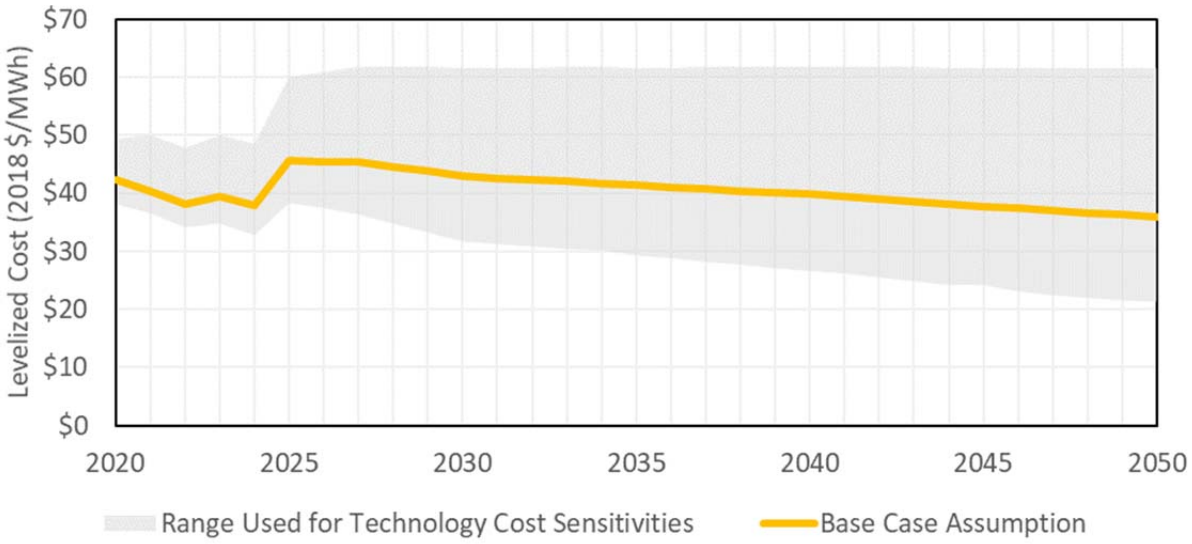
Figure 3-4. LCOE projections for new solar resources: Base Case and High & Low Technology Cost sensitivities



3.3.3 ENERGY STORAGE

The reliability and portfolio optimization analyses consider energy storage as a potential resource addition. Cost assumptions for new energy storage are based on Lazard's Levelized Cost of Storage 4.0,[4] which provides an assessment of the state of market for battery storage and a forward-looking projection of costs over a five-year period through 2022. Cost projections beyond this 2022 timeframe are derived by extrapolation of the cost declines anticipated in the next five years. While Lazard's study considers many technologies and applications in its assessment of the market, this study relies upon Lazard's characterization of a utility-scale battery system with four hours of duration. Table 3-10 presents the cost assumptions and corresponding levelized costs for a new four-hour battery.

Figure 3-5 shows the levelized fixed cost assumptions for battery storage across the analysis horizon.

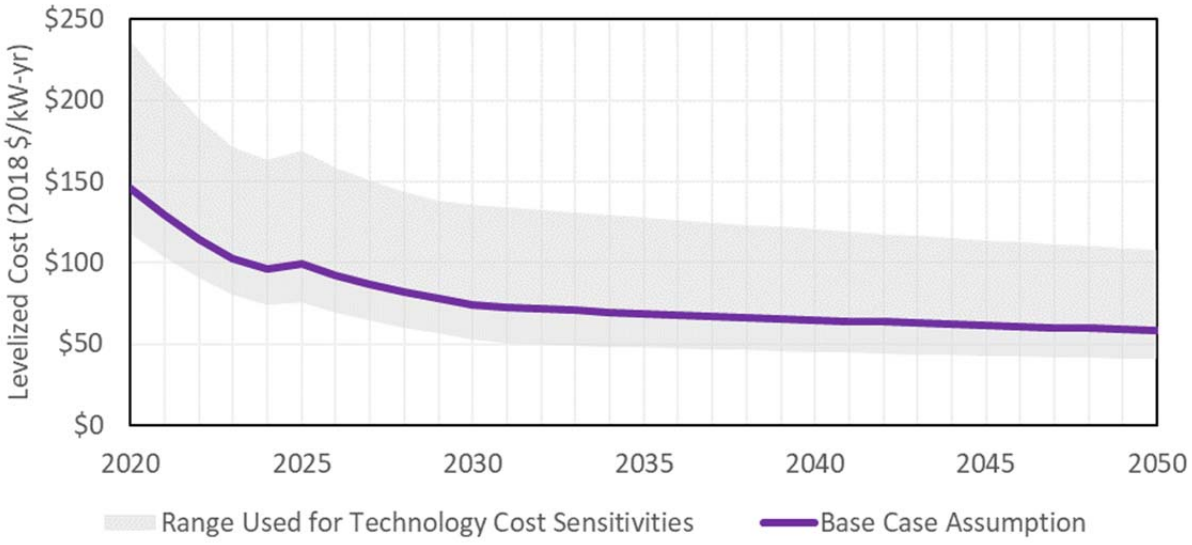
Figure 3-5. Levelized cost projections for new storage resources: Base Case and High & Low Technology Cost sensitivities



3.3.4 NUCLEAR RELICENSING

Costs associated with maintaining and operating existing nuclear plants are broken into three categories:

- Ongoing fixed O&M: routine annual non-fuel costs associated with operating and maintaining the plant, incurred each year it is in operations;
- Fuel costs: costs associated with procurement of uranium to fuel reactors, incurred for each unit of energy generated; and
- Incremental relicensing cost: additional costs incurred on an annual basis associated with plant relicensing that are incurred beginning in the year after relicensing (applicable only in scenarios in which the plants are relicensed).

All cost assumptions for nuclear plants, including the increase in fixed costs associated with license extensions, were provided by Xcel.

3.3.5 DEMAND RESPONSE

New demand response resources are included as options to satisfy the need for new generation capacity. The cost and potential for new demand response is consistent with the Xcel IRP data assumptions. In the Xcel system there are three demand response programs capable of contributing to the need for peaking capability: (1) Saver's Switch, (2) Interruptible tariffs, and (3) Critical Peak Pricing (CPP). A supply curve of three bundles, each bundle comprising all three measures, is available for selection within the optimization; these bundles are summarized in Table 3-11 below.

© 2019 Energy and Environmental Economics, Inc.

Table 3-11. Assumed cost and potential for new demand response resources

Program Type	Levelized Cost ($/kW-yr)	Maximum Technical Potential (MW)					
		2020	2025	2030	2035	2040	2045
Bundle 1	$54	270	380	456	567	717	717
Bundle 2	$71	107	145	189	257	352	352
Bundle 3	$130	89	110	110	116	135	135
Total		**467**	**635**	**755**	**940**	**1,204**	**1,204**

3.3.6 ENERGY EFFICIENCY

In this study, the model can optimize Xcel's new energy efficiency (EE) programs to meet a portion of future energy and capacity needs; this may also contribute to meeting carbon reduction goals. The data for capacity, potential, impacts shapes, and costs for energy efficiency is consistent with the Xcel IRP data. Measures were grouped into three categories according to cost and potential: (1) Program Achievable, (2) Optimal, (3) Maximum Achievable. The Program Achievable and Maximum Achievable bundles were developed based on the Minnesota Energy Efficiency Potential Study[5], while the Optimal bundle was developed by Xcel. This study optimizes the EE programs through 2034 and then holds the resulting level constant through the rest of the modeling period. The supply curve used in this study is shown in Figure 3-6. The levels of potential load reduction shown in Figure 3-6 represent the maximum impacts from the supply curve through 2034. The potential annual load and peak load impacts of the EE bundles are cumulative over time. The impacts on annual load and peak load assumptions are shown in Figure 3-7.

3.4 Hourly Profiles

Hourly profiles for load and wind and solar resources are key inputs to this study. Load, wind, and solar each vary on an hourly, daily, and seasonal basis, and their variations are often correlated due to underlying meteorological phenomena that affect all three. Capturing these patterns in a statistically rigorous manner is crucial to enable planning of a system that can operate efficiently on a day-to-day basis and is resilient in spite of an increasingly intermittent and variable energy supply.

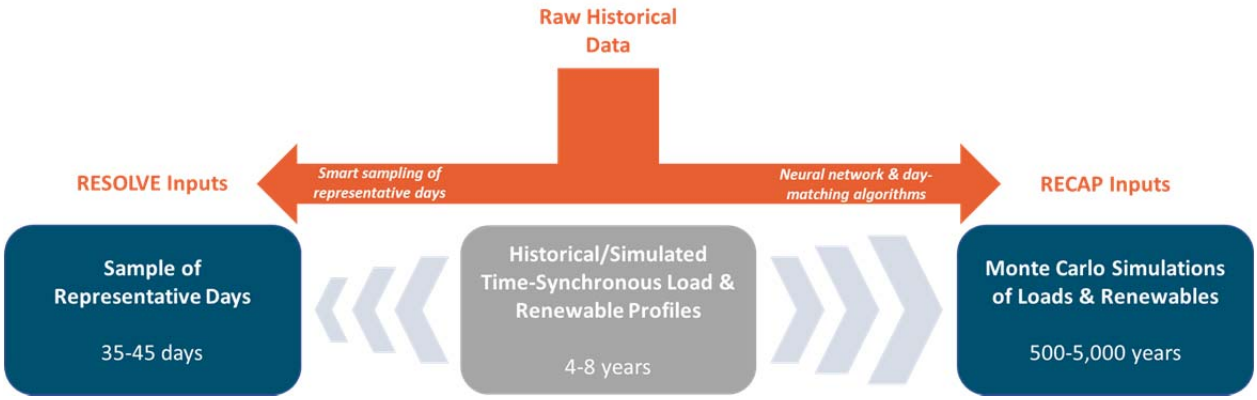
This study relies on a library of hourly load, wind, and solar profiles that reflect the meteorological conditions across the four-year time span from 2009 through 2012. Developing profiles that are weather-matched and time-synchronized in this manner ensures consistency across the data set, preserving the key underlying correlations among the variables. The hourly profiles for this study are based on the following sources:

- Load profiles for current end uses on the Xcel Upper Midwest system are based on actual metered historical loads for the 2009-2012 period;
- Load shapes for end uses that may be electrified in the future (e.g. space heating, water heating)—used only in the High Electrification sensitivity—are simulated based on hourly historical weather data using building simulation software;
- Wind profiles are developed for the same period using data from NREL's WIND Toolkit, which provides detailed geospatial simulations of wind speed and generation profiles for a large number of sites throughout the United States;
- Solar PV profiles are simulated using NREL's System Advisor Model (SAM) and solar irradiance data from the National Solar Radiation Database (NSRDB) for a variety of plausible locations throughout the Xcel Upper Midwest territory;

This library of profiles serves as a foundational dataset of inputs for both the reliability and the portfolio analysis. However, the series themselves are used in different ways, as depicted in Figure 3-8. In RECAP,

these series are extended through simulation of a much longer historical weather record; capturing such a broad set of plausible weather conditions is essential when examining whether a system is designed to meet a "one-day-in-ten-year" reliability standard. In contrast, in RESOLVE, a reduced representative subset of 37 days is used to enable portfolio optimization across multiple decades, sampled to reflect representative combinations of loads and associated renewable production profiles, from the time series described. For additional information on this process, see Appendix C.1.

Figure 3-8. Schematic of development of hourly profile inputs for RECAP & RESOLVE



3.5 Fuel Price Forecasts

Fuel prices were derived from Xcel's data of generators and their associated fuels and fuel costs. To arrive at a representative fuel price trajectory by resource, plants were binned into their respective fuel types and the average annual fuel price of each resource was then calculated. Fuel oil and biomass prices are both expected to decline in real terms through 2050 while coal and natural gas are expected increase in price. Fuel price projections used in this study are summarized in Table 3-12.

© 2019 Energy and Environmental Economics, Inc.

Table 3-12. Fuel price forecasts ($/MMBtu)

Fuel Type	2020	2025	2030	2035	2040	2045	CAGR ('20-'45)
Coal	$2.03	$2.11	$2.18	$2.26	$2.34	$2.35	**0.6%**
Fuel Oil	$16.44	$15.52	$15.31	$15.11	$14.93	$14.77	**-0.4%**
Natural Gas	$2.59	$3.06	$3.44	$3.74	$4.01	$4.08	**1.8%**

Fuel prices are shaped on a monthly basis to capture the seasonal differences in costs; the degree of seasonal adjustment depends on the fuel. Natural gas, whose demand varies significantly on a seasonal basis due to heating loads in the winter, has the most significant differences in assumed pricing by month, whereas other fuels' prices remain relatively constant throughout the year. Seasonal shaping factors for each fuel are shown in Table 3-13.

Table 3-13. Seasonal shaping factors, expressed as a percentage of annual average price

Month	Coal	Fuel Oil	Natural Gas
January	100%	97%	111%
February	100%	101%	109%
March	100%	101%	103%
April	100%	101%	95%
May	100%	101%	93%
June	100%	101%	93%
July	100%	100%	95%
August	100%	100%	96%
September	100%	100%	96%
October	100%	100%	97%
November	100%	100%	104%
December	100%	99%	109%

In addition to the Base Case forecast for natural gas, this study also tests the impacts of high and low gas price sensitivities on key results and conclusions. These high and low sensitivities begin to diverge from the base forecast in 2022 and are based on adjustments of the base forecast 2018 – 2057 nominal CAGR, which is consistent with Xcel's modeling. In the Low Gas Price and High Gas Price sensitivities, prices grow at rates 50% lower and 50% higher than the Base Case (in nominal terms). The corresponding gas price forecasts associated with each sensitivity are shown in Table 3-14.

Table 3-14. Sensitivities on natural gas price forecasts in 2018 $

Fuel Type	2020	2025	2030	2035	2040	2045	CAGR ('20-'45)
Base Case	$2.59	$3.06	$3.44	$3.74	$4.01	$4.08	**1.8%**
Low Gas Price	$2.59	$2.88	$2.99	$3.00	$2.98	$2.80	**0.3%**
High Gas Price	$2.59	$3.26	$3.96	$4.64	$5.38	$5.92	**3.4%**

One area where this analysis does deviate notably from the analysis conducted by Xcel to support its integrated resource plan is in the treatment of carbon emissions costs. Under direction from the Public Utilities Commission, Xcel includes an explicit carbon cost in the evaluation and comparison of costs among portfolios in its IRP. Because the scenarios in this study are instead designed to meet a specific carbon goal, and to measure the cost associated with achieving that level of carbon reduction, an explicit carbon price adder is not included.

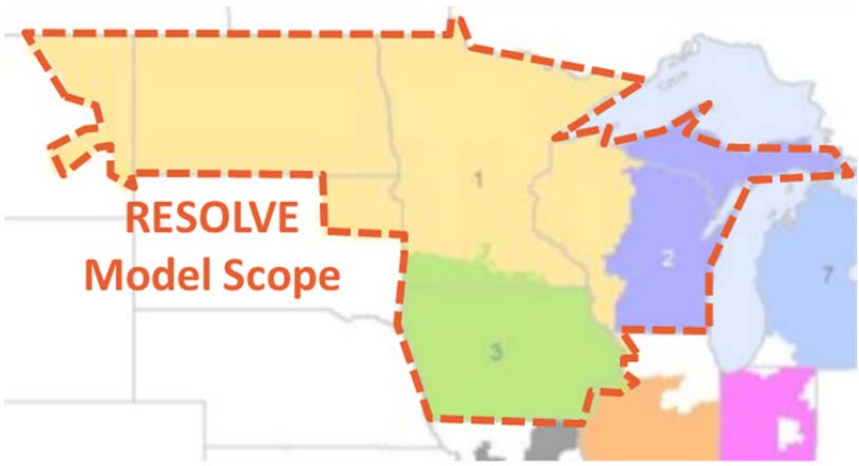
3.6 MISO Market Representation

Xcel's Upper Midwest system is a part of the Midwest Independent System Operator (MISO) pool. Membership in MISO provides Xcel with numerous benefits, including the ability to trade energy in a deep and liquid wholesale market on an hourly (and subhourly) basis, sharing of operating reserves

© 2019 Energy and Environmental Economics, Inc.

across a broad pool, and a lower planning reserve margin requirement that captures the benefit of load diversity across the MISO footprint.

Figure 3-9. Geographic scope of RESOLVE analysis



Each of these dynamics is accounted for in the optimization of Xcel's long-term resource portfolio to meet carbon reduction objectives.

- In addition to optimizing the investments and operations of the Xcel portfolio, RESOLVE simulates least-cost dispatch of the broader MISO pool (Load Resource Zones [LRZ] 1-3, as shown in Figure 3-9) on an hourly basis. This simulation thus allows for both purchases from and sales to the wholesale market, which are priced at the marginal cost of energy in the relevant zone. The assumed buildout and retirement of new resources to serve loads other than Xcel's own are based on MISO's "Continued Fleet Change" scenario as developed in its 2018 MISO Transmission Expansion Plan (MTEP) planning process. Market transactions between Xcel and the MISO are limited to 1,800 MW through 2023; thereafter, the limit is expanded to 2,300 MW through the rest of the modeling period.
- Operating reserve requirements are maintained at the current level that Xcel must provide today as a member of MISO:

1. Load following reserves requirements are set at 3% of load;
2. Frequency regulation reserve requirements are 27 MW; and
3. Spin reserve requirements are set at 1% of load.

+ The planning reserve margin requirement imposed upon Xcel's portfolio in this study—3% above Xcel's own system peak demand—reflects the benefit of diversity among Xcel's load profile and the other members of MISO.

Detailed load and resource assumptions for the external zones are presented in Appendix C.2.

4 Reliability Analysis Results

4.1 Effective Load Carrying Capability Analysis

The capacity contribution towards resource adequacy of dispatch-limited resources – variable resources like wind and solar PV, and energy-limited resources, like storage and DR – is evaluated dynamically within RESOLVE based on the metric of ELCC. The concept of ELCC is most widely used to quantify the capacity contribution of a resource whose availability changes on an hourly basis; it represents the quantity of perfectly dispatchable generation that could be removed from the system by an incremental dispatch-limited generator. Essentially, the ELCC represents the capacity value each resource can contribute to the resource adequacy needs of the Xcel Upper Midwest system. This value depends on both the coincidence of each resource with peak loads and the characteristics of the other dispatch-limited resources on the system.

In this study, E3 used RECAP – a loss of load probability (LOLP) model – to evaluate the ELCC provided by a range of different portfolios of wind, solar, storage, and DR resources under specific conditions of load and generation resources in the Upper Midwest service territory; these ELCC values are not representative of ELCC values of resources in the broader MISO territory. The capacity value results from each RECAP run, associated with varying penetrations of wind, solar PV, storage, DR, are used to calculate marginal ELCC curves.

The marginal ELCC values for variable and use-limited resources used in this study are shown in Figure 4-1 and Figure 4-2. below.

Figure 4-1. Marginal ELCC of wind and solar resources for the Upper Midwest system in 2030

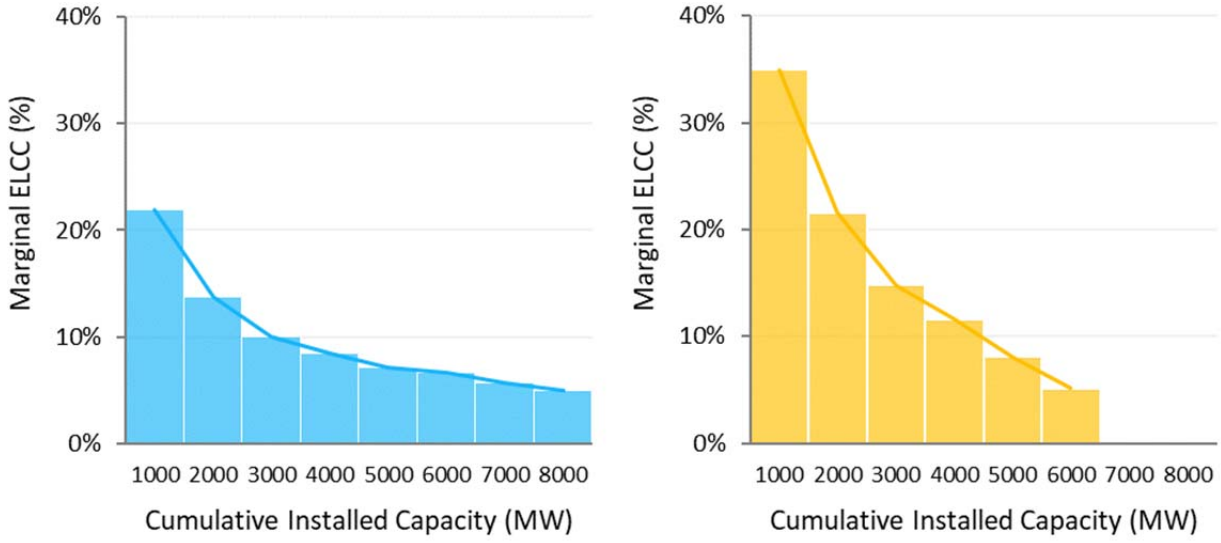

Figure 4-2. Marginal ELCC of 4-hr storage and DR resources for the Upper Midwest system in 2030

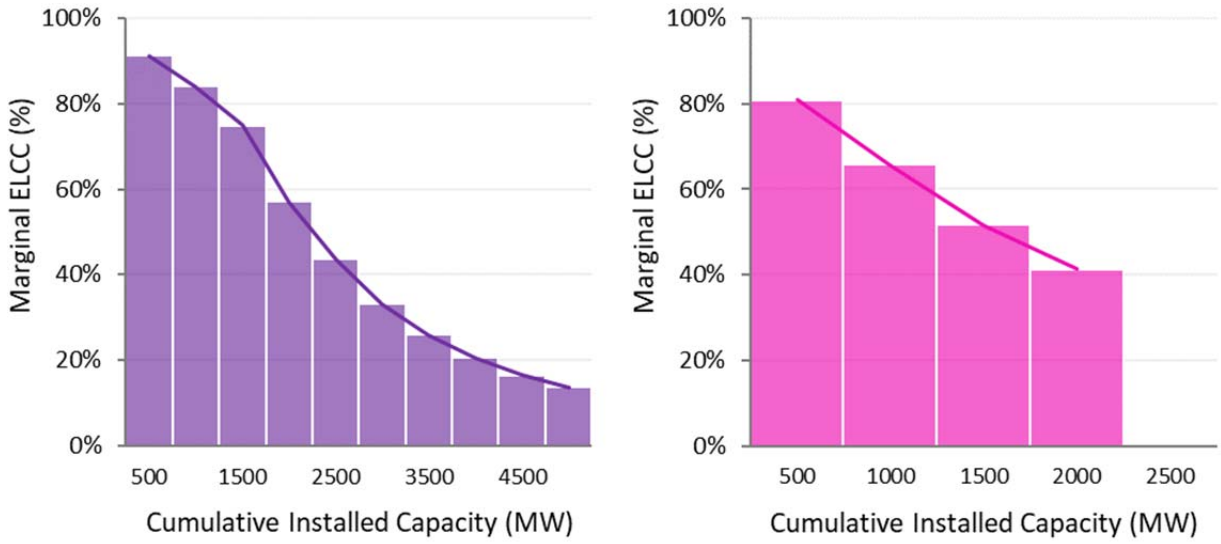


© 2019 Energy and Environmental Economics, Inc.

Generally, as the penetration of any individual resource type grows, the its marginal capacity value decreases. This effect is well-established and understood for variable resources such as wind and solar; adding incremental quantities of these resources generally shifts periods of loss-of-load-probability towards periods when the resources produce less energy. For instance, as shown in Figure 4-1, the first 1,000 MW of wind resource has an ELCC of approximately 22%; the next 1,000 MW has an ELCC of about 15%; and the third 1,000 MW has an ELCC of 10%. Solar exhibits a similar decline in ELCC with increasing levels of deployment, an effect that results primarily from the shifting of the period of the net peak away into the evening hours when solar resources do not produce energy.

Despite significant differences in their characteristics compared to variable resources, use-limited resources like storage and DR also exhibit declining marginal ELCC; this effect is shown in Figure 4-2.. Initially, the marginal ELCC of a four-hour storage resource is relatively close to 100%: this reflects the fact that small amounts of storage can be dispatched when called upon to reduce load during periods of peak demand. However, as progressive amounts of storage are added to the system, their dispatch has the effect of flattening and broadening the peak period, eventually requiring resources that are capable of dispatching (or discharging) over longer extended periods. As a result, the relative effectiveness of a battery system with limited duration (when compared with a traditional firm resource) diminishes. This effect may be countered by extending the duration of the storage system (i.e. adding more cells to the battery system), though the cost of the additional cells may outweigh the incremental value it provides.

To ensure that the optimized generation fleet is sufficient to meet the Xcel Upper Midwest system's resource adequacy needs throughout the year, the ELCC curves shown above are incorporated into RESOLVE as input assumptions. These inputs enable RESOLVE to solve for a portfolio that meets a target planning reserve margin while accounting for the inherent cumulative limitations of variable and use-limited resources.

4.2 100% Carbon-Free Portfolio Analysis

A secondary question explored through the reliability analysis is the extent to which the future needs of Xcel's customers can be met exclusively through reliance on carbon-free resources. The declining ELCC curves shown above hint at the idea that the potential contributions of variable and use-limited resources towards reliability needs is pragmatically limited. This study uses RECAP to design two hypothetical portfolios that rely exlusively on a combination of carbon-free resources to meet Xcel's long-term reliability needs under a one-day-in-ten-year reliability standard: (1) a first porfolio that includes Xcel's existing nuclear plants and a combination of wind, solar, and storage resources; and (2) a second portfolio that relies exclusively on wind, solar, and storage. These portfolios are constructed to adhere to the following criteria:

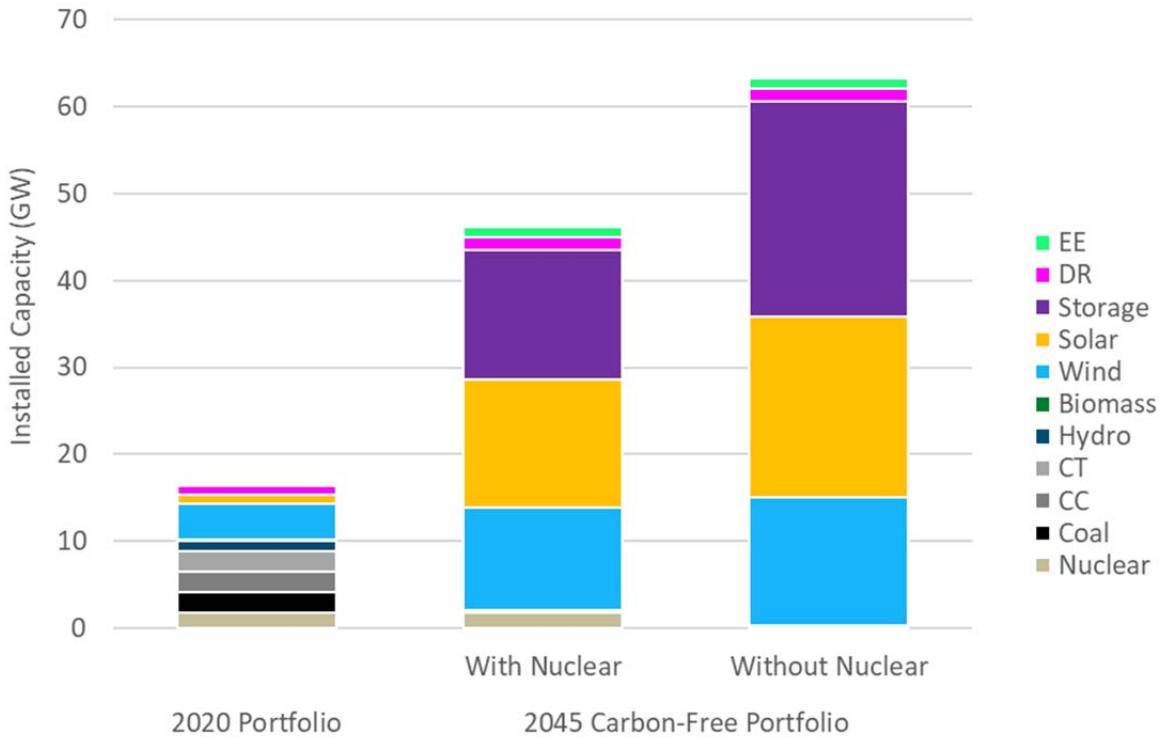
- Each portfolio must comprise only carbon-free resources;
- Each portfolio must adhere to an LOLE standard of one day in ten years; and
- Each portfolio may not rely on the MISO market to supply wholesale power beyond the carbon-free resource that specifically make up the portfolio due to the fact that such generic wholesale purchases cannot be certified as carbon-free.

Each portfolio is created directly in RECAP through an iterative addition of wind, solar, and storage to Xcel's existing carbon-free resources until the appropriate reliability standard has been met;[6] this approach inherently achieves the goal of a carbon-free energy system. The resulting portfolios are shown in Figure 4-3.

[6] Resources are added in this iterative process according to an algorithm that adds small quantities of individual resources one at a time, in each step adding a discrete quantity of the resource that provides the highest marginal reliability benefit (i.e. reduction in LOLE) per unit of fixed cost.

© 2019 Energy and Environmental Economics, Inc.

Figure 4-3. Total installed capacity to meet 2045 reliability needs with a fully decarbonized portfolio.



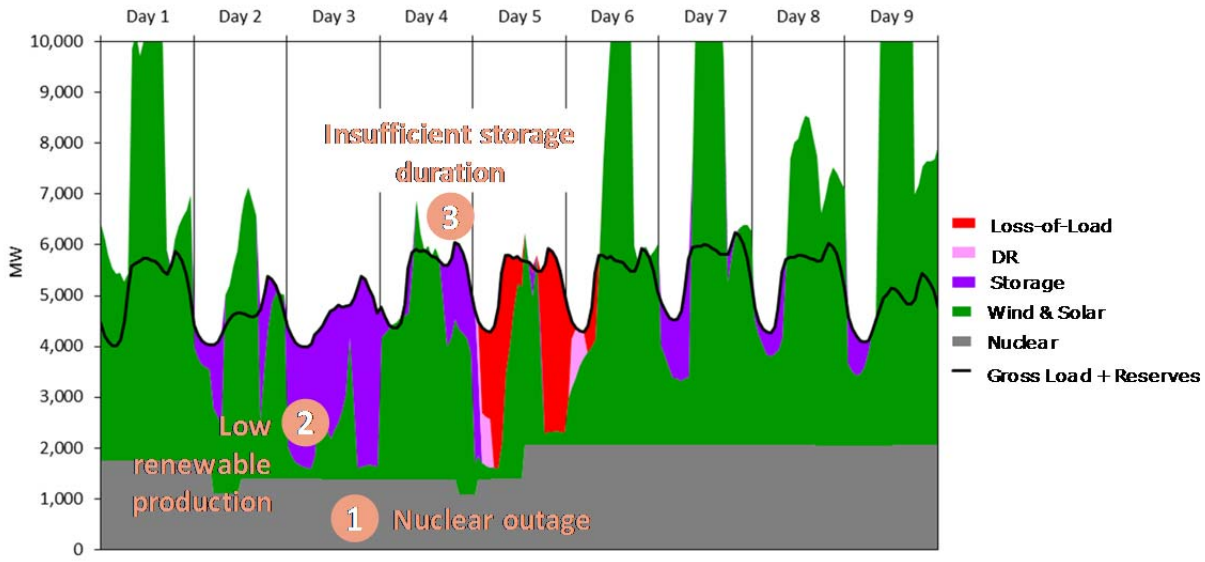
As shown above, the infrastructure requirements associated with meeting such objectives are incredibly large: while Xcel's projected system peak (not considering impacts of additional efficiency) is slightly larger than 12 GW in 2045, the total installed capacity needed to achieve reliability ranges from 45-60 GW, the vast majority of which comprises a mix of wind, solar, and storage. On an annual basis, these portfolios are capable of producing more than double the amount of energy needed to satisfy Xcel's Upper Midwest system demand; the overbuild is a consequence of the requirement that resources must be sufficient to meet demand not only under average conditions but under all but the most stringent conditions, including both periods of extreme high demand and sustained low renewable availability.

To illuminate the drivers of the large quantity of infrastructure needed to meet reliability needs with a combination of wind, solar, and storage, Figure 4-4 shows a nine-day snapshot of resource availability extracted from RECAP's loss-of-load-probability simulation in the portfolio that includes Xcel's existing nuclear plants. While traditionally loss-of-load-probability modeling has focused on ensuring resource sufficiency during periods of peak demand, these nine days highlight a new type of event that would ultimately lead to potential resource shortages on such a system: extended periods of low resource availability. Specifically, the loss-of-load event highlighted below—one of the rare events permitted under a "one-day-in-ten-year" standard—is a result of the following sequence of events:

- A unforced outage at one of Xcel's existing nuclear plants begins on the second day, reducing the amount of firm, baseload generation available to serve Xcel's load.
- This outage extends into the third day, coinciding with a period of low renewable availability, when the combined output of wind and solar resources is substantially lower than most typical days in that season (see, for example, Day 1 or Days 6-9) and is insufficient to meet load on its own in any hour.
- These two factors, in turn, require Xcel to discharge energy stored in its battery storage resources to meet load throughout the third day, depleting a large portion of their state of charge.
- While the level of renewable production increases on the fourth day, it remains below "typical" levels for this season and is merely sufficient to meet Xcel's load in most hours—but does not provide a surplus to restore state of charge to the energy storage systems.
- By the beginning of the fifth day, the state of charge of the energy storage systems has been fully depleted, and the lack of available renewable resources during non-daylight hours leaves the operator with no other option but to shed significant quantities of load—a major loss-of-load event that extends across most of the day and represents a substantial portion of Xcel's customers.

© 2019 Energy and Environmental Economics, Inc.

Figure 4-4. Illustrative sample of hourly dispatch patterns in a 100% Carbon Reduction Scenario



This illustrative sequence of events demonstrates that the challenge of relying exclusively on carbon-free resource options to serve load shifts from meeting peak hourly demands to meeting load across extended periods of low renewable availability; the types of weather events of concern on such a system shift from those that drive extreme levels of load (e.g. summer heat waves) to those that inhibit renewable production across extended periods (e.g. extended/extreme winter storms). This type of event hints at the types of resources that would provide the most value, from a reliability perspective, in a system that is heavily reliant on renewables: those that can be dispatched on demand at full capacity for periods of up to several days, but are rarely called upon to do so. Based on today's commercially available technologies and at current prices, natural gas combustion turbines arguably remain the most viable candidate resource to complement a portfolio of wind, solar, and storage resources due to their relatively low up-front cost and expectation of limited operations.

This analysis also underscores the value of Xcel's participation in the MISO wholesale market, if only indirectly. Today, Xcel and MISO's other member utilities benefit from the diversity of loads and resources through a collective reduction in the capacity needs to meet resource adequacy requirements; this is manifest as a lower planning reserve margin target for each member than would be required if they were to plan exclusively to meet their own reliability needs. Under a requirement that all load be served by carbon-free generation, this analysis assumes that Xcel would forego this benefit, magnifying the system's resource need while restricting the available options to meet it. This, in turn, suggests that careful consideration be given in clean energy target-setting and policy design to balance the aggressiveness of goals with their implications for the efficiency of markets, as imprudent choices could negate the widely-recognized benefits achieved through centralization of wholesale market operations.

5 Portfolio Analysis Results

This section highlights the results of some of the main cases and sensitivities used to help answer the key questions surrounding Xcel's strategy to meet their climate goals. These results are presented in sections aligned with these questions: how much coal, if any, should Xcel retire; is new gas necessary or unnecessary to serve load reliably; and what value does Xcel's current nuclear fleet provide, given its carbon-free generation attribute? While all the cases were modeled from 2020 through 2045 in increments of five years, for many of these questions, focusing on one specific year helps provide the answer. This section focuses primarily on analytical results in 2030 or 2045, which generally coincide with Xcel's near-term and long-term climate goals.

5.1 Reference Case

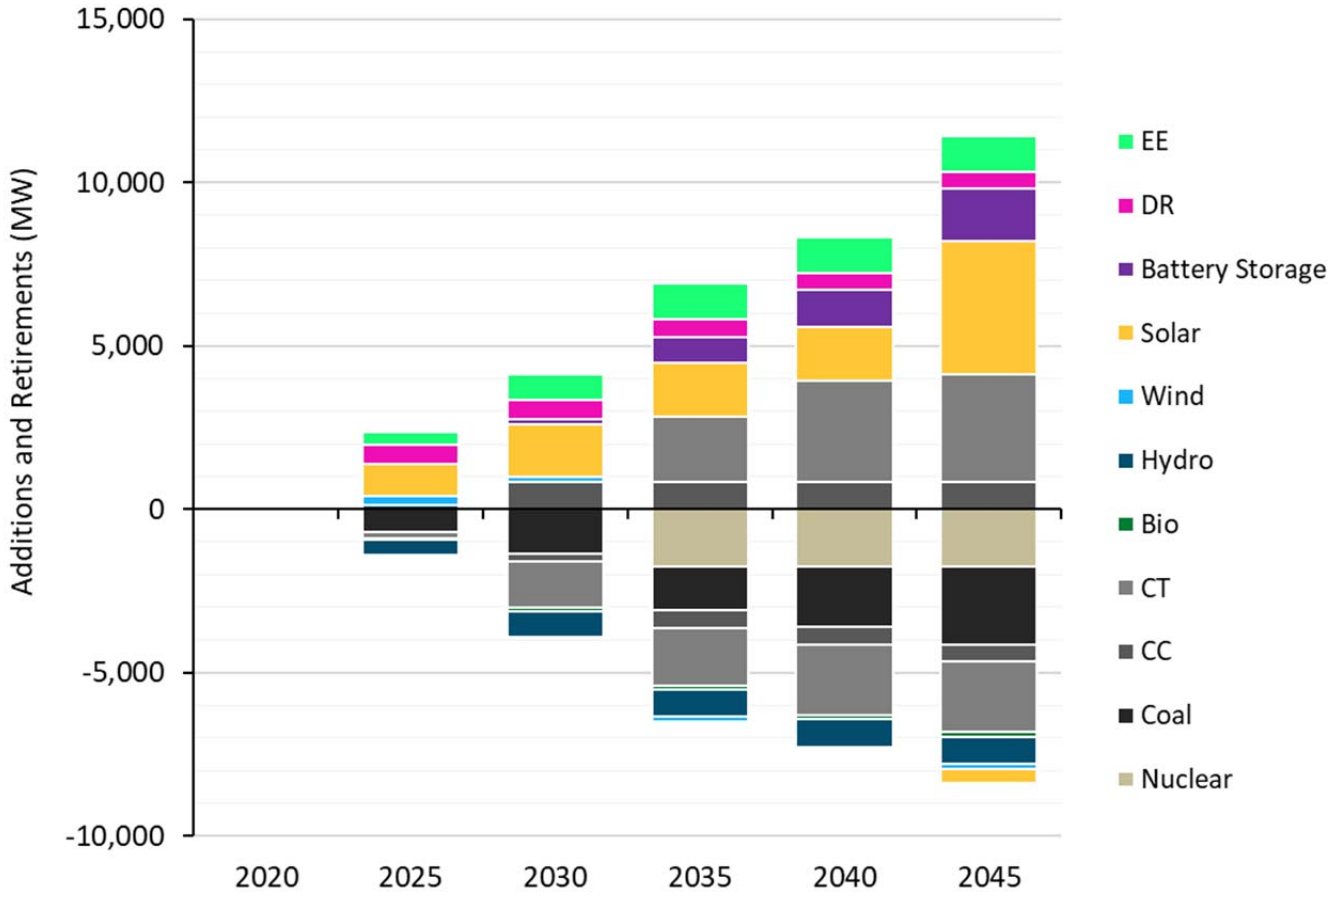
The Reference Case represents a least-cost plan to meet future energy and capacity needs of Xcel's Upper Midwest system through 2045 given expected growth in demand and anticipated plant retirements across this period, absent any specific clean energy or carbon goals beyond current state policy. Accordingly, the Reference Case is not compliant with Xcel's current greenhouse gas goals. Instead, this case represents a "business-as-usual" scenario that serves as a useful point of comparison against which to measure cost and greenhouse gas impacts of more aggressive decarbonization scenarios.

Figure 5-1 below shows the resource additions and retirements across the analysis horizon, including both Xcel's prior commitment as well as new resources selected in RESOLVE's to meet future needs. By

2030, Sherco Units 1 and 2, representing 1.4 GW of firm capacity, as well as a total of 1.6 GW of existing gas plants are retired. This retiring capacity is replaced by a diverse portfolio of resources that includes battery storage, utility-scale solar, a new combined cycle plant at the Sherco site, an expansion of existing DR programs, and deployment of energy efficiency at levels above historical state standards. Similar general dynamics continue through the analysis horizon: by 2045, the remaining coal and nuclear capacity, as well as some aging gas units, are retired, replaced primarily by additional energy storage, solar, and new gas combustion turbines.

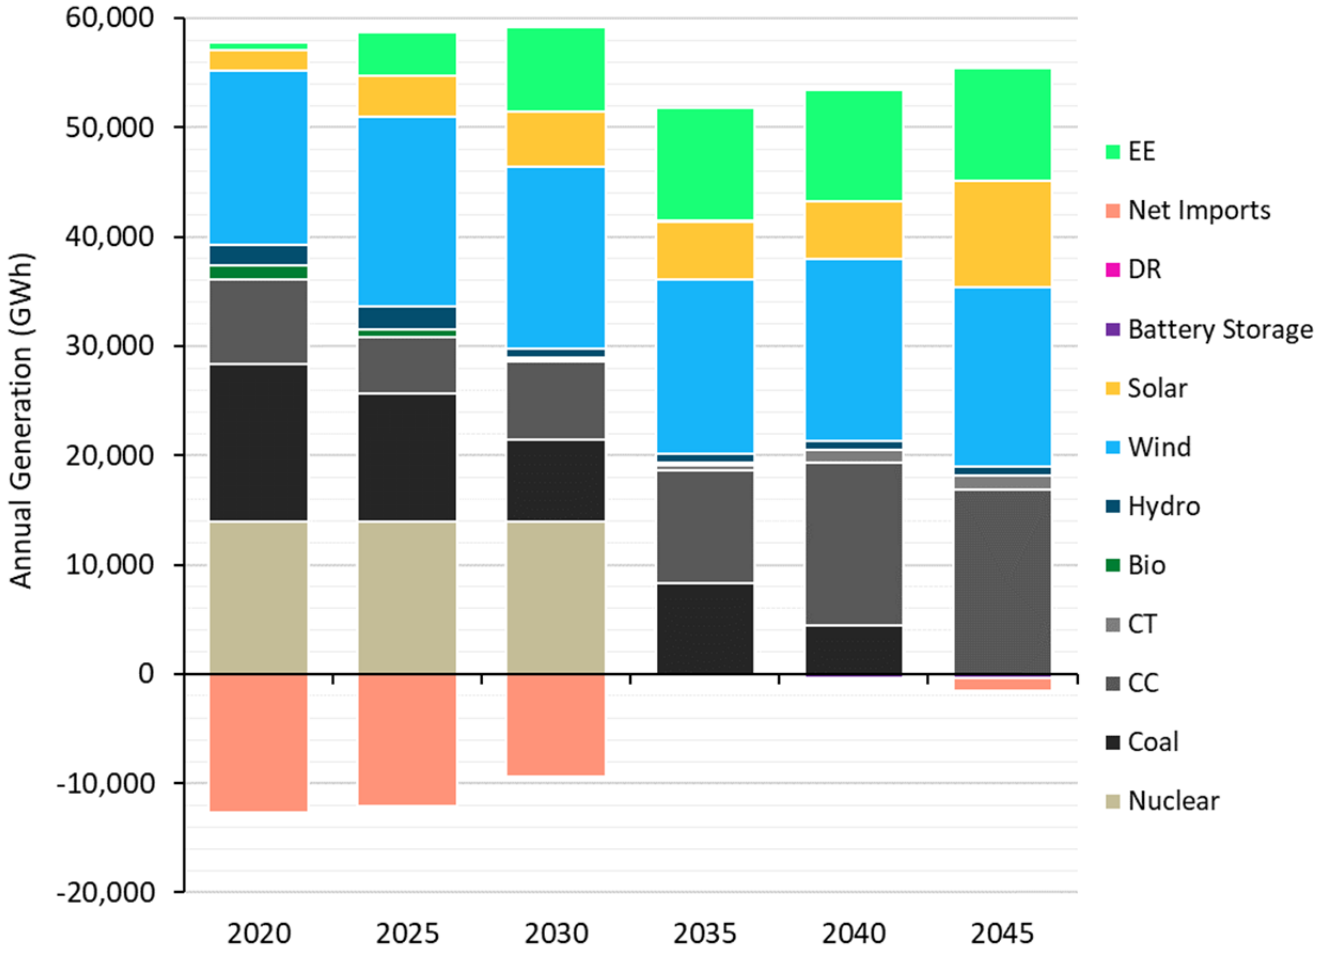
© 2019 Energy and Environmental Economics, Inc.

Figure 5-1. Reference Case capacity additions and retirements over study horizon



The annual generation mix in Figure 5-2 shows that despite the absence of a carbon target, the Reference Case generation mix across this period generally shifts away from the most carbon intensive resources (coal) and towards carbon-free alternatives (wind, solar, efficiency), the notable exception resulting from the retirement of existing nuclear plants shortly after 2030, prompting an increase in gas generation. These trends yield some carbon reductions in the near term—Xcel's 2030 emissions are roughly 60% below 2005—but are insufficient to achieve the level contemplated in this study.

Figure 5-2. Reference Case generation mix across analysis horizon



5.2 Summary of Carbon Reduction Scenarios

This study analyzes a wide range of scenarios to achieve its primary purpose—to examine the cost implications of viable strategies to meet its 2030 emissions goal and to achieve alignment with an emissions reduction pathway consistent with its ultimate 2050 goal of 100% carbon-free generation.

© 2019 Energy and Environmental Economics, Inc.

Each scenario is therefore designed to meet milestones of 85% carbon reductions by 2030 and 95% carbon reductions by 2045.

Each scenario achieves these milestones through a unique combination of plant retirements of key existing generation assets (coal and nuclear) and investment in new resources (efficiency, renewables, storage, and natural gas). Additions and retirements across the full set of scenarios are shown in Figure 5-3 for 2030 and Figure 5-4 for 2045.

Figure 5-3. Additions and retirements for full sets of scenarios in 2030

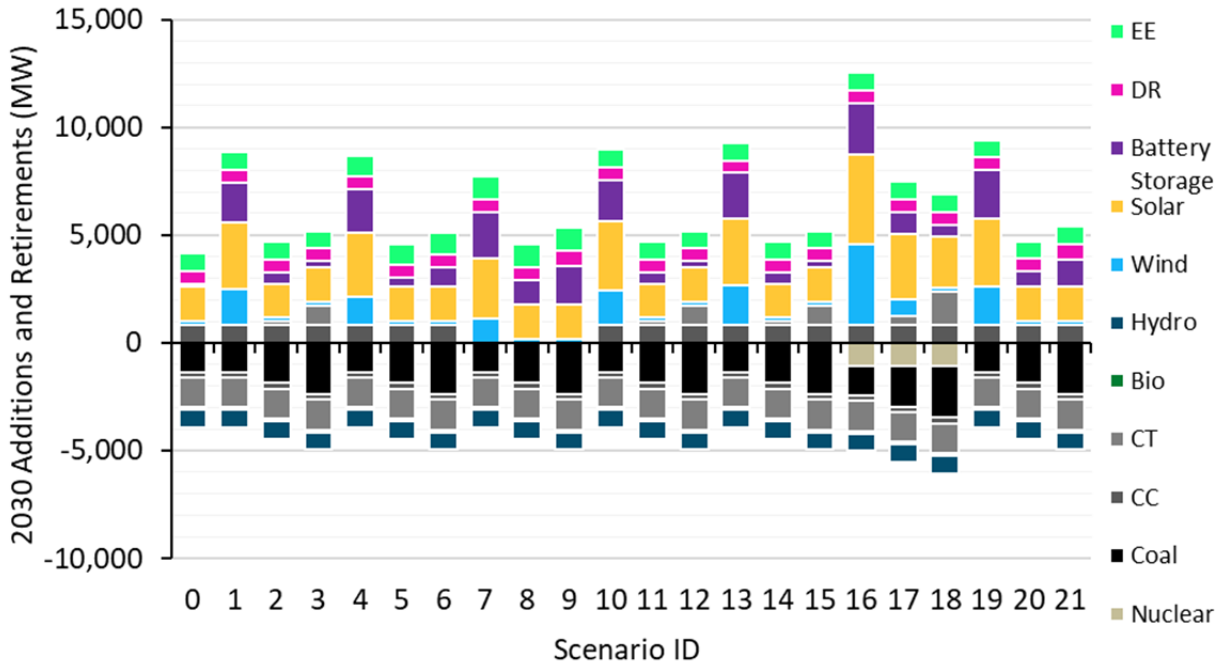


Figure 5-4. Additions and retirements for full set of scenarios in 2045

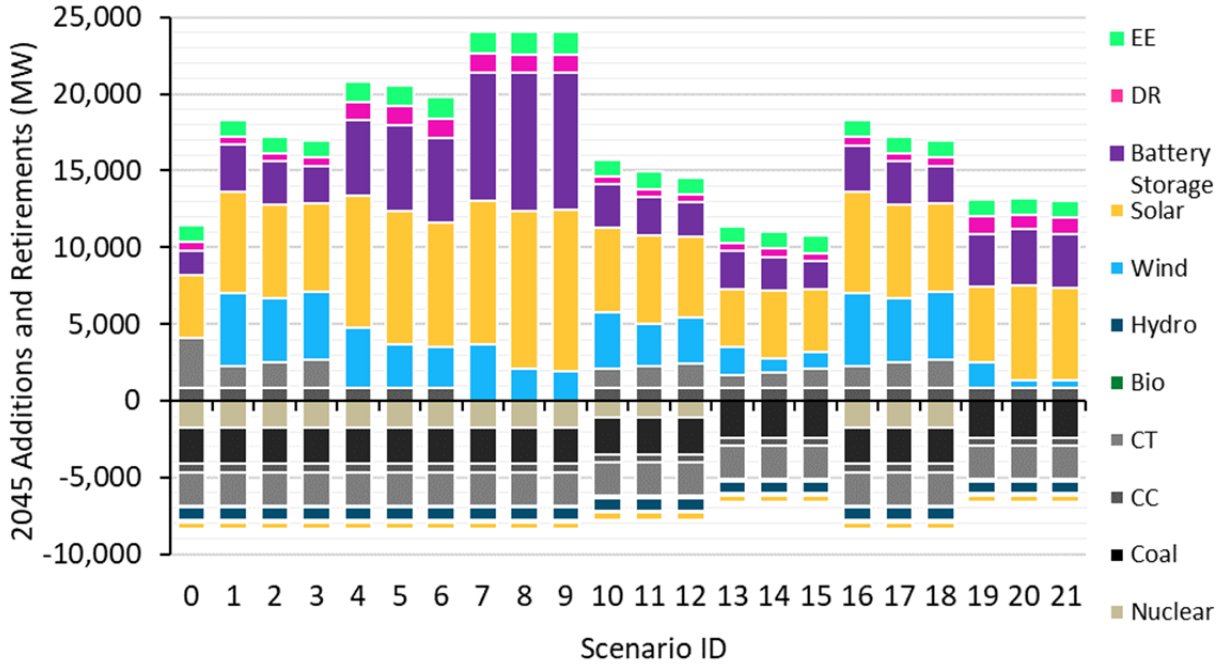

While the specific changes to Xcel's portfolio vary widely depending on the design of each scenario, several common themes are immediately apparent across all:

- Xcel's least-cost portfolios rely heavily on energy efficiency to mitigate future load growth; across all scenarios, the level of efficiency (at least 1.6%/yr through 2035) exceeds previous standards for program achievement (1.5%/yr).
- Significant investment in new wind and solar capacity (6-14 GW by 2045) as a source of carbon-free generation will be needed across all scenarios.
- Substantial investments in energy storage (2-9 GW by 2045) will help to facilitate integration of renewable resources while also helping to meet peak capacity needs;

© 2019 Energy and Environmental Economics, Inc.

- By 2045, Xcel's generation portfolio will rely predominantly on carbon-free resources to meet annual energy needs, while gas generation will help to meet resource adequacy needs but will operate infrequently.

The various strategies to achieve greenhouse gas reductions reflected in the scenarios examined in this study produce a wide range of portfolios and resulting cost outcomes. Table 5-1 highlights several key results that help distinguish the various scenarios from one another, including:

- **Levelized cost of carbon abatement ($/ton),** the unit cost of carbon abatement across the analysis horizon (2020-2045) measured relative to the Reference Case;
- **2045 rate impact (cents/kWh),** the change in the average retail rate measured relative to the Reference Case;
- **2045 effective RPS (%),** the level of renewable penetration achieved in each scenario expressed as a percentage of annual retail sales;
- **2045 renewable curtailment (%),** the level of curtailment experienced in 2045 due to the imbalance between variable resource availability and hourly demand;
- **2045 new storage capacity,** the cumulative total capacity of new storage resources added from 2020-2045 to enable renewable integration and help meet resource adequacy needs; and
- **2045 new gas capacity,** the cumulative total capacity of new gas resources added from 2020-2045 to meet residual resource adequacy needs as part of a least-cost portfolio.

Table 5-1. Key metrics for all scenarios

Scenario	Levelized Cost of Abatement ($/ton)	2045 Portfolio Metrics				
		Average Rate Impact (cents/kWh)	Effective RPS (%)[7]	Renewable Curtailment (%)	New Storage Capacity (MW)	New Gas Capacity (MW)
Scenario 1	$62	+1.2	112%	7%	3,032	2,293
Scenario 2	$25	+0.7	107%	6%	2,786	2,541
Scenario 3	$21	+0.7	107%	6%	2,484	2,708
Scenario 4	$69	+1.5	118%	9%	4,968	835
Scenario 5	$37	+1.2	110%	7%	5,636	835
Scenario 6	$40	+1.2	108%	6%	5,589	835
Scenario 7	$72	+1.8	121%	10%	8,346	—
Scenario 8	$47	+1.6	113%	7%	8,984	—
Scenario 9	$54	+1.7	112%	7%	8,885	—
Scenario 10	$54	+0.9	99%	6%	2,819	2,060
Scenario 11	$20	+0.6	93%	5%	2,484	2,275
Scenario 12	$17	+0.5	93%	4%	2,273	2,453
Scenario 13	$41	+0.6	75%	4%	2,434	1,711
Scenario 14	$13	+0.3	70%	3%	2,187	1,872
Scenario 15	$13	+0.3	70%	3%	1,867	2,081
Scenario 16	$71	+1.2	112%	7%	3,032	2,296
Scenario 17	$28	+0.7	107%	6%	2,786	2,541
Scenario 18	$22	+0.7	107%	6%	2,484	2,708
Scenario 19	$43	+0.7	78%	5%	3,484	835
Scenario 20	$16	+0.5	73%	4%	3,726	835

[7] Effective RPS levels that exceed 100% result from two factors: (1) the effective RPS is calculated based on retail sales, which is lower than total generation needed to serve load due to transmission & distribution losses; and (2) the total annual generation in the portfolio exceeds the Upper Midwest load and a portion of the excess is sold into the MISO market.

© 2019 Energy and Environmental Economics, Inc.

Scenario	Levelized Cost of Abatement ($/ton)	2045 Portfolio Metrics				
		Average Rate Impact (cents/kWh)	Effective RPS (%)[7]	Renewable Curtailment (%)	New Storage Capacity (MW)	New Gas Capacity (MW)
Scenario 21	$18	+0.5	73%	4%	3,499	835

The remainder of this section is dedicated to a detailed investigation into a specific subset of scenarios that illuminate tradeoffs among strategic choices of how to achieve long-term goals while containing costs to Xcel's customers and inform key questions on the nature of decarbonizing electricity, namely:

- What potential effect could an early exit from coal resources have upon the costs of meeting 2030 greenhouse gas goals?
- How would future restrictions upon Xcel's ability to invest in natural gas generation capacity to meet resource adequacy needs affect the cost of meeting greenhouse gas goals?
- What impact could extensions to the operating licenses of Xcel's existing nuclear plants have upon the costs of meeting long-term greenhouse gas goals?

Each question is investigated in depth in the subsequent three sections.

5.3 Scenario Analysis: Timing of Coal Exit

Xcel's coal resources are the most carbon-intensive source of generation in its portfolio. While Xcel has already committed to retire Sherco Units 1 & 2 (1.6 GW) in 2026 and 2023, respectively, retention of AS King and Sherco 3 through their current existing lifetimes (2037 and 2040, respectively) has direct implications upon the ability of the Upper Midwest system to achieve significant incremental carbon reductions by 2030. Thus, one of the key assumptions varied across scenarios in this study is the timing of their retirement, as acceleration of the closure of one or both plants prior to 2030 has a direct effect

upon the investments needed and consequent costs to achieve Xcel's interim milestones. This section compares the scenario results for three scenarios shown in Table 5-2.

Table 5-2. Scenarios examined to test impact of early coal retirements

ID	AS King	Sherco 3	Prairie Island	Monticello	New Gas?
0	**Planned ret**	**Planned ret**	**Not relicensed**	**Not relicensed**	**Yes**
1	Planned ret	Planned ret	Not relicensed	Not relicensed	Yes
2	**Early retirement**	Planned ret	Not relicensed	Not relicensed	Yes
3	**Early retirement**	**Early retirement**	Not relicensed	Not relicensed	Yes

5.3.1 PORTFOLIO RESULTS

Each of these scenarios achieves at least an 85% carbon reduction by 2030, but the range of approaches represented highlights the implications associated with retaining existing coal resources. Figure 5-5 and Figure 5-6 show the total installed capacity and annual generation mix associated with each of these three scenarios, along with the Reference Case.

© 2019 Energy and Environmental Economics, Inc.

Figure 5-5. 2030 snapshot: installed capacity (MW) for Scenarios 1, 2 & 3

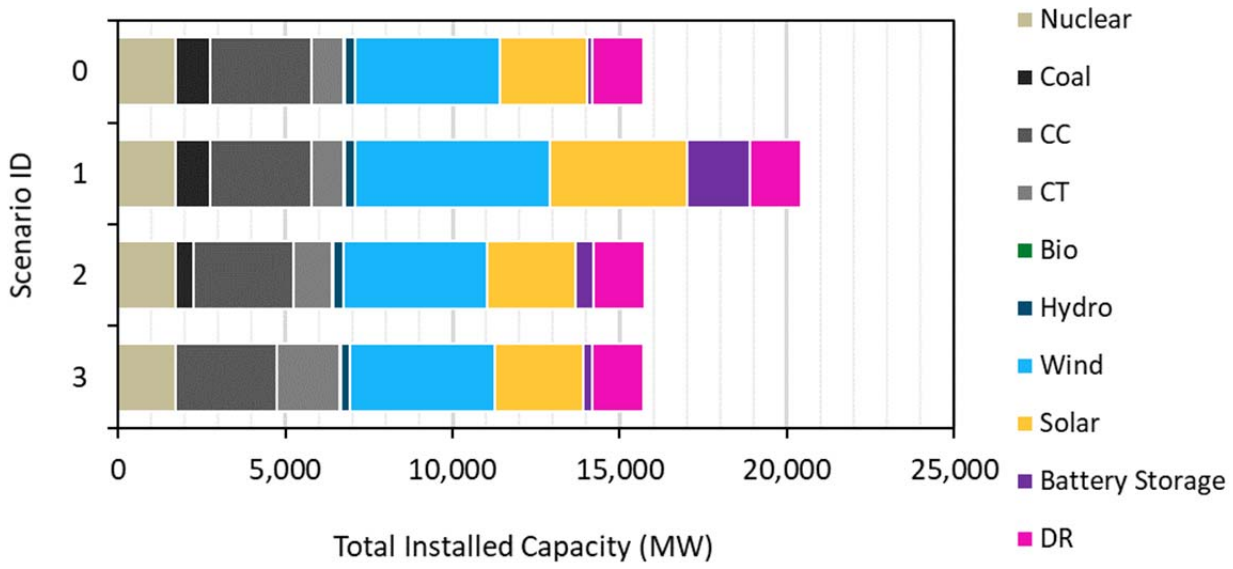

Figure 5-6. 2030 snapshot: annual generation (GWh) for Scenarios 1, 2 & 3

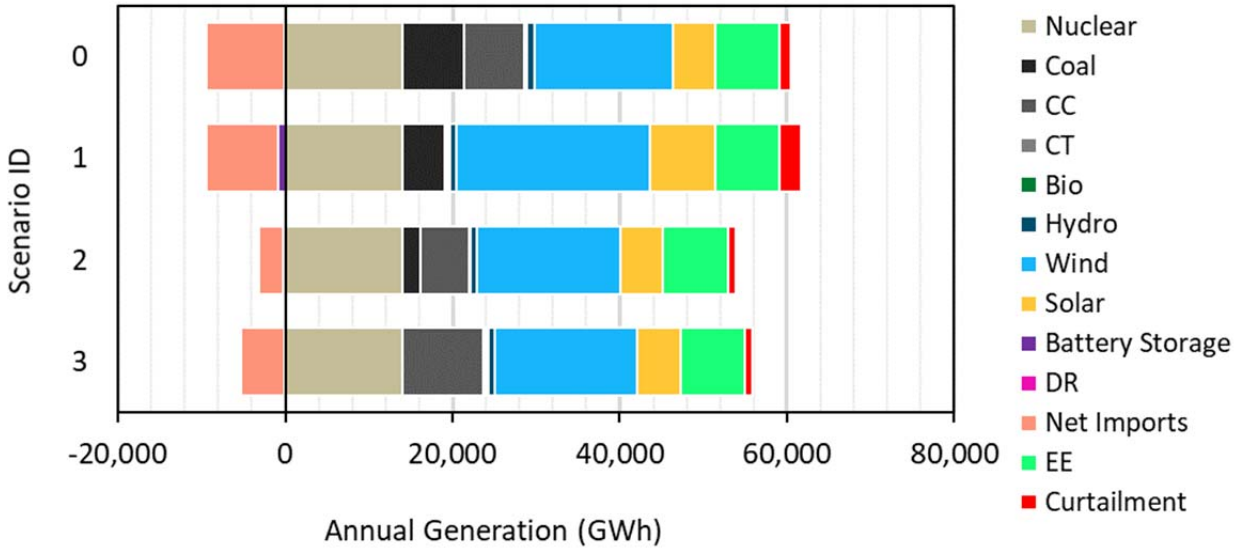


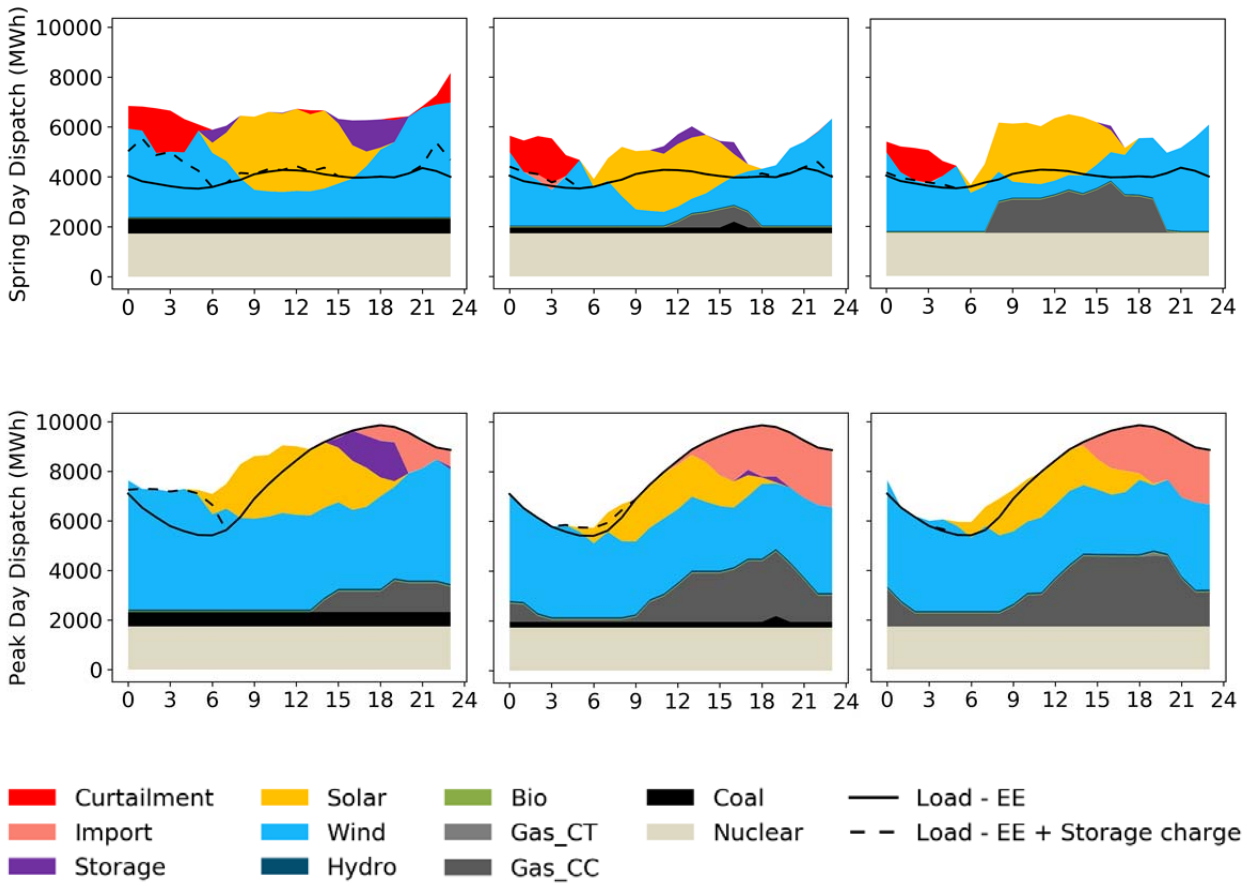
The contrast among portfolios informs several significant findings:

- Meeting Xcel's interim greenhouse gas goals while continuing to operate AS King and Sherco 3 will require very large investments in renewable generation and storage prior to 2030. Relative to the Reference Case, the corresponding carbon reduction scenario requires an additional 3 GW of wind and solar generation and an additional 1.9 GW of energy storage by 2030; these investments are needed to displace flexible gas generation from Xcel's portfolio. The level of renewables needed results in an "effective" renewable penetration of 74% by 2030—significant enough that storage investments are needed to help balance its variability.
- Scenarios that close one or both of Xcel's remaining coal plants by 2030 can achieve Xcel's 2030 carbon goals without significant need for carbon-free resources beyond those already specified in the Reference Case; however, additional investment in gas or other resources will be needed to meet resource adequacy needs absent the contributions of AS King and Sherco 3 to Xcel's resource adequacy needs.

The contrast among these portfolios is even more stark on an hourly basis. Figure 5-7 compares snapshots of hourly operations on two representative days: one in the spring, during which relatively low loads and high levels of renewable production tend to result in periodic surpluses of renewable generation; and one in the summer, when peaking loads require the full capability of Xcel's fleet to meet loads throughout the day.

© 2019 Energy and Environmental Economics, Inc.

Figure 5-7. Dispatch patterns for Scenarios 1, 2, and 3 (left to right) on a representative spring day and peak summer day



The hourly operations in the representative spring day reveal how significant the renewable integration challenges associated with the scenarios that retain both coal plants through 2030 would be: the level of carbon-free resource production during the midday periods in 2030 exceeds the hourly demand of the Xcel system; the renewable integration challenge is compounded by the lack of flexibility of coal resources to accommodate their output; and despite the capability of energy storage to absorb some surplus and the ability to sell a relatively large quantity of surplus into the MISO market, 7% of available renewable generation is curtailed in 2030. This level of curtailment is substantially larger than the level

observed in scenarios that reduce reliance on coal (and, as a result, face a more manageable burden of renewable integration), which yield levels of curtailment in 2030 of approximately 4%.

5.3.2 COST IMPACTS

Two key cost metrics are used throughout this study to compare the impacts of various scenarios: (1) the **levelized cost of carbon abatement** and (2) the **annual rate impact** in five- year increments. The two metrics are intended to be complementary: the former serves as a useful means of summarizing the impacts associated with a scenario in a single metric, but obscures the some of the interesting dynamics related to the timing associated with those costs; the latter provides more resolution on how costs are incurred by Xcel's customers through time but makes one-to-one comparisons across scenarios more difficult.

Table 5-3 shows the levelized cost metric for these three scenarios. Scenario 1, which preserves both coal plants through their current existing lives, has a cost of carbon abatement significantly higher than either of the scenarios; this is driven by the large amount of infrastructure investment needed to meet near-term greenhouse gas goals while continuing to operate the coal plants through their current lifetimes. The levelized costs of abatement in Scenarios 2 and 3 are much closer—generally indicating that accelerating one retirement provides very large benefits to Xcel's customers in the context of meeting 2030 goals, while the accelerating the retirement of the second plant provides some additional benefit, though not as much as the first.

Table 5-3. Levelized costs of carbon abatement across scenarios.

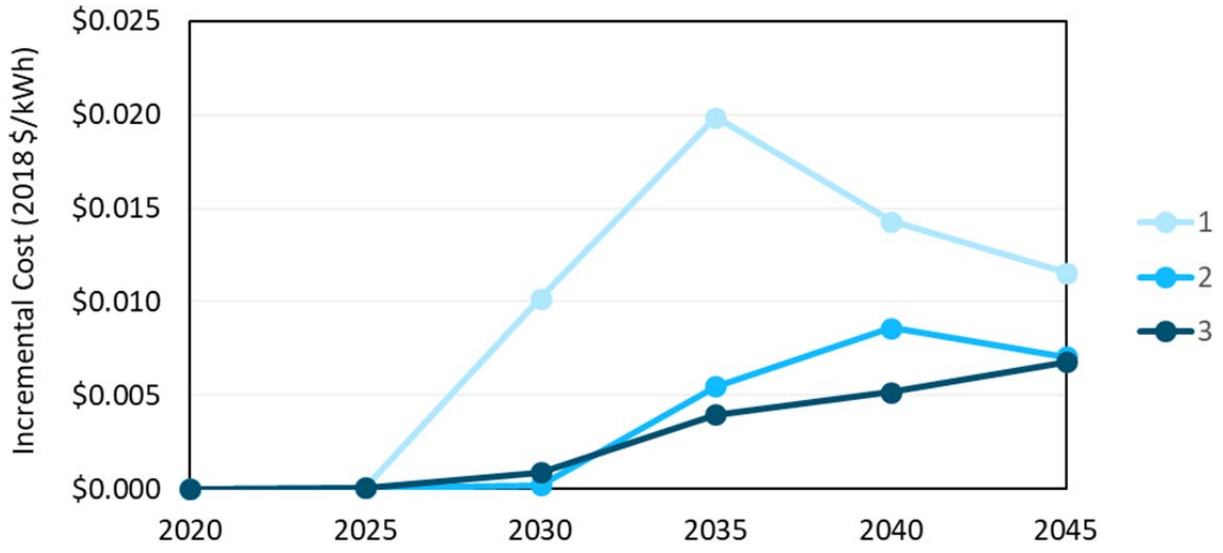
Scenario	AS King Retirement	Sherco 3 Retirement	Levelized Cost of Abatement ($/ton)
Scenario 1	2037	2040	$62
Scenario 2	pre-2030	2040	$25

© 2019 Energy and Environmental Economics, Inc.

Scenario	AS King Retirement	Sherco 3 Retirement	Levelized Cost of Abatement ($/ton)
Scenario 3	pre-2030	pre-2030	$21

Figure 5-8 shows how the incremental costs (measured relative to the Reference Case) would be borne by ratepayers over time. In Scenario 1, the need for significant investments in renewables in the 2030 begins to drive substantial increases in rates; this effect is exacerbated by 2035 due to the assumed retirement of Xcel's nuclear plants with in this five-year window; only after 2035 does the incremental cost associated with Scenario 1 begin to drop as AS King and Sherco 3 reach the ends of their useful lives. In contrast, both Scenarios 2 and 3 meet the 2030 emissions reductions goals with minimal impact on rates, and lead to moderate impacts in the long run as additional renewable and storage resources are added to displace gas and help to replace retiring nuclear plants. Scenarios 2 and 3 do show some separation in rate impact in 2035 and 2040; Scenario 3, having retired both coal plants early, exhibits the lowest impact on rates associated with the more stringent greenhouse gas goals imposed in this decade.

Figure 5-8. Annual rate impact (relative to Reference Case) associated with Scenarios 1-3

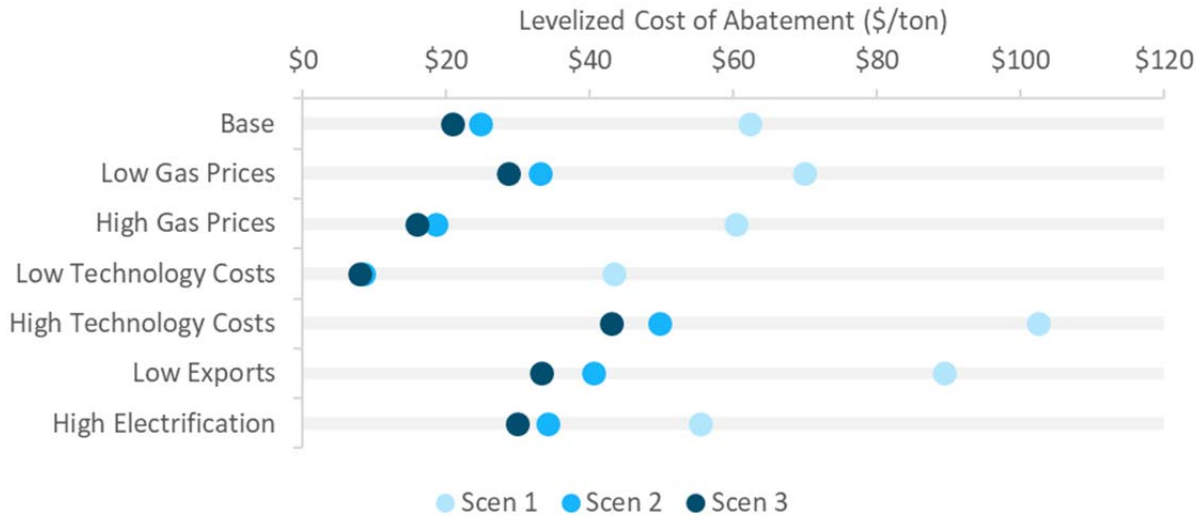


5.3.3 SENSITIVITY ANALYSIS

Sensitivity analysis on key uncertain inputs helps to highlight the level of confidence in the directional results that these results point towards. The four categories of sensitivity tested—gas prices, future technology costs, levels of electrification load, and the ability to export to the MISO market—lend further support to the conclusion that an accelerated shutdown of some combination of AS King and Sherco 3 will result in a more cost-effective pathway to achieving 2030 emissions goals.

Figure 5-9 summarizes the impact of the range of sensitivities on the levelized cost of abatement for the scenarios that vary the timing of Xcel's coal exit.

Figure 5-9. Sensitivity analysis on levelized cost of abatement across scenarios



Several findings are apparent from the range of sensitivities analyzed:

+ Most importantly, across all sources of uncertainty considered in this study, no alternative assumptions would alter the directional relationship among the scenarios examined: across all

© 2019 Energy and Environmental Economics, Inc.

sensitivities, a long-term strategy that maintains coal assets through their current existing lifetimes results in the highest costs to meet interim and long-term reduction goals.

+ The cost of abatement is relatively insensitive to natural gas prices. Lower gas prices will tend to increase the costs of achieving carbon reductions across the analysis horizon. Because the Reference Case portfolio relies more heavily on gas across the horizon than any of the carbon reduction scenarios, lower gas prices result in a higher cost premium for the new sources of carbon-free generation. However, the overall exposure to gas price uncertainty is relatively low.

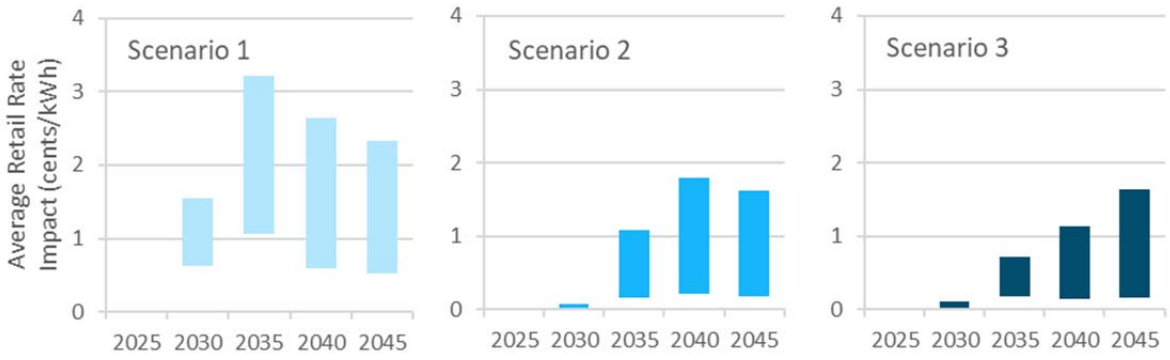
+ The scenarios do notably exhibit a wider range of sensitivity to future technology costs for renewables and storage than to gas prices: higher technology costs increase the cost of abatement by 50-60%; lower technology costs reduce the cost of abatement by 30-40%. The sensitivity to future costs highlights a changing paradigm for utilities whose long-term planning exercises focus not only on cost but on risk as well: as exposure to fossil fuel prices decreases, traditional sources of uncertainty (e.g. natural gas prices) will become less significant drivers of uncertainty than forecasts of technological evolution and innovation (e.g. assumptions on the future rate of decline of storage costs).

+ A common trend in the scenarios presented is reliance on market interactions to meet load in times of low renewable output, and to generate revenue by selling surplus renewable energy to offset a portion of its costs. However, if surrounding jurisdictions in MISO also move towards decarbonization, the ability to export in the times of overgeneration may be limited; assuming similar investment in low-carbon technologies to decarbonize. Compared to the Base Case assumptions, the level of curtailment is between 2.5 to 2.8 times greater for these sensitivities in 2045. The results suggest that in a world in which the region collectively pursues aggressive decarbonization, the cost of carbon abatement will increase.

+ Carbon abatement cost exhibits limited sensitivity to future load levels: while additional investment in carbon-free resources and complementary investments for reliability will be needed, the associated incremental costs are spread across a larger base of retail sales such that the overall cost of abatement does not increase substantially.

The sensitivities conducted also provide useful information on how the costs of achieving long-term goals might vary through time in any single scenario. Figure 5-10 shows the range of costs, expressed as the impact on average retail rates, through time in each scenario. This perspective highlights the fact that not only is a strategy that preserves both remaining coal plants through their remaining lives a higher cost pathway to low carbon goals, but it also has a higher level of risk: the range of potential cost outcomes for this portfolio is considerably larger than its counterparts due to the uncertain costs of the large amounts of renewable and storage investment needed to meet near-term carbon goals with both coal plants on line. Not only are costs lower in Scenarios 2 & 3, but they are generally more certain as well.

Figure 5-10. Year-by-year range of cost impacts for Scenarios 1, 2 & 3 across all sensitivities



5.3.4 IMPLICATIONS

The contrast among scenarios that retain AS King and Sherco 3 through their remaining useful lives and those that accelerate their shutdown to facilitate achievement of interim greenhouse gas goals provides insight into the impact of each potential decision. This analysis suggests that retiring the first coal plant reduces the necessary overbuild of renewables to meet Xcel's near-term climate goals. There is a significant decrease in levelized cost of carbon abatement by retiring AS King early. While the

© 2019 Energy and Environmental Economics, Inc.

subsequent early retirement of Sherco 3 also reduces the levelized cost of abatement, the benefit is smaller than that of the first retirement.

5.4 Scenario Analysis: Limits on New Gas Infrastructure

Up to 7 GW of existing firm capacity in Xcel's Upper Midwest system may be retired by 2045. While significant investments in renewable energy and battery storage will be needed to meet Xcel's long-term carbon reduction target, the question of how much (if any) additional fossil-based firm capacity is necessary to ensure a reliable system cost-effectively remains. The reliability analysis described in Section 4 showed the sizeable investments in renewables and storage needed to serve load in the absence of any firm generation resources, indicating that retention of some level gas capacity in the Upper Midwest system that operates at low capacity factors would help meet Xcel's goals. This section investigates the cost implications of a range of limitations on new gas investments. One case (Scenario 6) restricts new investment to allow for only the development of a new combined cycle plant at the Sherco site; another (Scenario 9) prohibits any new gas capacity. The subset of scenarios examined in this section also assume that the retirements of the Sherco 3 and King plants are accelerated to pre-2030, as this was identified above as a key component of a least-cost strategy to meet near-term carbon reduction objectives. Table 5-4 shows the scenarios examined in this section.

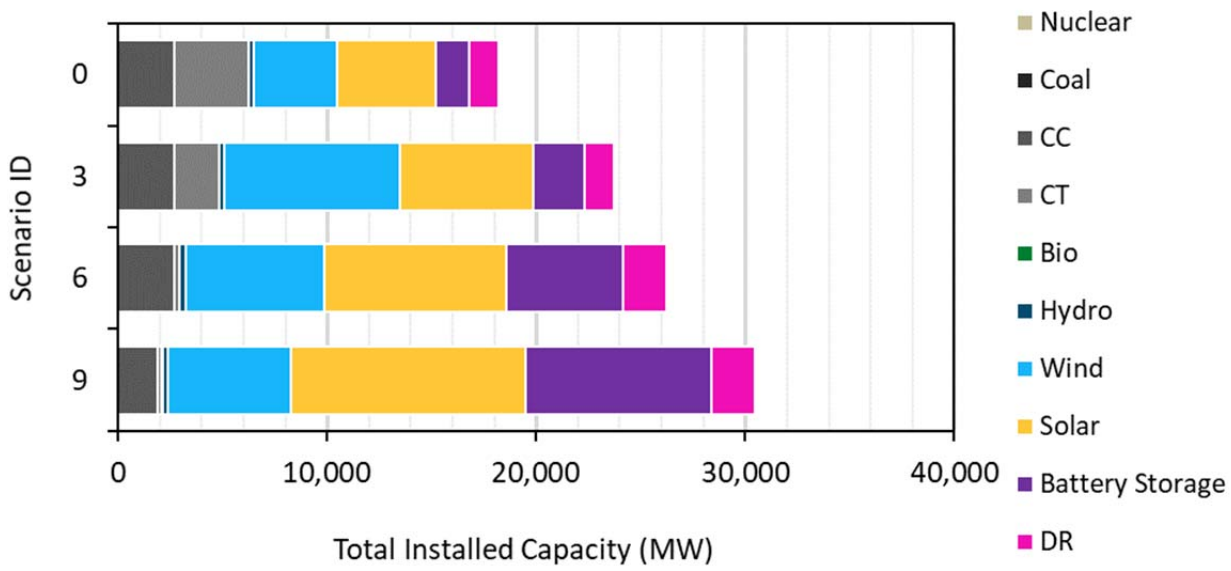
Table 5-4. Scenarios examined to test impacts of new gas prohibition

ID	AS King	Sherco 3	Prairie Island	Monticello	New Gas?
0	**Planned ret**	**Planned ret**	**Not relicensed**	**Not relicensed**	**Yes**
3	**Early retirement**	**Early retirement**	Not relicensed	Not relicensed	Yes
6	**Early retirement**	**Early retirement**	Not relicensed	Not relicensed	**Sherco CC only**
9	**Early retirement**	**Early retirement**	Not relicensed	Not relicensed	**None**

5.4.1 PORTFOLIO RESULTS

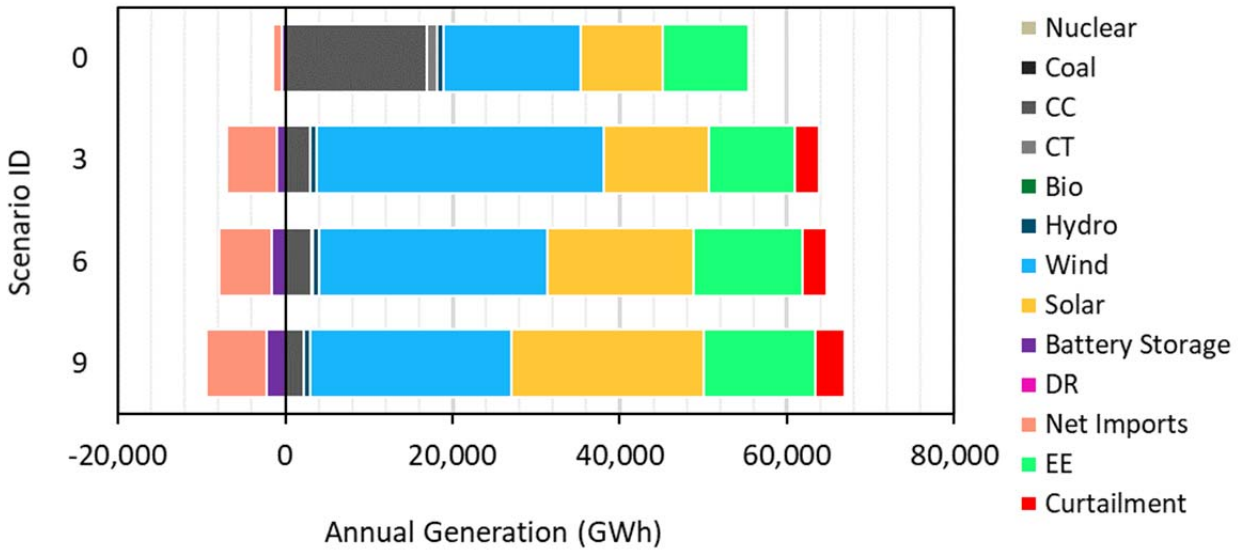
These scenarios all achieve at least a 95% carbon reduction by 2045, but the range of new infrastructure investment shows the impact of potential restrictions on new gas investments. Figure 5-11 and Figure 5-12 show the total installed capacity and annual generation mix associated with each of these three scenarios, along with the Reference Case.

Figure 5-11. 2045 snapshot: installed capacity (MW) for Scenarios 3, 6 & 9



© 2019 Energy and Environmental Economics, Inc.

Figure 5-12. 2045 snapshot: annual generation (GWh) for Scenarios 3, 6 & 9

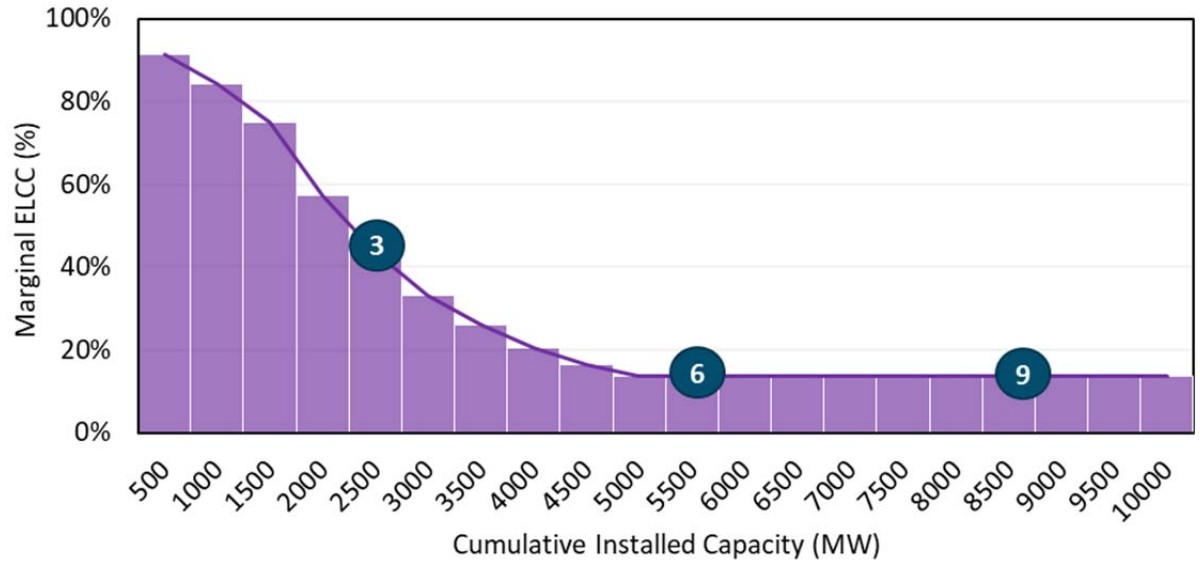


Comparing the portfolios informs several significant findings:

- The amount of capacity needed to meet reliability goals with limits on new gas resources is substantially higher than in scenarios that do not restrict new gas resources. Most of this additional capacity comes in the form of battery storage, but also includes some increases in high-cost tranches of efficiency and DR. The restrictions on gas resources in Scenarios 6 and 9 induce a limited increase in renewable capacity, as well as a shift from wind to solar, whose diurnal production pattern enables more frequent cycling of energy storage resources.
- Despite significant difference in capacity, the three scenarios result in very similar levels of annual gas generation (and corresponding greenhouse gas emissions). Despite the comparatively large buildout of CTs in Scenario 3, the total energy provided by those units in 2045 is insignificant, as they are built to meet resource adequacy needs but run infrequently. New gas units are valuable resources for preserving reliability and help reduce the costs of serving load in a largely decarbonized world. Scenarios 6 and 9 require a level of battery storage buildout that is much higher than any other scenario – 5.6 GW and 8.9 GW, respectively. As

detailed in Section 4, the ELCC of battery storage declines over time. Figure 5-13 shows where the scenarios studied in this section fall on the ELCC curve.

Figure 5-13. Marginal ELCC for storage resources in Scenarios 3, 6, and 9 in 2045



The level of battery capacity on the system in Scenarios 6 and 9 reach the minimum marginal ELCC contribution in the curve. To put this in perspective, the last 3.5 GW of batteries in scenario 9 receive about the same capacity credit as 500 MW of new combustion turbines. New CT capacity is typically used for reliability purposes and infrequently dispatched, as depicted for Scenario 3 in Figure 5-12, so giving preference to battery storage to provide these services seems an improper assignment of purpose when high levels of storage are already on the system.

5.4.2 COST IMPACTS

Table 5-5 shows the levelized cost of carbon abatement for these three scenarios. Scenario 3, seen previously, has the lowest cost of carbon abatement, while Scenarios 6 and 9 are almost two and three times more expensive, respectively. This premium represents the cost of meeting reliability needs with a

© 2019 Energy and Environmental Economics, Inc.

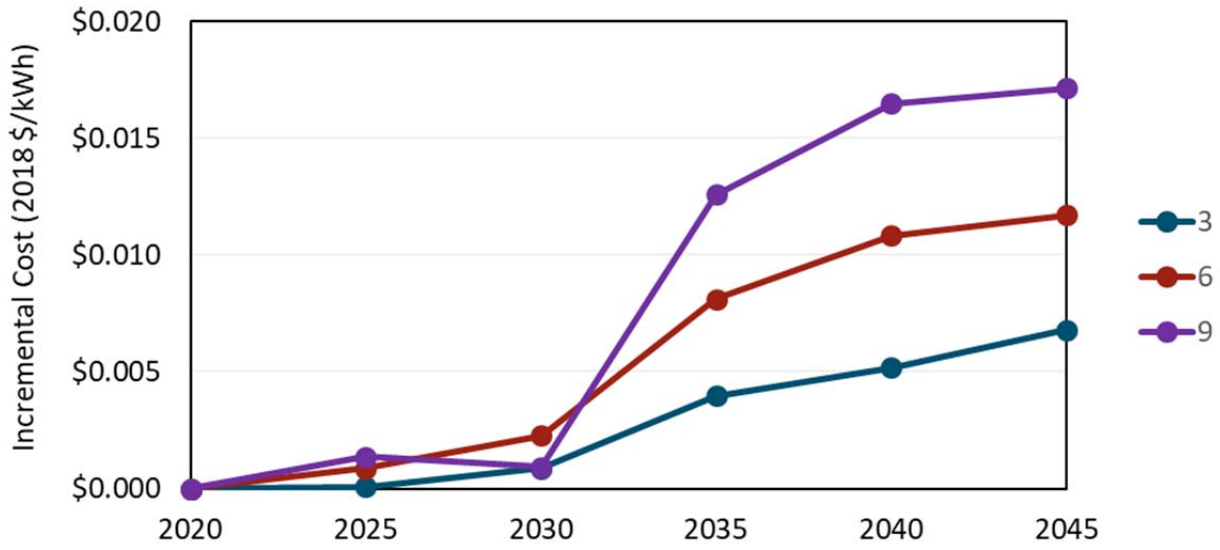
greater share of batteries, DR, EE, and renewables, given that each of these scenarios has the exact same carbon emissions in 2045.

Table 5-5. Levelized cost of carbon abatement across scenarios

Scenario	Gas Build Restriction	Levelized Cost of Abatement ($/ton)
Scenario 3	Unrestricted	$21
Scenario 6	Only Sherco CC	$40
Scenario 9	No New Gas	$54

Figure 5-14 highlights the annual rate impact over time, as shown in the previous results section. While the near-term impact is relatively small, the impacts grow substantially beyond 2030 due to continued load growth and the retirement of Xcel's existing nuclear plants, with the trend mirroring the trend in levelized cost of carbon abatement. The investment in capacity for reliability that would otherwise be cheap gas CTs increases 2045 rates by an additional $0.005/kWh and $0.010/kWh for Scenarios 6 and 9, respectively, compared to Scenario 3.

Figure 5-14. Annual rate impact (relative to Reference Case) associated with Scenarios 3, 6, and 9

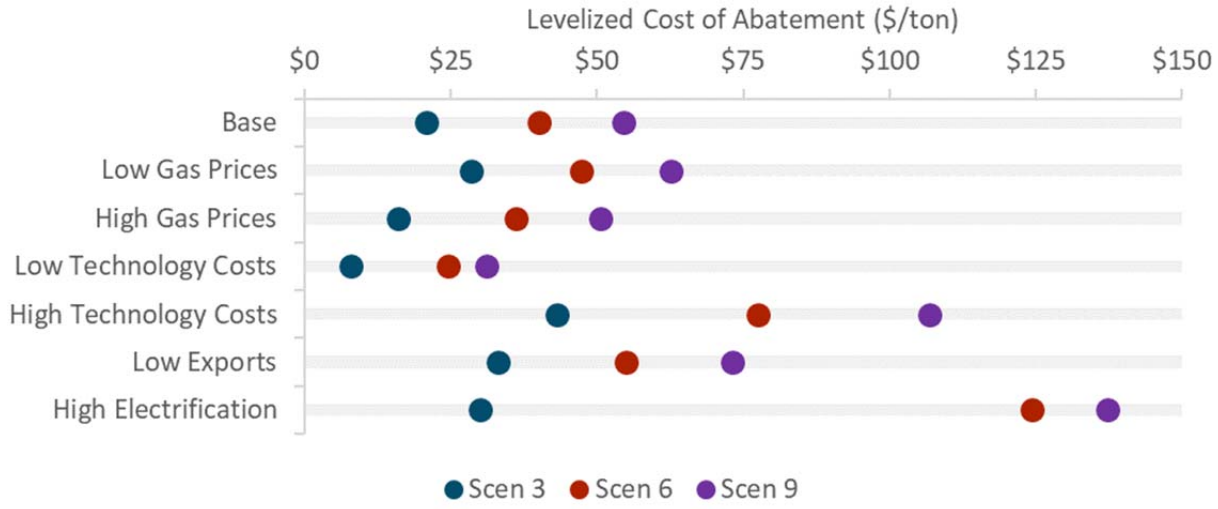


5.4.3 SENSITIVITY ANALYSIS

The three sensitivity categories—gas prices, future technology costs, and levels of electrification load—again support the conclusion that prohibiting new gas units is not a cost-effective way to reach Xcel's 2045 emissions goal. Figure 5-15 shows how each sensitivity affects the levelized cost of abatement for these scenarios.

© 2019 Energy and Environmental Economics, Inc.

Figure 5-15. Sensitivity analysis on levelized cost of abatement across scenarios



The following are key takeaways from the sensitivities for these scenarios:

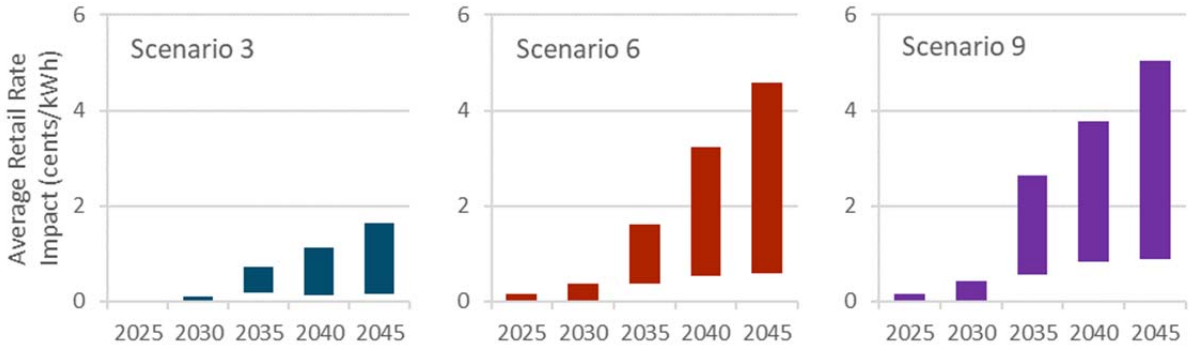
- As in the previous set of scenarios, none of the sensitivities alter the directional relationship among the scenarios examined: across all sensitivities, a long-term strategy that includes new gas investment ensures a cost-effective way to achieving Xcel's carbon reduction goals.
- The cost of abatement is, again, relatively insensitive to natural gas prices. Lower gas prices will tend to increase the costs of achieving carbon reductions across the analysis horizon due to the Reference Case portfolio relying more heavily on gas, while higher gas prices decrease the levelized cost of carbon abatement slightly.
- Because disallowing new gas build requires more investment in renewable energy and battery storage, the sensitivities around the costs of renewables and storage show a larger impact than gas prices. Lower technology costs reduce the levelized cost of abatement, but the difference between Scenario 3 and 6 still stays nearly the same. Higher technology costs almost double the abatement cost differences between the cases.

- Eliminating market revenues from exporting beyond 2030 shifts levelized costs of abatement upward, but the directional relationship between scenarios is preserved. Curtailment in these sensitivities is, again, over double the amount found using the Base Case assumptions in 2045.
- In a world with higher loads from electrification, prohibiting new gas buildout will have even greater implications. The overbuild seen in Scenarios 6 and 9 increases substantially in this sensitivity and is reflected by the extremely high cost of carbon abatement.

The range of impacts associated with individual scenarios provides another useful perspective on the potential consequences and implications of choosing a pathway towards decarbonization that prohibits new natural gas investments (see Figure 5-16). These scenarios (Scenarios 6 & 9) generally exhibit a wider range of cost outcomes than scenarios that allow new gas investments to contribute to reliability needs (here, Scenario 3). This range is driven by two factors. First, scenarios that prohibit new gas investment will require much larger investments in battery storage to meet reliability needs; future costs of battery storage are inherently highly uncertain. Second, the cost of meeting reliability needs in a high electrification future without new investments in natural gas proves to be considerably more challenging and costly than under the Base Case assumptions. The substantial increase in load also increases the level of resources needed to meet future resource adequacy needs; meeting all these future needs with energy storage and renewables will prove costly due to the inherent limits on their contributions to resource adequacy.

© 2019 Energy and Environmental Economics, Inc.

Figure 5-16. Year-by-year range of cost impacts for Scenarios 3, 6 & 9 across all sensitivities



5.4.4 IMPLICATIONS

This comparison of scenarios highlights the value of investments in new natural gas resources to enable achievement of deep carbon reductions while meeting reliability goals and minimizing costs. These gas investments—with the exception of the Sherco CC, all combustion turbines—provide a low-cost option to meet reliability standards but would operate rarely. While combinations of renewables, battery storage, DR, and EE, in conjunction with the remaining gas fleet in the Upper Midwest system, can serve load reliably, pursuing this pathway while excluding natural gas as an option is likely to contribute to significantly higher cost outcomes.

5.5 Scenario Analysis: Nuclear Relicensing

Xcel's two nuclear plants facilities, Monticello and Prairie Island, represent over 1.7 GW of firm capacity and have licenses that expire shortly after 2030. As depicted in the previous section, retaining some level of conventional firm capacity will help Xcel meet its long-term carbon reduction goal in a cost-effective way; the relicensing of Xcel's nuclear plants provides one possible option to meet a portion of that need. In this section, the value Xcel's nuclear fleet is examined by testing different combinations of

relicensing Xcel's nuclear fleet. Keeping some level of nuclear capacity online should reduce the need for investments to meet carbon goals (primarily renewables, efficiency) and to ensure a reliable system (primarily storage, gas, and DR). The scenarios analyzed in this section are shown in Table 5-6.

Table 5-6. Scenarios examined to test impact of nuclear relicensing

ID	AS King	Sherco 3	Prairie Island	Monticello	New Gas?
0	**Planned ret**	**Planned ret**	**Not relicensed**	**Not relicensed**	**Yes**
3	**Early retirement**	**Early retirement**	Not relicensed	Not relicensed	Yes
12	**Early retirement**	**Early retirement**	Not relicensed	**20-yr relicense**	Yes
15	**Early retirement**	**Early retirement**	**20-yr relicense**	**20-yr relicense**	Yes

5.5.1 PORTFOLIO RESULTS

The scenarios in this section again achieve a 95% reduction in carbon emissions in 2045. The installed capacity and annual generation, shown in Figure 5-17 and Figure 5-18, highlight the different strategies available to meet the long-term goal.

© 2019 Energy and Environmental Economics, Inc.

Figure 5-17. 2045 snapshot: installed capacity (MW) for Scenarios 3, 12 & 15

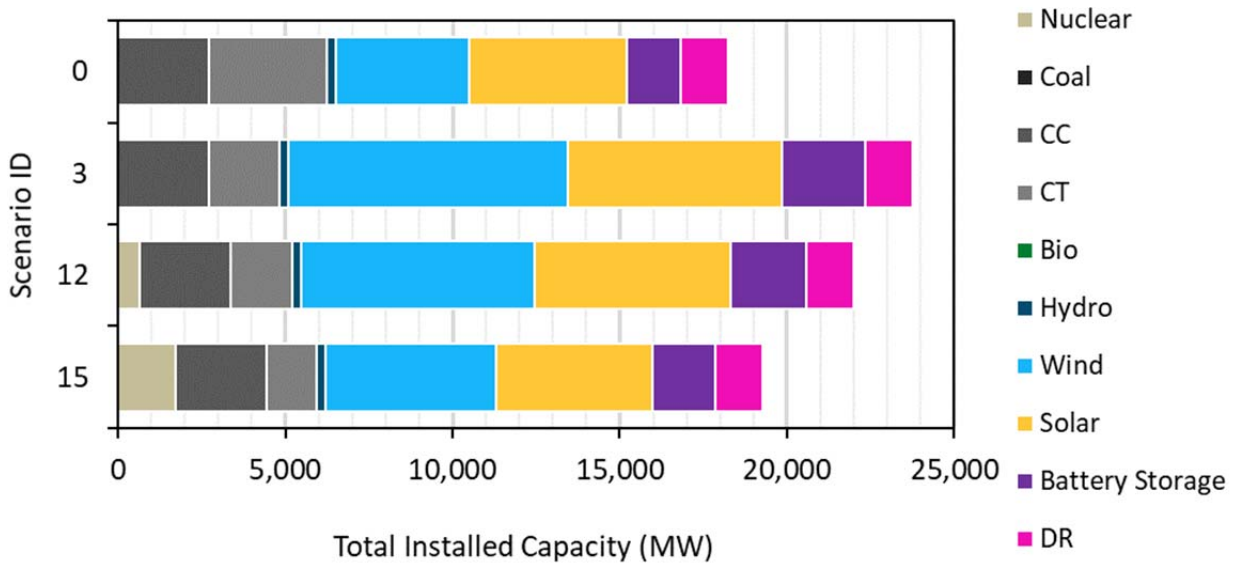


Figure 5-18. 2045 snapshot: annual generation (GWh) for Scenarios 3, 12 & 15

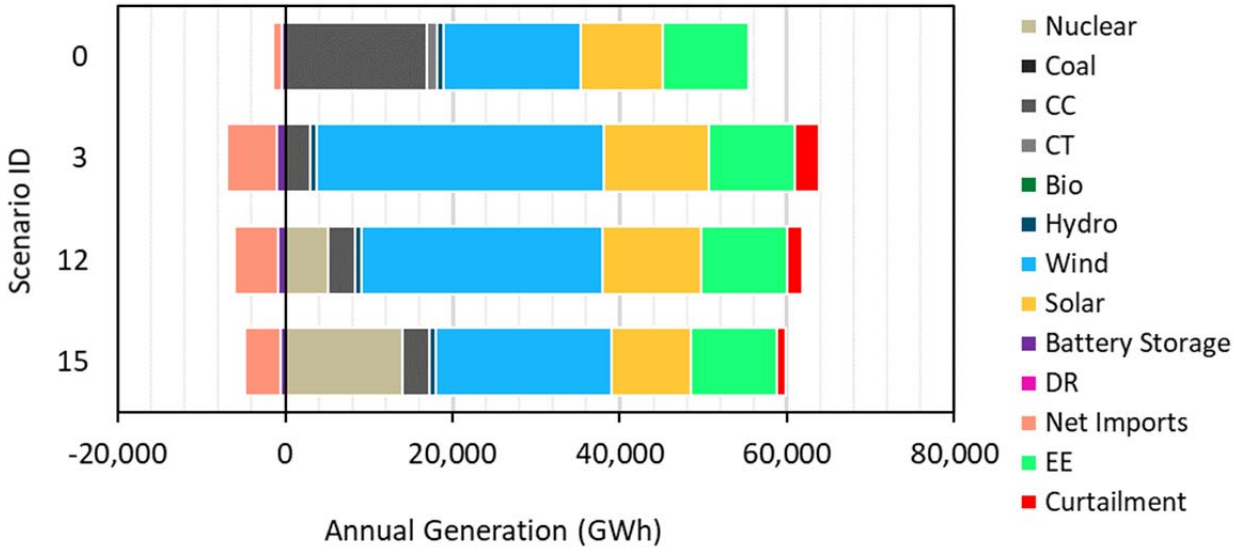


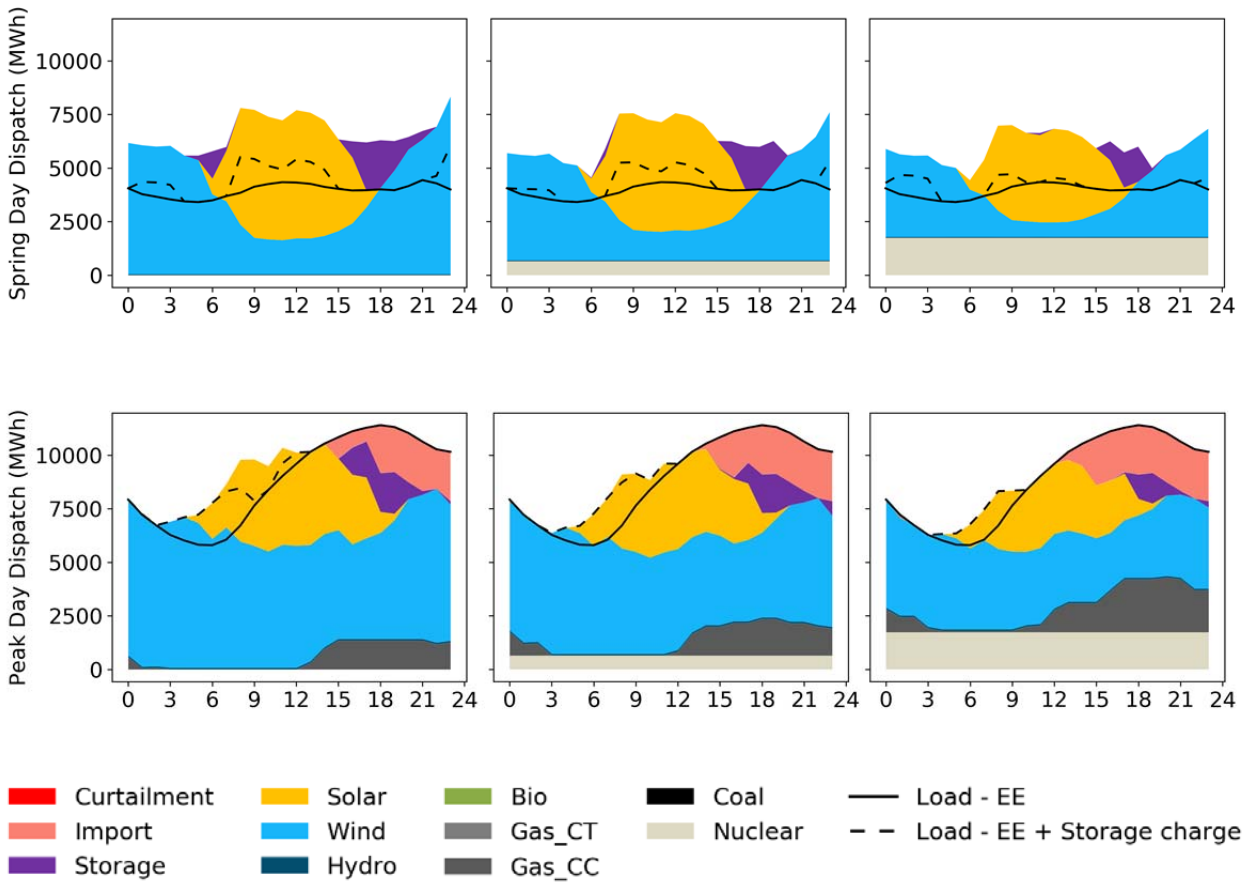
The key differences between these scenarios are as follows:

- Each incremental nuclear relicense significantly reduces investment in renewables, storage, and gas capacity. Relicensing a single plant (Monticello) reduces the amount of investment in new resources needed to meet the target by roughly 2,500 MW (2,000 MW of renewables, 200 MW gas, and 200 MW storage). Relicensing Prairie Island avoids an additional 5,000 MW of renewables and over 600 MW of both gas and storage. The baseload and carbon-free attributes of nuclear energy reduces the renewable overbuild needed in a low-carbon world.
- The relicensing of the nuclear plants reduces each portfolio's reliance on renewables as the primary source of carbon-free energy, and, in doing so, provides a valuable source of diversity that enables more efficient balancing of loads and resources. Each level of nuclear relicensing reduces the amount of renewable overgeneration that must be curtailed to manage periods of surplus renewable availability. In 2045, curtailment levels of 6% in Scenario 3 are reduced to 4% in Scenario 12 and then to 3% in Scenario 15. An Upper Midwest system with more nuclear relicensed thereby enables more efficient utilization of renewables.

The operations in each of the scenarios are shown for the typical spring and peak days in Figure 5-19.

© 2019 Energy and Environmental Economics, Inc.

Figure 5-19. Dispatch patterns for Scenarios 3, 12, and 15 (left to right)



On the spring day, Scenarios 12 and 15 replace wind generation with nuclear energy almost one-to-one, and the renewable overgeneration, ultimately sold to the market, persists. The only behavior noticeably different is that of the battery capacity on the system, which cycles more frequently when less nuclear energy is available; often to sell to the market. That general trend also carries over to the peak day dispatch; but, instead of charging to sell to the market later in the day, the batteries charge up on renewable overgeneration to meet the evening peak. With less battery capacity and renewable

overgeneration in Scenarios 12 and 15, a larger portion of the peak load is met with imports and Upper Midwest gas.

5.5.2 COST IMPACTS

Each incremental relicensing of Xcel's nuclear plants reduces the levelized cost of carbon abatement by $4/ton compared to Scenario 3, as shown in Table 5-7. The trend is indicative of the avoided investments in renewables and batteries; the alternative to the firm, carbon-free capacity that nuclear energy provides.

Table 5-7. Levelized cost of carbon abatement across scenarios

Scenario	Monticello Relicensing	Prairie Island Relicensing	Levelized Cost of Abatement ($/ton)
Scenario 3	No	No	$21
Scenario 12	Yes	No	$17
Scenario 15	Yes	Yes	$13

Figure 5-20 shows the corresponding impact on average retail rates. The scenarios diverge beginning in 2035, when various levels of nuclear remain online for these scenarios. In that year, relicensing one nuclear plant reduces rates while relicensing both increases rates, compared to Scenario 3. Because the carbon goal in 2035 is not as stringent, relicensing the second unit exceeds the target and a premium is paid to do so. However, the following years show the value of relicensing both nuclear plants, as more renewable and battery investment is avoided. By 2045, rates are $0.004/kWh cheaper than Scenario 3, as opposed Scenario 12 which is only $0.001/kWh cheaper.

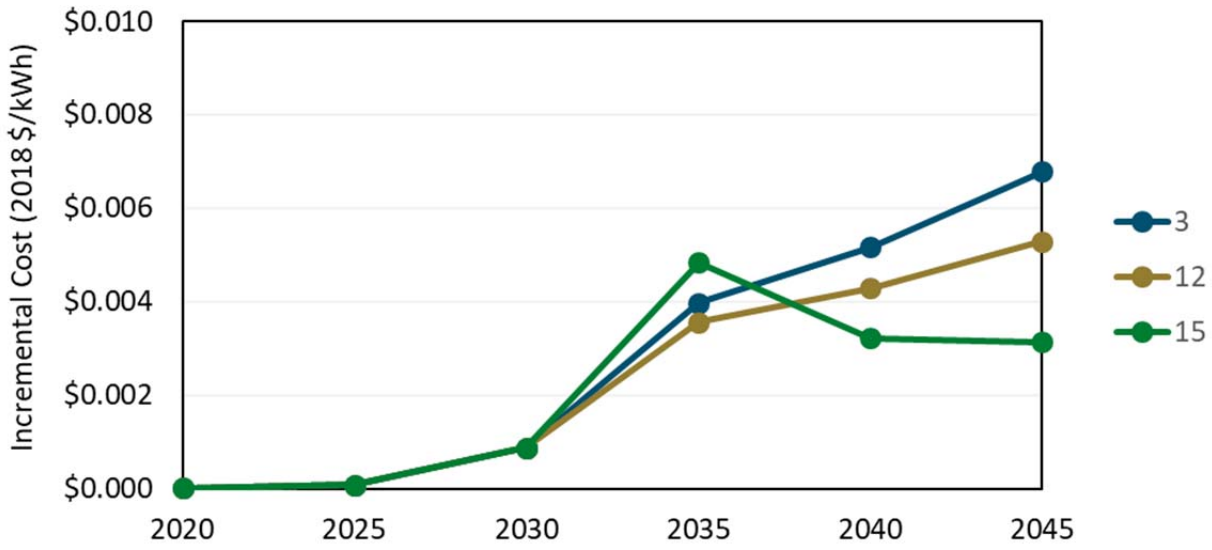
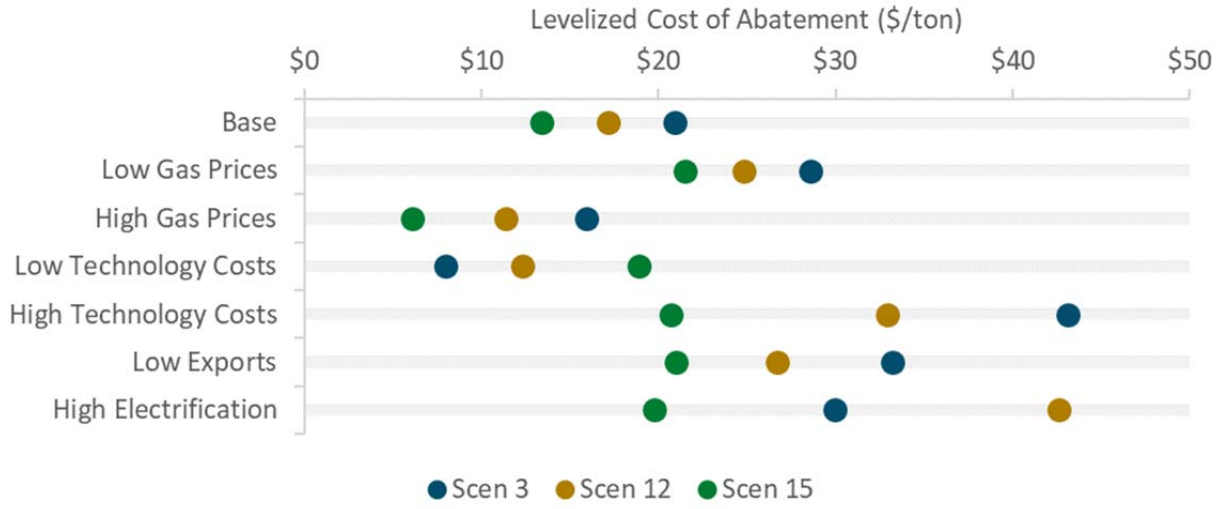
Figure 5-20. Annual rate impact (relative to Reference Case) associated with Scenarios 3, 12, and 15



5.5.3 SENSITIVITY ANALYSIS

For this set of cases, all but one sensitivity convey the same general takeaways as the Base Case assumptions. Figure 5-21 below shows the affects each sensitivity has on the levelized cost of carbon abatement.

Figure 5-21. Sensitivity analysis on levelized cost of abatement across scenarios



These are the takeaways from this sensitivity analysis:

- The High and Low Gas Price sensitivities again do not affect the general relationships among this set of scenarios. Lower gas prices increase the levelized cost of carbon abatement while higher gas prices decrease the levelized cost of abatement. Overall, the shift up or down for each scenario stays consistent with shifts for previously discussed scenarios.
- The Low Technology Cost sensitivity for this set of scenarios is the only sensitivity that changes the directional relationship among scenarios: under a low technology cost future, relicensing Xcel's nuclear plants may result in a higher cost to meet carbon reduction goals than replacement with a combination of wind, solar, storage, and gas. On the other hand, the High Technology Cost sensitivity has the opposite effect of the low technology sensitivity; making relicensing appear an even more cost-effective strategy to meeting long-term carbon goals.
- A long-term limit on exports beyond 2030 increases 2045 curtailment for Scenarios 12 and 15 by substantial amounts—from levels between 3 and 4% to 13%. the largest increases among this

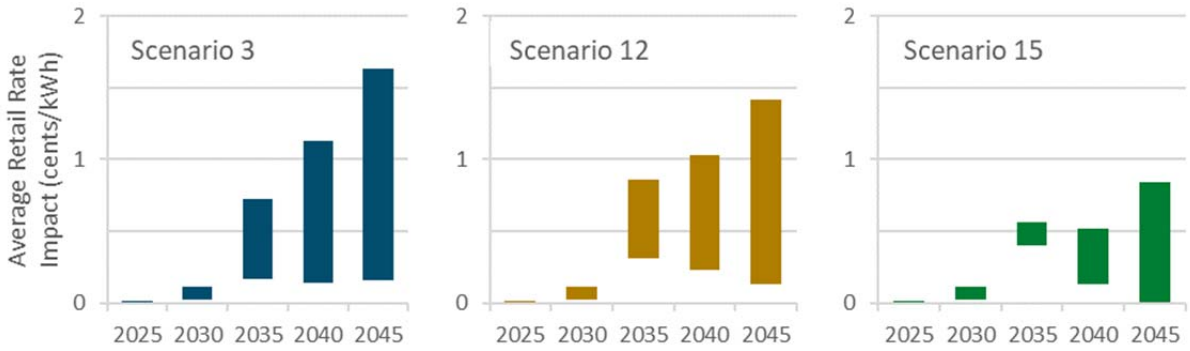
© 2019 Energy and Environmental Economics, Inc.

set of sensitivities. Despite the significant increase in curtailment, the levelized cost of carbon abatement increases similarly to the other low export scenarios.

+ For the High Electrification sensitivity, the costs only shift upwards, as seen previously. However, the magnitude of the shift is smallest for these scenarios compared to other High Electrification sensitivities.

Figure 5-22 shows the range of costs to Xcel's customers resulting from the range of sensitivities examined. In general, these results highlight a narrower band of uncertainty in future costs that results from scenarios that pursue nuclear relicensing. One characteristic of all three scenarios shown here, though (which are generally among the lowest cost options examined in this study) is a growing uncertainty with respect to cost over time. This crescendo of uncertainty reflects the reality that the cost of decarbonizing electricity in the long run remains inherently uncertain, and while this study highlights promising options and opportunities to mitigate this cost, precise measurement of how that will impact Xcel's customers is ultimately difficult to predict.

Figure 5-22. Year-by-year range of cost impacts for Scenarios 3, 12 & 15 across all sensitivities



5.5.4 IMPLICATIONS

The comparisons between scenarios illustrate the substantial value of Xcel's nuclear plants as a firm, carbon-free resources. The analysis shows benefits to Xcel resulting from a relicensing of both Monticello and Prairie Island as Xcel's carbon targets become increasingly stringent; the levelized cost of carbon abatement and 2045 rate impacts in the dual relicensing case are among the lowest of all the scenarios examined in this study.

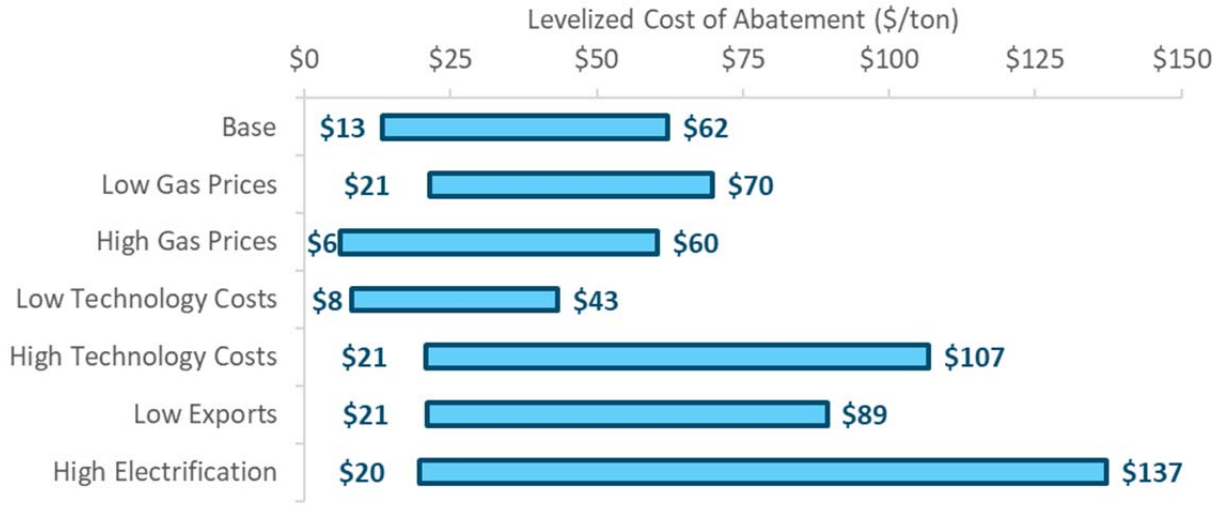
6 Conclusions

First—and perhaps most significantly—this study suggests that Xcel Energy can achieve substantial reductions in carbon emissions from its Upper Midwest portfolio at relatively low cost. Across the 21 scenarios examined in this study that achieve deep carbon reductions during the study horizon, the lowest-cost scenarios reduce carbon at a levelized cost of $15-20 per ton. The ability to achieve such large emissions reductions at such a relatively low cost results from several converging factors: (1) low natural gas prices, which enable low-cost fuel switching from coal to gas; (2) the relatively low (and falling) costs of new wind and solar resources due to technology improvements over the past decade; (3) a potential to increase deployment of energy efficiency and other demand-side programs to manage load growth; and (4) anticipated reductions in future battery storage costs, which enable integration of high penetrations of renewable generation.

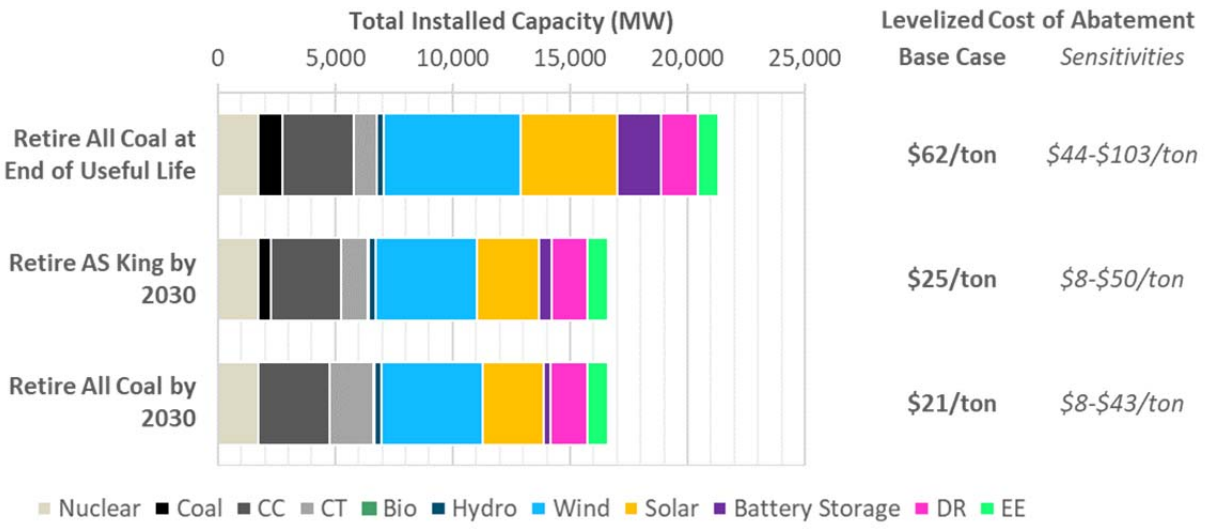
Figure 6-1. Range of carbon abatement costs across all scenarios and sensitivities.



The lowest-cost near-term opportunity to reduce carbon in Xcel's Upper Midwest system is to replace coal generation with a combination of renewables, storage, efficiency, and natural gas generation. The four coal plants owned by Xcel produce approximately 85% of the Upper Midwest system's greenhouse gas emissions in the 2020 Reference Case; while Xcel has already established plans to retire two of these plants prior to 2030, this analysis suggests that accelerating the retirement of its remaining two plants and replacing them with a portfolio of efficiency, renewables, storage, and natural gas generation provides the least-cost pathway to reducing emissions consistent with Xcel's 2030 goals (see Figure 6-2).

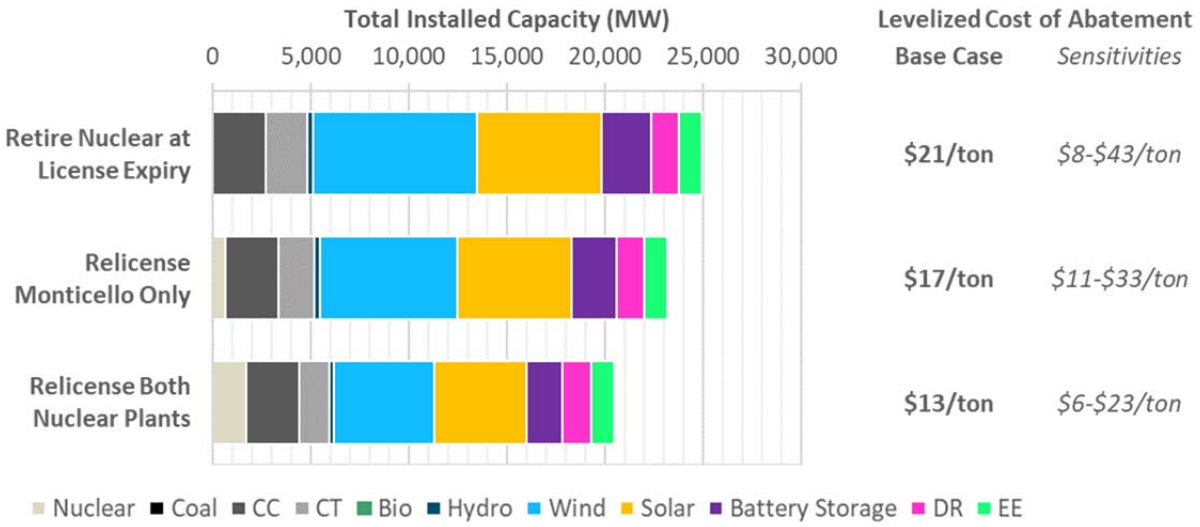
© 2019 Energy and Environmental Economics, Inc.

Figure 6-2. Snapshot of portfolios achieving 85% carbon reductions in 2030



A diverse portfolio of resources—including nuclear—offers the least-cost long-term pathway to deep carbon reductions. Beyond 2030, meeting Xcel's long-term carbon goals will require continued development of new carbon-free energy resources. At the same time, the expiration of existing licenses at both of Xcel's nuclear facilities in the early 2030s raises questions about the role of nuclear in Xcel's long-term generation portfolio. The scenario analysis conducted in this study suggests that under most circumstances, extending the licenses of both Monticello and Prairie Island to allow continued operation provides a least-cost option to meeting long-term carbon goals (Figure 6-3). This is due not only to the plants' ability to generate carbon-free electricity at relatively low cost but also, and perhaps more significantly, to the fact that nuclear generation (unlike wind, solar, or energy storage), as a "firm" resource, can generate at its full nameplate capacity for sustained periods when needed to meet Xcel's reliability needs. This unique combination of characteristics makes Xcel's existing nuclear plants inherently valuable to meeting Xcel's long-term carbon goals.

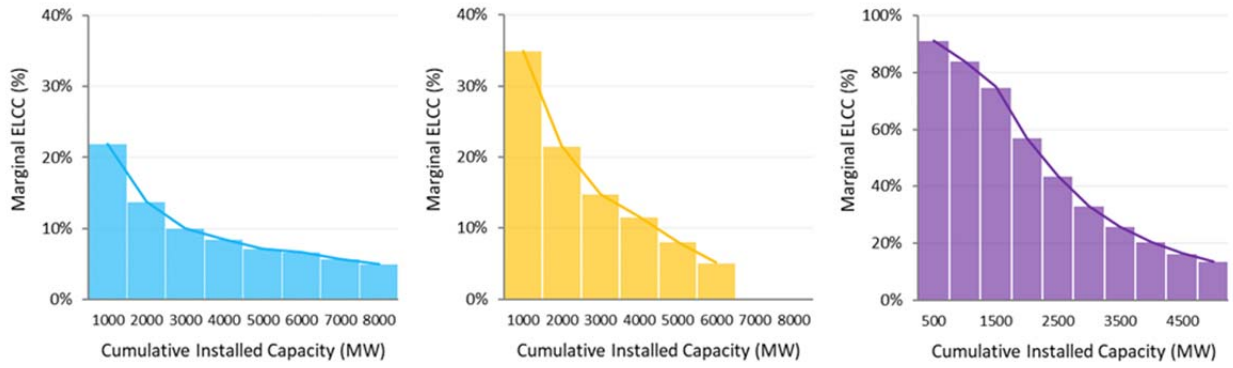
Figure 6-3. Xcel resource portfolios that achieve 95% carbon reductions in 2045



While new resources like wind, solar, and storage will play a central role in supplying carbon-free energy to Xcel's customers, these resources alone cannot meet Xcel's resource adequacy needs at reasonable costs. The reliability analysis conducted in this study highlights the limitations of renewable and storage resources to meet resource adequacy needs: due to variability and limits on duration, these resources offer less capacity value than firm resources that can produce at full capacity when needed. Further, because their marginal capacity value declines with increasing penetration, wind, solar, and storage offer a relatively poor substitute for traditional firm capacity resources in meeting reliability needs at scale (see Figure 6-4). Taken to an extreme, this study shows that a system designed to rely solely on renewables and storage to meet reliability needs would require prohibitively large investments. These findings underscore the need for an evolving approach to resource adequacy—by both Xcel and MISO—as renewables and storage reach greater levels of penetration. Such an approach is critical to ensure that sufficient resources are available even when variable renewables and storage alone cannot produce sufficient levels of generation to meet load.

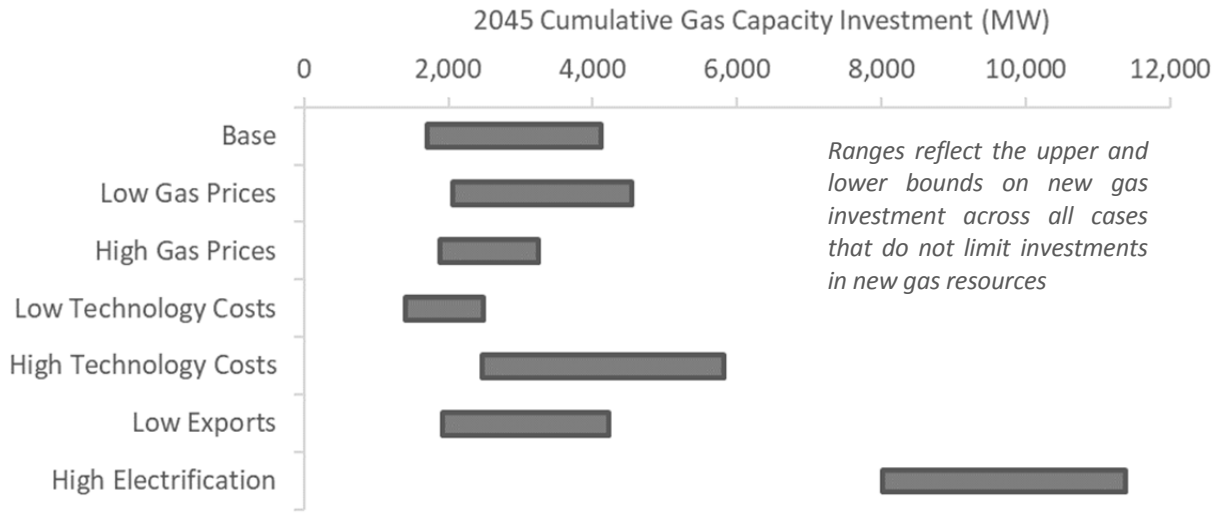
© 2019 Energy and Environmental Economics, Inc.

Figure 6-4. Marginal capacity values of wind, solar, and storage resources in Xcel's 2030 portfolio



Natural gas plants will be critically important to ensure a reliable system but will operate at low capacity factors. Because of the inherent limitations of renewables and storage resources to satisfy resource adequacy needs alone, some form of firm, dispatchable capacity will be needed to complement large anticipated investments in efficiency, renewables, and storage that needed to decarbonize Xcel's energy supply. While Xcel's existing nuclear plants are highly valuable because of their firm attributes, they alone are not sufficient to satisfy the need for firm capacity; natural gas resources will continue to play a crucial role in meeting system reliability. Figure 6-5 shows the range of new investments in natural gas resources across all the cases and sensitivities that allowed gas investment as part of the least-cost plan. Under Base Case assumptions, the level of new gas investments needed by 2045 spans a range from 2,000 to 4,000 MW (depending on whether existing nuclear plants are relicensed); among most other sensitivities, a similar range is observed. One sensitivity stands out for its outsized effect: in the High Electrification sensitivity, due to large new loads that increase winter peak significantly, the level of investment in new gas resources in least-cost portfolios is dramatically higher—8,000 to 11,000 MW. Collectively, these observations point to a more general finding: investment in new natural gas resources to meet capacity needs enables a low-cost pathway to decarbonize electricity and to facilitate levels of electrification needed to meet economy-wide carbon reduction goals.

Figure 6-5. Range of investments in new natural gas capacity resources by 2045 as part of a least-cost plan to achieve deep carbon reductions



Finally, while this study identifies a number of promising pathways towards Xcel's long-term carbon goals, the cost of achieving carbon reductions remains highly uncertain and subject to impacts of factors beyond the company's control. Even in the scenario that this study identifies as a least-cost plan—one that combined nuclear relicensing, accelerated coal retirements, and investments in renewables, storage, efficiency, and gas to meet long-term goals—the potential impacts upon retail rates calculated at the study's endpoint in 2045 spans a broad range from 150% above to 125% below the rate impact under Base Case assumptions. The largest potential sources of risk identified in this study result from uncertainty on the future cost of new renewable and storage resources and the uncertainty of how the changing generation mix in the broader MISO system will impact Xcel's opportunities to manage costs through market transactions. The exposure of Xcel's portfolio to such uncertainty and the associated risks underscores the importance of constant vigilance and responsiveness to rapidly changing market conditions as Xcel transitions towards a low carbon system.

Appendix A. RECAP Methodology

A.1 Background

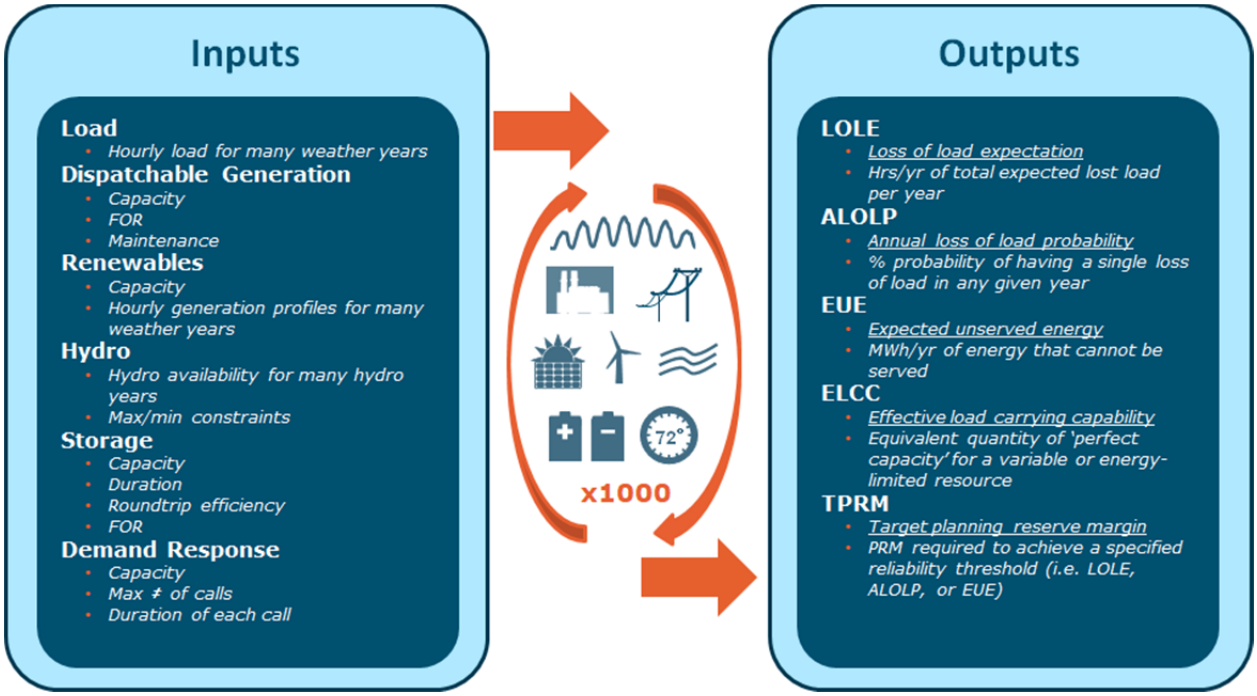
E3's **Renewable Energy Capacity Planning Model (RECAP)** is a loss-of-load-probability model designed to evaluate the resource adequacy of electric power systems, including systems with high penetrations of renewable energy and other dispatch-limited resources such as hydropower, energy storage, and demand response. RECAP was initially developed for the California Independent System Operator (CAISO) in 2011 to facilitate studies of renewable integration and has since been adapted for use in many jurisdictions across North America.

RECAP evaluates resource adequacy through time-sequential simulations of thousands of years of plausible system conditions to calculate a statistically significant measure of system reliability metrics as well as individual resource contributions to system reliability. The modeling framework is built around capturing correlations among weather, load, and renewable generation. RECAP also introduces stochastic forced outages of thermal plants and transmission assets and time-sequentially tracks hydro, demand response, and storage state of charge.

Figure A-1 provides a high-level overview of RECAP including key inputs, Monte Carlo simulation process, and key outputs.

© 2019 Energy and Environmental Economics, Inc.

Figure A-1. RECAP model overview



A.2 Model Inputs

RECAP is designed to allow loss of load probability simulation on a wide range of electricity systems that may comprise a diverse mix of generating resources, each with different constraints and characteristics that affect their availability to serve load at different times. The input data for RECAP, summarized in Table A-1, enables a robust evaluation of loss-of-load-probability that can account for a broad variety of technologies and resource types, including:

- **Firm resources** capable of producing at their full rated capacity when called upon by operators (except during periods of maintenance and unforced outages);
- **Variable resources**, typically wind and solar, whose availability will vary on an hourly basis as a result of weather and solar irradiance patterns;

- **Hydroelectric resources** that can be dispatched relatively flexibly but have constraints related to streamflow and underlying hydrological conditions;
- **Storage resources** that can be dispatched flexibly but have limited durations across which they are available due to limits on state of charge; and
- **Demand response programs** that can be called upon as a last resort by operators to maintain reliability but typically have limits on the frequency and duration of calls that vary depending on the type of program.

Table A-1. Key inputs to RECAP model

Module	Inputs Needed
Load	• Annual energy demand • Annual 1-in-2 peak demand • Hourly profiles corresponding to a wide range of weather conditions (20+ years)
Firm Resources *(e.g. nuclear, coal, gas, biomass, geothermal)*	• Installed capacity by resource • Forced outage rate by resource • Maintenance profiles by resource
Variable Resources *(e.g. wind, solar, run-of-river hydro)*	• Installed capacity by resource • Hourly profiles for multiple years, ideally including multiple years of overlap with hourly load profile data
Imports/Market Purchases	• Assumed level of imports available from external markets available to contribute to portfolio reliability needs
Hydroelectric Resources	• Installed capacity by resource • Monthly/daily energy budgets across a range of plausible hydro conditions • Minimum output levels by month/day • Sustained peaking limitations by month/day
Storage Resources *(e.g. batteries, pumped storage)*	• Installed capacity by resource • Storage reservoir size by resource • Round-trip efficiency by resource
Demand Response Resources	• Program size by program • Limits on program calls (e.g. number of calls per year/month/day, length of calls)

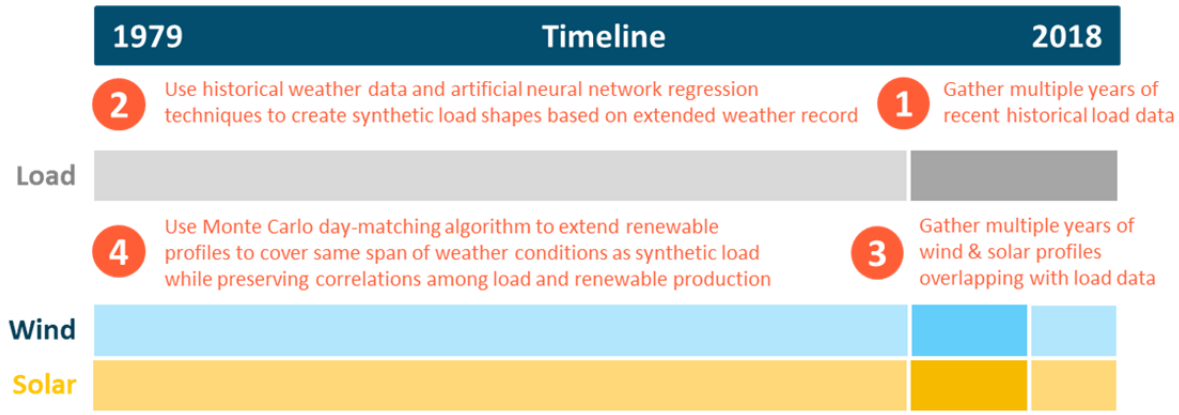
A.3 Model Methodology

A.3.1 LOAD & RENEWABLE SIMULATION

Generating an extensive record of load and renewable profiles that capture both the range of variability of each as well as the key correlations between them is a necessary but challenging step in reliability modeling. To generate such a record, RECAP relies upon historical time-synchronous load and renewable profiles but also uses statistical approaches to extend what is typically a limited historical record. The four-step process used in RECAP is shown in Figure A-2.

Figure A-2. Illustration of processes used to generate load & renewable profiles for RECAP



Step 1: Gather historical load data for multiple recent years

The hourly and seasonal patterns of load are typically captured in RECAP through the actual observed patterns of hourly load metered by utilities, RTOs, or others. In general, multiple years of recent historical load data (5-10 years) is collected to provide a reasonable breadth of potential underlying weather conditions.

Step 2: Use neural network regression to simulate hourly loads across long-run weather record

Typically, the availability of historical hourly load data that can be practically incorporated into RECAP is limited—both by data availability and by the fact that historic load shapes from previous years may not appropriately reflect the composition of end uses and customers that make up today's system (an issue that becomes increasingly pronounced farther back in time). At the same time, a rigorous approach to measuring reliability requires consideration of a breadth of potential weather conditions.

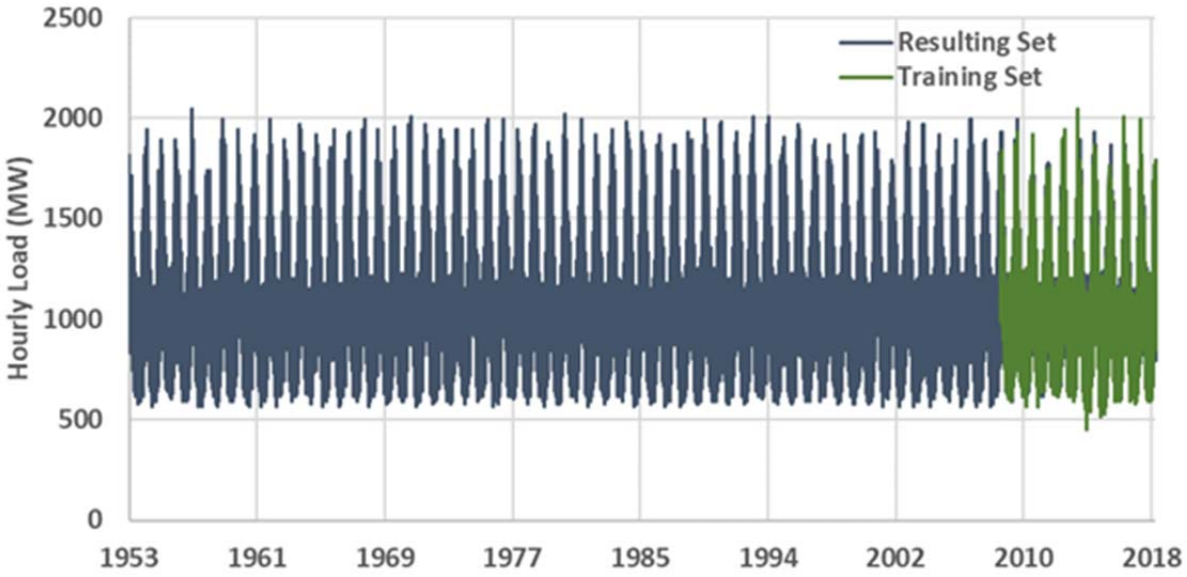
To allow consideration of a broad range of potential weather conditions observed across multiple decades in spite of the lack of useful historical load data during most of that period, RECAP uses a neural network regression algorithm to extend a relatively shorter sample of actual historical load data across a longer period based on key weather indicators and drivers across that longer period. The neural network algorithm is trained with a set of historical loads and associated underlying weather data and then used to simulate load levels that reflect the composition of end uses and the underlying economic conditions that reflect today's electricity demands while also capturing the underlying weather conditions across a much broader record. The key variables included in the neural network regression include:

- Daily minimum and maximum temperatures at multiple weather stations;
- An indicator for month (+/- 15 days);
- A flag for day-type (weekend vs. weekday);
- A day index to account for any growth observed during the training period.

Figure A-3 shows an example of the results of this process. The resulting shape can be scaled upward or downward to the appropriate level of annual and peak demand to match a future system's expected demand growth.

© 2019 Energy and Environmental Economics, Inc.

Figure A-3. Example of results of neural network regression to extend load across long weather record



Step 3: Gather historical (or simulated) renewable profiles for multiple recent years

Multiple years of actual and/or simulated hourly profiles for wind and solar resources are a key input to RECAP. Whenever possible, actual historical metered data is preferred, but in its absence (given the relatively small amount of renewable generation existing today), simulated hourly profiles from sources like NREL's WIND Toolkit and NREL's System Advisor Model provide coverage across multiple historical years (2007-'12 and 1998-'18, respectively). Several considerations are important in developing this data set:

- Hourly profiles should capture multiple years. The potential variability of renewable generation, particularly during periods of extreme load, is high enough that a single year may not appropriately capture its expected production during those periods. Therefore, multiple years (typically at least four) are needed.

- Hourly profiles should correspond to a period for which load data is also available. Developing a dataset of load and renewables that is weather-matched based on actual historical conditions allows the modeling to account for the actual observed correlations between load and renewables.
- Hourly profiles for wind and solar should (ideally) cover the same historical period. Like above, this allows the model to preserve actual observed correlations between wind and solar—not just between load and each renewable technology independently.

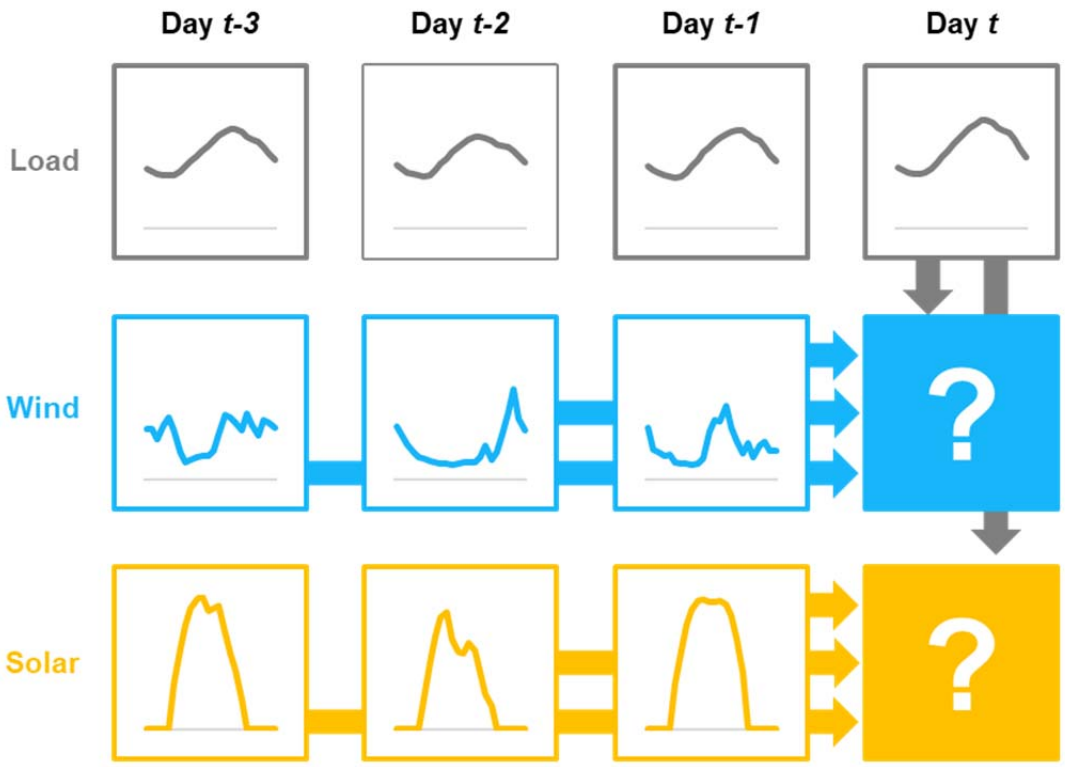
Step 4: Use a probabilistic day-matching algorithm to match renewable profiles to extended weather record

A stochastic rolling day-matching algorithm is used to match the limited sample of renewable profiles with the extended record of simulated load data using the observed relationship for years with overlapping data i.e., years with available renewable data. The day matching algorithm, illustrated in Figure A-4, selects a renewable profile for each day of the simulation based the corresponding level of load in that day and the level of renewable generation in the prior day(s).[8] The potential sample of renewable profiles from the historical record that are considered as potential matches for each day in the extended record is also restricted to days within +/- 15 calendar days of that day to ensure that seasonal factors (e.g. variations in patterns of insolation, which affects solar production on a seasonal basis) are also accounted for in the process. Ideally, this day matching algorithm can be run on both wind and solar profiles simultaneously—this is possible when the historical records for wind and solar profiles are contiguous—but the algorithm can also be run independently on wind and solar if overlapping records are not available.

[8] The number of prior days' renewable generation included in the matching algorithm can be varied as needed to ensure that extended weather events observed in the historical record (e.g. multi-day storm systems) occur within the stochastic simulation.

© 2019 Energy and Environmental Economics, Inc.

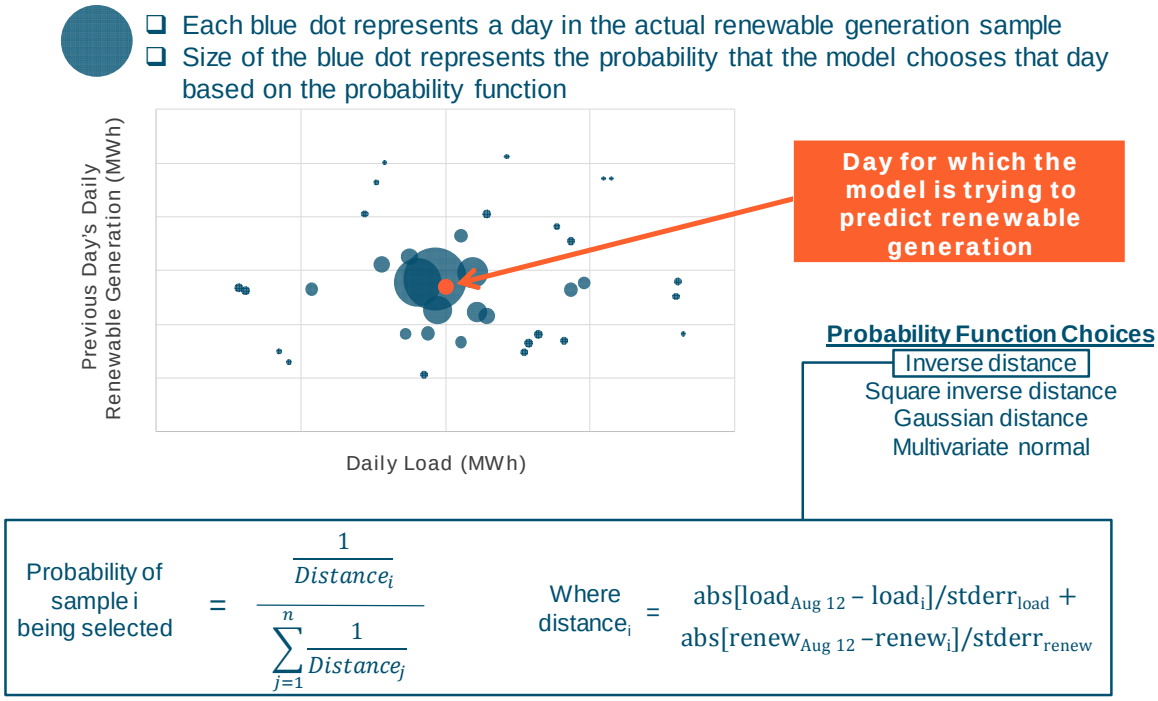
Figure A-4. Illustration of day-matching algorithm used to extend record of renewable profiles to match loads



The algorithm used to select renewable profiles is a probabilistic one that allows for stochastic pairings of load and renewable shapes—in other words, multiple plausible combinations of load and corresponding renewable profiles are generated for the extended weather record. The probability that any specific day from the historical weather record will be selected as a match is based on an inverse distance algorithm that measures the similarity between each possible day of renewable profiles in the historical record and the desired day in the longer record and assigns a probability to each one. Figure A-5 illustrates the assignment of probabilities for a specific individual day; the days in the historical

record that are "closest" to that day (in terms of that day's load and the previous day's renewable generation) are assigned the highest probability.

Figure A-5. Renewable profile selection process



A.3.2 LOSS OF LOAD PROBABILITY SIMULATION

Based on the inputs described above, RECAP simulates the loss of load probability for an electric system using a Monte Carlo approach to capture plausible combinations of load, variable renewables, and outages across hundreds of potential years. For each broad class of resource enumerated above, RECAP includes a module that evaluates the ability of each resource in that class to contribute to load in each hour of the simulation. The methodology used in each module is presented in

© 2019 Energy and Environmental Economics, Inc.

Table A-2. Overview of methodology used to compare load and resource availability

Module	Methodology
Load	The hourly profile of electricity demand is determined based on an hourly load shape that covers a broad range of historical weather conditions (multiple decades) that is scaled to the desired level of annual and peak demand. The underlying load shape itself is a result of a pre-processing neural network regression that simulates hourly load shapes for the full available weather record based on recent historical loads and a longer record of weather data.
Firm Resources *(e.g. nuclear, coal, gas, biomass, geothermal)*	Available dispatchable generation is calculated stochastically in RECAP using forced outage rates (FOR) and mean time to repair (MTTR) for each individual generator. These outages are either partial or full plant outages based on a distribution of possible outage states. Over many simulated days, the model will generate outages such that the average generating availability of the plant will yield a value of (1-FOR).
Variable Resources *(e.g. wind, solar, run-of-river hydro)*	Availability of variable renewable resources is simulated stochastically based on the rolling probabilistic day-matching algorithm described above. This results in an hourly timeseries profile for all variable resources that aligns with the hourly load profile.
Imports/Market Purchases	Availability of generic resources from external areas (i.e. assumed wholesale market purchases) can be specified at an hourly, monthly, or annual level. This is an input to RECAP.
Hydroelectric Resources	To determine hydro availability, the model uses a monthly historical record of hydro production. For every simulated load year, a hydro year is chosen stochastically from the historical database. Associated hydro budgets are typically assigned on either a weekly or daily basis and then "dispatched" to minimize net load (load less variable resources and hydro) during that period while accounting for a number of constraints, including: • Minimum output levels that capture the lower limit on the level of generation that a system may produce when considering hydrological and other physical constraints on the system • Sustained peaking limits, which limit the output of the hydro system across a range of rolling time windows (e.g. 1-hour, 2-hour, 4-hour, and 10-hour) to capture how hydrological factors may limit the ability to discharge water through a dam for sustained periods of time.
Storage Resources *(e.g. batteries, pumped storage)*	The model dispatches storage if there is insufficient generating capacity to meet load net of renewables and hydro. Storage is reserved specifically for reliability events where load exceeds available generation. It is important to note that storage is not dispatched for economics in RECAP which in many cases is how storage would be dispatched in the real world. However, it is reasonable to assume that the types of reliability events that storage is being dispatched for (low wind and solar events), are reasonably foreseeable such that the system operator would ensure that storage is charged to the extent possible in advance of these events. (Further, presumably prices would be high during these types of reliability events so that the dispatch of storage for economics also would satisfy reliability objectives).

Module	Methodology
Demand Response Resources	The model dispatches demand response if there is still insufficient generating capacity to meet load even after storage. Demand response is the resource of last resort since demand response programs often have a limitation on the number of times they can be called upon over a set period of time. For this study, demand response was modeled using a maximum of 10 calls per year, with each call lasting for a maximum of 4 hours.

To the extent the portfolio of resources whose availability is determined through the steps above is insufficient to meet demand in any hour, a loss of load event is recorded. After simulating hundreds of years of possible Monte Carlo outcomes, RECAP calculates the system's LOLE and a variety of other reliability statistics.

A.3.3 EFFECTIVE LOAD CARRYING CAPABILITY CALCULATION

The simulation of LOLE for a given electric system enables the calculation of "effective load carrying capability" (ELCC) for individual resources, or, in more colloquial terms, their capacity value: a measure of the equivalent amount of "perfect capacity" that could be replaced with the addition of a specified resource while maintaining the same level of reliability. ELCC for individual resources (or combinations of resources) is calculated through iterative simulations of an electric system:

1. The LOLE for the electric system without the specified resource is simulated. If the resulting LOLE does not match the specified reliability target, the system "adjusted" to meet a target reliability standard (most commonly, one day in ten years). This adjustment occurs through the addition (or removal) of perfect capacity resources to achieve the desired reliability standard.
2. The specified resource is added to the system and LOLE is recalculated. This will result in a reduction in the system's LOLE, as the amount of available generation has increased.
3. Perfect capacity resources are removed from the system until the LOLE returns to the specified reliability target. The amount of perfect capacity removed from the system represents the ELCC of the specified resource (measured in MW); this metric can also be translated to percentage terms by dividing by the installed capacity of the specified resource.

© 2019 Energy and Environmental Economics, Inc.

This approach can be used to determine the ELCC of any specific resource type evaluated within the model. In general, ELCC is not widely used to measure capacity value for firm resources (which are generally rated either at their full or unforced capacity) but provides a useful metric for characterizing the capacity value of renewable, storage, and demand response resources.

The ELCC of a resource depends not only on the characteristics of load in a specific area (i.e. how coincident its production is with load) but also upon the resource mix of the existing system (i.e. how it interacts with other resources). For instance, ELCCs for variable renewable resources are generally found to be higher on systems with large amounts of inherent storage capability (e.g. large hydro systems) than on systems that rely predominantly on thermal resources and have limited storage capability. ELCCs for a specific type of resource are also a function of the penetration of that resource type; in general, most resources exhibit declining capacity value with increasing scale. This is generally a result of the fact that continued addition of a single resource or technology will lead to saturation when that resource is available and will shift reliability events towards periods when that resource is not available. The diminishing impact of increasing solar generation as the net peak shifts to the evening illustrates this effect.

A.3.4 PLANNING RESERVE MARGIN CALCULATION

The results of RECAP can also be translated into a simpler and more widely used planning reserve margin requirement (PRM), a target for system reliability expressed as a percentage requirement above expected peak demand. PRM requirements are used by many utilities and RTOs in their administration of resource adequacy requirements. Thus, RECAP also expresses its outputs in terms of the PRM:

- The “actual” PRM of a system is calculated based on the summation of capacity provided by all resources; firm resources are rated at nameplate capacity, while hydro, variable, and use-limited resources are rated based on ELCC endogenously calculated as described above. This total amount of capacity is divided by the expected peak to provide a planning reserve margin.

- The "target" PRM of a system (i.e. the PRM needed to achieve a corresponding specified LOLE target) is calculated by adjusting the starting system as needed with perfect capacity resources to achieve the desired LOLE. The PRM for this adjusted system then represents the reserve margin needed to meet the comparable LOLE standard.

A.4 Key Model Outputs

A primary benefit of the RECAP model is the ability to produce an array of summary results that give insight into system reliability and the nature of frequency, magnitude, and duration of loss of load events on an electric system. The summary reliability statistics produced include:

- **Loss of load expectation (LOLE, measured in days per year),** the expected number of days in which loss-of-load events occur in each year;
- **Loss of load hours (LOLH, measured in hours per year),** the expected number of hours of lost load in each year;
- **Loss of load events (LOLEV, measured in events per year),** the expected number of reliability events that occur within each year;
- **Annual loss of load probability (ALOLP, measured in %),** the probability that at least one loss-of-load event will occur within a year; and
- **Expected unserved energy (EUE, measured in MWh per year),** the expected amount of unserved load within each year.

RECAP also produces a number of metrics that help translate these detailed reliability statistics into a more typical planning reserve margin framework. If the user specifies a specific reliability target (for example 0.1 days/yr LOLE, or "one day in ten years"), the model calculates the required quantity of capacity necessary to achieve that level of reliability through an internal search algorithm. Comparing the required quantity of capacity to the median (1-in-2) peak load yields the target planning reserve margin while comparing it to the quantity of existing firm capacity on the system yields a net capacity shortage. Included in this measure

© 2019 Energy and Environmental Economics, Inc.

of firm capacity is the effective load carrying capability (ELCC) of all non-firm resources including wind, solar, hydro, demand response, and battery storage.

Appendix B. RESOLVE Methodology

B.1 Overview

RESOLVE is a resource investment model that uses linear programming to identify optimal long-term generation and transmission investments in an electric system, subject to reliability, technical, and policy constraints. Designed specifically to address the capacity expansion questions for systems seeking to integrate large quantities of variable resources, RESOLVE layers capacity expansion logic on top of a production cost model to determine the least-cost investment plan, accounting for both the up-front capital costs of new resources and the variable costs to operate the grid reliably over time. In an environment in which most new investments in the electric system have fixed costs significantly larger than their variable operating costs, this type of model provides a strong foundation to identify potential investment benefits associated with alternative scenarios.

RESOLVE's optimization capabilities allow it to select from among a wide range of potential new resources. In general, the options for new investments considered in this study are limited to those technologies that are commercially available today. This approach ensures that the greenhouse gas reduction portfolios developed in this study can be achieved without relying on assumed future technological breakthroughs. At the same time, it means that emerging technologies that could play a role in a low-carbon future for the Midwest—for instance, small modular nuclear reactors—are not evaluated within this study. This modeling choice is not meant to suggest that such emerging technologies should not have a role in meeting regional greenhouse gas reduction goals, but instead reflects a simplifying assumption made in this study. The full range of resource options considered by RESOLVE in this study is shown in Table B-1.

© 2019 Energy and Environmental Economics, Inc.

Table B-1. Resource options considered in RESOLVE

Resource Option	Examples of Available Options	Functionality
Natural Gas Generation	• Simple cycle gas turbines • Reciprocating engines • Combined cycle gas turbines	• Dispatches economically based on heat rate, subject to ramping limitations • Contributes to meeting minimum generation and ramping constraints
Renewable Generation	• Solar PV • Wind • Biogas	• Dynamic downward dispatch (with cost penalty) of renewable resources to help balance load
Energy Storage	• Batteries (>1 hr)	• Stores excess energy for later dispatch • Contributes to meeting minimum generation and ramping constraints
Energy Efficiency	• HVAC • Lighting • Dryer, refrigeration, etc.	• Reduces load, retail sales, planning reserve margin need
Demand Response	• Saver's Switch • Interruptible tariff • Critical Peak Pricing	• Contributes to planning reserve margin needs

B.2 Operational Simulation

To identify optimal investments in the electric sector, maintaining a robust representation of prospective resources' impact on system operations is fundamental to ensuring that the value each resource provides to the system is captured accurately. At the same time, the addition of investment decisions across multiple periods to a traditional unit commitment problem increases its computational complexity significantly. RESOLVE's simulation of operations has therefore been carefully designed to simplify traditional unit commitment problem where possible while maintaining a level of detail

sufficient to provide a reasonable valuation of potential new resources. The key attributes of RESOLVE's operational simulation are enumerated below:

- **Hourly chronological simulation:** RESOLVE's representation of system operations uses an hourly resolution to capture the intraday variability of load and renewable generation. This level of resolution is necessary in a planning-level study to capture the intermittency of potential new wind and solar resources, which are not available at all times of day to meet demand and must be supplemented with other resources.
- **Aggregated generation classes:** rather than modeling each generator within the study footprint independently, generators in each region are grouped together into categories with other plants whose operational characteristics are similar (e.g. nuclear, coal, gas CCGT, gas CT). Grouping like plants together for the purpose of simulation reduces the computational complexity of the problem without significantly impacting the underlying economics of power system operations.
- **Linearized unit commitment:** RESOLVE includes a linear version of a traditional production simulation model. In RESOLVE's implementation, this means that the commitment variable for each class of generators is a continuous variable rather than an integer variable. Additional constraints on operations (e.g. Pmin, Pmax, ramp rate limits, minimum up and down time) further limit the flexibility of each class' operations.
- **Zonal transmission topology:** RESOLVE uses a zonal transmission topology to simulate flows among the regions represented in the analysis as model zones. In this study RESOLVE includes four zones: Xcel's Upper Midwest territory, NSP – the Primary Zone; MISO Load Resource Zone (LRZ) 1, MISO LRZ2, and MISO LRZ3. Given Xcel's territory exists primarily in MISO LRZ1, the NSP zone can only interact with LRZ1; while LRZ1 has ties to both LRZ2 and LRZ3.
- **Co-optimization of energy and ancillary services:** RESOLVE dispatches generation to meet load across the modeled regions, while simultaneous reserving flexible capacity within the Primary Zone to meet the contingency and flexibility reserve needs. As systems become increasingly constrained on flexibility, the inclusion of ancillary service needs in the dispatch problem is necessary to ensure a reasonable dispatch of resources that can serve load reliably.

© 2019 Energy and Environmental Economics, Inc.

- **Smart sampling of days:** whereas production cost models are commonly used to simulate an entire calendar year (or multiple years) of operations, RESOLVE simulates the operations of the modeled system for a number of sampled independent days. Load, wind, and solar profiles for these selected days, sampled from the historical meteorological record over a specified period, are selected and assigned weights so that taken in aggregate, they produce a reasonable representation of complete distributions of potential conditions.[9] This allows RESOLVE to approximate annual operating costs and dynamics while simulating operations for only the selected days. In this study, a sample of 37 days is used, based on historical meteorological record from 2009 to 2012.
- **Hydro dispatch informed by historical operations:** RESOLVE captures the inherent limitations of the generation capability of the hydroelectric system by deriving constraints from actual operational data. Three types of constraints govern the operation of the hydro fleet as a whole: (1) daily energy budgets, which limit the amount of hydro generation in a day;[10] (2) maximum and minimum hydro generation levels, which constrain the hourly hydro generation; and (3) maximum multi-hour ramp rates, which limit the rate at which the output of the collective hydro system can change its output across periods from one to four hours. Collectively, these constraints limit the generation of the hydro fleet to reflect seasonal limits on water availability, downstream flow requirements, and non-power factors that impact the operations of the hydro system. The derivation of these constraints from actual hourly operations makes this representation of hydro operations conservative with respect to the amount of potential flexibility in the resource.

[9] An optimization algorithm is used to select the days and identify the weight for each day such that distributions of load, net load, wind, and solar generation match long-run distributions. For further detail on the smart sampling algorithm used in RESOLVE, see **Error! Reference source not found.**.

[10] Sometimes hydro operators can shift hydro energy from day to day: for example, if hydro operators know that tomorrow will be a peak day, they can save some hydro energy today and use them tomorrow to meet the system need. This flexibility can help integrating renewable into the system and it is going to be more and more valuable as the % of system renewable penetration increases. To capture this flexibility, model allows up to 5% of the hydro energy in each day to be shifted around within two months.

B.3 Additional Constraints

RESOLVE layers investment decisions on top of the operational model described above. Each new investment identified in RESOLVE has an impact on how the system operates; the portfolio of investments, as a whole, must satisfy a number of additional conditions.

- **Planning reserve margin:** When making investment decisions, RESOLVE requires the portfolio to include enough firm capacity to meet 1-in-2 system peak plus an additional specified amount of planning reserve margin (PRM) requirement. The contribution of each resource type towards this requirement depends on its attributes and varies by type: for instance, variable renewables are discounted more compared to thermal generations because the uncertainties of generation during peak hours. In this study, a PRM requirement of 3% is used for the Xcel Upper Midwest system.
- **Renewables Portfolio Standard (RPS) requirement:** RPS requirements have become the most common policy mechanism in the United States to encourage renewable development. RESOLVE enforces an RPS requirement as a percentage of retail sales to ensure that the total quantity of energy procured from renewable resources meets the RPS target in each year.
- **Greenhouse gas cap:** RESOLVE also allows users to specify and enforce a greenhouse gas constraint on the resource portfolio for a region. As the name suggests, the emission cap type policy requires that annual emission generated in the entire system to be less than or equal to the designed maximum emission cap. This type of policy is usually implemented by having limited amount of emission allowances within the system. As a result, thermal generators need to purchase allowances for the carbon they produced from the market or from carbon-free generators.
- **Resource potential limitations:** Many potential new resources are limited in their potential for new development. This is particularly true for renewable resources such as wind and solar. RESOLVE enforces limits on the maximum potential of each new resource that can be included in the portfolio, imposing practical limitations on the amount of any one type of resource that may be developed.

© 2019 Energy and Environmental Economics, Inc.

RESOLVE considers each of these constraints simultaneously, selecting the combination of new generation resources that adheres to these constraints while minimizing the sum of investment and operational costs.

B.4 Key Model Outputs

RESOLVE produces a large amount of results from technology level unit commitment decisions to total carbon emission in the system. This extensive information gives users a complete view of the future system and makes RESOLVE versatile for different analysis. The following list of outputs is produced by RESOLVE and are the subject of discussion and interpretation in this study:

- **Total revenue requirement ($/yr):** The total revenue requirement reports the total costs incurred by utilities in the study footprint to provide service to its customers. This study focuses on the relative differences in revenue requirement among scenarios, generally measuring changes in the revenue requirement relative to the Reference Case. The cost impacts for each scenario comprise changes in fixed costs (capital & fixed O&M costs for new generation resources, incremental energy efficiency, new energy storage devices, and the required transmission resources with the new generation) and operating costs (variable O&M costs, fuel costs, costs of market purchases and revenues from surplus sales).
- **Greenhouse gas emissions (MMTCO2e):** This result summarizes the total annual carbon emission in the system with imports and exports adjustments. By comparing the carbon emissions and total resource costs between different scenarios, we can conclude the relative effectiveness of the strategic measure in enabling carbon reductions.
- **Resource additions for each period (MW):** The selected investment summarizes the cumulative new generation capacity investments by resources type. It provides an overview of what is built to meet both operational and emissions constraints over time.
- **Annual generation by resource type (GWh):** Energy balance shows the annual system load and energy produced by each resource type in each modeled year. It provides insights from a different angle than capacity investments. It can help answer questions like: Which types of

resources are dispatched more? How do the dispatch behaviors change over the years? And how do curtailment, imports, and exports vary year by year?

+ **Renewable curtailment (GWh):** RESOLVE estimates the amount of renewable curtailment that would be expected in each year of the analysis as a result of "oversupply"—when the total amount of must-run and renewable generation exceeds regional load plus export capability—based on its hourly simulation of operations. As the primary renewable integration challenge at high renewable penetrations, this measure is a useful proxy for renewable integration costs.
+ **Wholesale market prices ($/MWh):** outputs from RESOLVE can be used to estimate wholesale market prices on an hourly basis. As an optimization model, RESOLVE produces "shadow prices" in each hour that represent the marginal cost of generation given all the resources available at the time; these marginal costs serve as a proxy for wholesale market prices.
+ **Average greenhouse gas abatement cost ($/metric ton):** RESOLVE results can also be used to estimate average and marginal costs of greenhouse gas abatement by comparing the amount of greenhouse gas abatement achieved (relative to a Reference Case) and the incremental cost (relative to that same case).

For this study, most results focus on the snapshots of the system in 2030 and 2045, which correspond to key milestones for Xcel. However, in some cases, intermediate results are also presented when relevant to the study's objectives and key messages.

Appendix C. Additional Inputs & Assumptions

C.1 Load & Renewable Profiles

C.1.1 PROFILE DEVELOPMENT

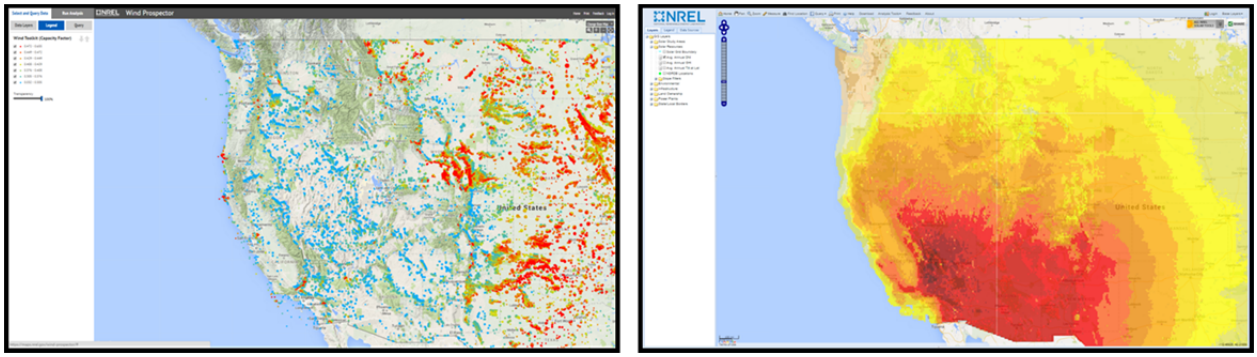
Xcel provided hourly load information from 2009 – 2012 for the Upper Midwest system. These loads were normalized to create a shape based on real data that could be applied to forecasted peak and demand for the study. While we acknowledge that these hourly profiles will change in the future, the statistical methods used in the RESOLVE day sampling methodology and RECAP neural network capture realistic relationships between load and renewable generation – all driven primarily by weather patterns – that should remain consistent in the future. For the portions of future load growth that represent inherently different characteristics than seen today – namely, electric space heating, electric water heating, and electric vehicles for the High Electrification sensitivity – the E3 PATHWAYS team worked with Xcel to generate separate load profiles that are layered on top of the base load discussed. PATHWAYS, which is a stock rollover model developed by E3 used to analyze economy-wide pathways to achieve deep decarbonization goals, was used to forecast the gross levels of electrification loads. These Minnesota-wide loads were scaled down proportionally for the Xcel Upper Midwest system, but the hourly profiles for each technology stayed consistent.

Hourly profiles for wind and solar generation are derived from the National Renewable Energy Laboratory's (NREL) WIND Toolkit and Solar Prospector, respectively (see Figure C-1), for the same set of load years. The WIND Toolkit provides simulated output for a large number of selected sites throughout the western United States derived using a mesoscale weather model. The Solar Prospector provides historical hourly irradiance data, which is used to simulate the output of hypothetical solar PV plants throughout the west. Various sites were chosen to create aggregate profiles that represent different

© 2019 Energy and Environmental Economics, Inc.

regions in the broad Xcel Upper Midwest service territory. These sites were screened and aggregated considering general location, MISO LRZ, and relatively close-by transmission interconnections. This resulted in four representative regions in Minnesota, two in Wisconsin, four in Iowa, and four in North Dakota. Each region was assigned a unique solar and wind profile. Both wind and solar profiles used in this study are scaled to match anticipated regional capacity factors.

Figure C-1. Screenshots from NREL's Wind Prospector (left) and Solar Prospector (right)



C.1.2 RECAP NEURAL NETWORK

As is often the case, the historical load record available to Xcel is far exceeded by historical weather data. RECAP relies on a neural network model to predict load given the relationship observed between real weathers and load data. Given a set of temporally matching historical temperature and load, the neural network develops a regression model by which it can then use to predict historical load given temperature data and other predictor data. In doing so, the available load data is effectively extended from a few years to fifty years or more.

E3 modeled hourly load in Xcel under consistent set of economic conditions using the weather years 1950-2012 using a neural network model. This process develops a relationship between recent daily load and the following independent variables:

- Max and min daily temperature (including one and two-day lag)
- Month (+/- 15 calendar days)
- Day-type (weekday/weekend/holiday)
- Day index for economic growth or other linear factor over the recent set of load data

The neural network model establishes a relationship between daily load and the independent variables by determining a set of coefficients to different nodes in hidden layers which represent intermediate steps in between the independent variables (temp, calendar, day index) and the dependent variable (load). The model trains itself through a set of iterations until the coefficients converge. Using the relationship established by the neural network, the model calculates daily load for all days in the weather record (1950-2012) under 2012 economic conditions. The final step converts these daily load totals into hourly loads. To do this, the model searches over the actual recent load data (4 years) to find the day that is closest in total daily load to the day that needs an hourly profile. The model is constrained to search within identical day-type (weekday/weekend/holiday) and +/- 15 calendar days when making the selection. The model then applies this hourly load profile to the daily load MWh.

This hourly load profile for the weather years 1950-2012 under 2012 economic conditions is then scaled to match the load forecast for future years in which RECAP is calculating reliability. This ”base” load profile only captures the loads that are present on the electricity system today and do not very well capture systematic changes to the load profile due to increased adoption of electric vehicles, building space and water heating, industrial electrification. Load modification through demand response is captured through explicit analysis of this resource.

Operating reserves of 200 MW are also added onto load in all hours with the assumption being that the system operator will shed load in order to maintain operating reserves of at least 200 MW in order to prevent the potentially more catastrophic consequences that might result due to an unexpected grid event coupled with insufficient operating reserves.

© 2019 Energy and Environmental Economics, Inc.

C.1.3 RESOLVE DAY SAMPLING

Computation can be challenging for a model like RESOLVE that makes both investment and operational decisions across a long period of time. To alleviate this challenge, instead of simulating the system operation for an entire year, a subset of days is modeled to approximate the annual operating costs. In order to approximate the annual system operating costs while simulating only a subset of the number of days in a year, RESOLVE relies on a pre-processing sampling algorithm to select a combination of days whose characteristics are, together, representative of the conditions experienced by an electricity system over the course of multiple years. This pre-processing step uses optimization to sample a subset of conditions that, when taken in aggregate and weighted appropriately, provide a reasonable representation of the breadth of load, wind, and solar conditions observed in the historical record.

A multi-objective optimization model is used to pick a set of days (and associated weights) to match historical conditions for key indicators while also minimizing the number of days selected. The process for selecting the set of representative days follows several steps:

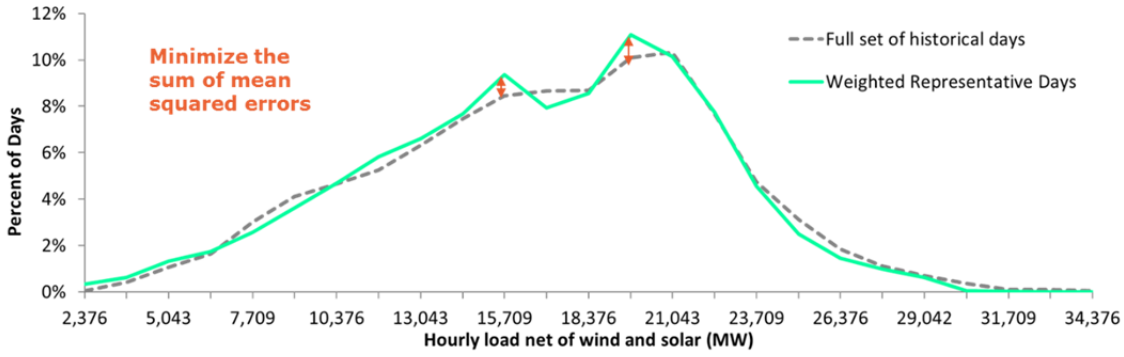
1. **Determine the number and type of days to select:** The user defines the number of days to be selected in the final subset, the minimum day weight to be assigned (so that each day selected has at least a certain importance associated), and optional day types for categorizing different selected days.
2. **The candidate pool of days is created:** Load, wind, and solar profiles are sampled from timeseries data as a representative sample of shapes. In the 2016 PSIP cases, we used simulated 2016 data for the representative sample; however, the algorithm can use multiple years of data to capture different weather years within its sample.
3. **Key variables are selected:** Key variables are selected as indicators for system conditions. In this study, the variables used to characterize the representation of a sample include: (1) distributions of hourly and daily load, net load, wind, and solar production; (2) distribution of hourly ramps of load net of wind and solar; (3) number of days per month; and (4) site-specific annual capacity factors for wind and solar profiles. These variables can also be weighted

differently, which allows the optimization model to prioritize the more important variables with higher weights when matching the distribution. This study prioritizes fit on the distributions for load, wind, and hydro conditions, as these three factors have a significant effect on the operations of the electric system.

4. **Optimization model selects an optimal set of days: From the candidate pool of days established in the first step, the optimization selects a set of days while minimizing the absolute errors for each of the criteria. If optional day types have been assigned by the user, t**he day selection algorithm will attempt to select at least one of each day type in the final sample. **The output from the optimization algorithm includes a set of days, as well as associated weights through which those days may be weighted to represent a** historic average year.

An optimization model is used in the day sampling process. As shown in Figure C-2 below, one component of the minimization is the alignment between historical and sampled hourly load distributions: the distribution of historical hourly net load is plotted as dotted gray line in the chart, and the model selects and weights a subset of days to match the historical distributions.

Figure C-2. Example of net load distribution



The mathematical formulation to minimize absolute error is show below:

© 2019 Energy and Environmental Economics, Inc.

min: $$\sum_{b \in Bins} \left| OverallFreq_b - \sum_{d \in Days} \left(weight_d \times DailyFreq_{d,b} \right) \right|$$

subject to:

$$\sum_{d \in Days} weight_d = 1$$

$$weight_d \geq LowerBound \quad \forall\, d \in Days$$

$$SelectedDayIndicator_d \geq weight_d \quad \forall\, d \in Days$$

$$\sum_{d \in DayTypes(d)} SelectedDayIndicator_d \geq 1 \quad \forall\, DayTypes$$

where:

Bins = set of bins in histogram of criteria timeseries

Days = set of days in the historical timeseries

Overall Freq $_b$ = historical frequency of bin across timeseries

Daily Freq $_{d,b}$ = historical frequency in each day

TUNING = tuning parameter value

weight $_d$ = normalized weight for each day

The day sampling process yielded a set of days that show very small deviations from the historical distributions. The details for each of these days—the calendar days used for load, wind, and solar PV, and the associated weight attributed to the day—are shown in Table -1. Figure C-3 shows the comparison of distribution between the full set of candidate days and the representative days.

Table -1. Details for 37 days sampled for operational simulation in RESOLVE

C.2 External Load & Resources

In this study, three MISO Load Resource Zones (LRZ) were modeled to represent Xcel Upper Midwest's interaction with the broader MISO market. The demand forecast for the external zones was based on data from the 2017 MISO Independent Load Forecast Update.[11] The assumed existing and planned resource portfolio was based on MISO's "Continued Fleet Change" in its 2018 MTEP report. The MTEP report only contains data till 2032, so beyond that this study assumes that coal plant retirements are replaced with natural gas combustion turbine generators.

Table C-2, Table C-3, and Table C-4 below show a summary of the load and resource assumptions for the three MISO zones modeled.

1 Background

The Next Generation Energy Act (NGEA), signed in 2007, sets greenhouse gas (GHG) emission targets for Minnesota of 80% reductions by 2050 relative to 2005 levels with interim targets of 15% reductions by 2015 and 30% reductions by 2025.

Xcel Energy Northern States Power (NSP) hired E3 to develop a set of long-term economy-wide, deep decarbonization scenarios for the state of Minnesota. These scenarios provide an exploration of the cross-sectoral implications of meeting economy-wide carbon reduction goals, and highlight the role of Xcel Energy, and the electric sector as a whole, in meeting the state's economy-wide carbon goal.

This report describes background, modeling approach, and results of the Minnesota economy-wide decarbonization scenario analysis. An additional E3 analysis focusing on Xcel Energy NSP system portfolio and reliability, is discussed in a separate report. The geography of each analysis is shown in Figure 1.

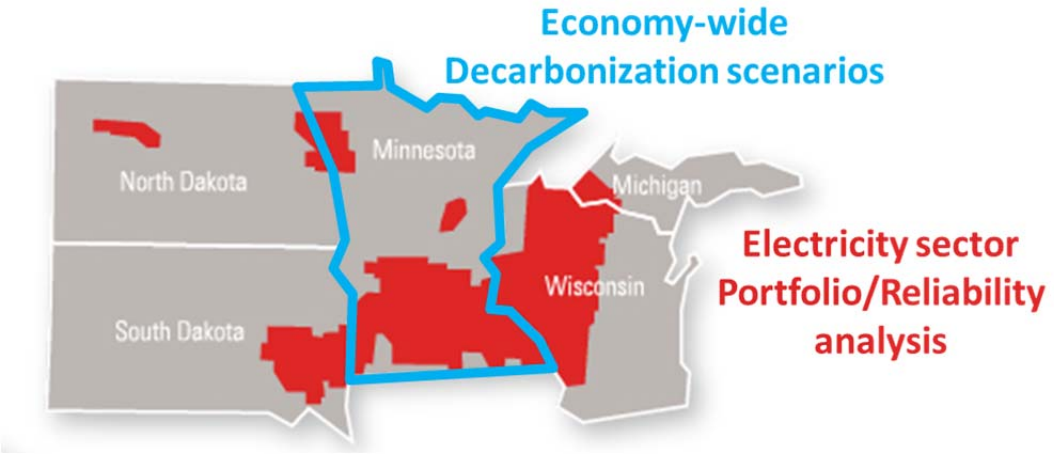

Figure 1. E3 Analysis Geographies for (1) Minnesota economy-wide decarbonization scenarios, and (2) Xcel Energy NSP portfolio and reliability analysis

Figure 2 shows all GHG emissions in the state of Minnesota by sector and subsector.[1] The largest sources of emissions in the state are electricity generation and transportation.[2] This analysis focused on the sectors that are most relevant to an electric utility: electricity generation, transportation, and buildings. Emissions from other sectors (agriculture, industry, and waste) were represented at a high level.

[1] Data pulled from MPCA 2014 GHG Inventory
[2] This work was based on the Minnesota Pollution Control Agency (MPCA) 2014 greenhouse gas inventory. At the time of this report, the MPCA has released updated inventory data through 2016 and transportation is now the largest emitter of GHGs in the state.

Figure 2. Minnesota GHG emissions by category in 2014

2 Approach

2.1 PATHWAYS Model Philosophy

This study used a PATHWAYS model to develop the reference case emission projection. The PATHWAYS model is an economy-wide representation of infrastructure, energy use, and emissions within a specific jurisdiction. The PATHWAYS model represents bottom-up and user-defined emissions accounting scenarios to test "what if" questions around future energy and climate policies. PATHWAYS modeling typically includes the following features:

- Detailed stock rollover in residential, commercial and transportation subsectors
- Interactive effects with electricity demand and electricity supply sectors
- Sustainable biomass feedstock supply curves
- Non-combustion and non-energy emissions

The inclusion of both supply and demand sectors captures interactions between sectors such as increased penetration of electric vehicles and a changing mix of technologies supplying electricity. The focus of the Pathways model is to compare user-defined policy and market adoption scenarios and to track physical accounting of energy flows within all sectors of the economy.

2.2 PATHWAYS in LEAP

E3 built a bottom-up PATHWAYS model of the Minnesota economy using the LEAP tool (Long-range Energy Alternatives Planning system)[3]. This model quantifies the energy and emissions associated with the projected trends in energy use and complementary policies targeting future mitigated emissions. We modeled the period of 2015-2050.

LEAP is an integrated, scenario-based modeling tool that can be used to track energy consumption, production and resource extraction in all sectors of an economy. It can be used to account for both energy sector and non-energy sector greenhouse gas (GHG) emission sources and sinks. LEAP is not a model of a specific energy system, but rather a modeling framework that can be adapted for different jurisdictions.

[3] LEAP is developed by the Stockholm Environment Institute. More information on the LEAP software can be found at www.energycommunity.org

E3 built a model of Minnesota's energy and non-energy emission sources, projecting them through 2050 using different scenarios to understand current trajectories and different pathways that can be reached through complementary policies within the state.

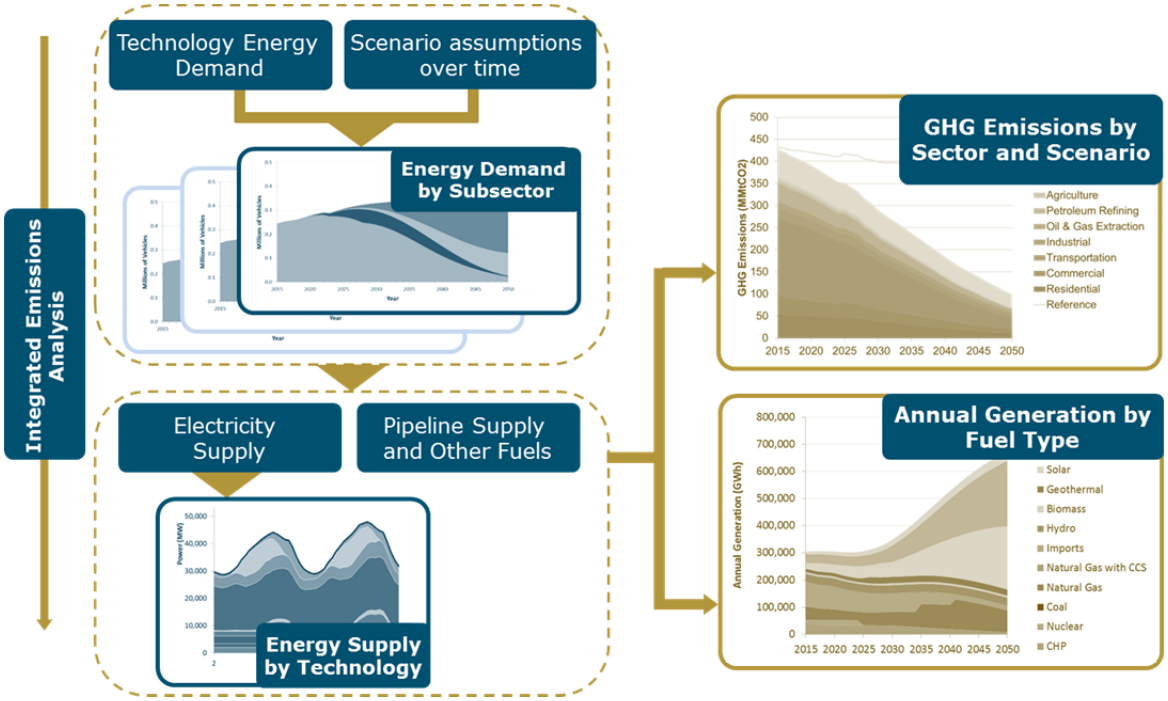

Figure 3. PATHWAYS Energy Modeling Framework

2.3 Scenarios

E3 modeled three scenarios to evaluate a range of emissions reductions from complementary policies.

- **Reference Scenario**: a current policy scenario, including utility-driven energy efficiency, expected adoption of zero emission vehicles, federal fuel economy standards for light-duty vehicles (LDVs)
- **High Electrification Scenario:** a mitigation scenario that includes increased adoption of electric and hydrogen vehicles in medium-duty vehicles (MDVs) and heavy-duty vehicles (HDVs) as well as electric space heating and water heating appliances in buildings.
- **High Biofuels Scenario:** a mitigation scenario that includes lower levels of electrification in favor of higher shares of low-carbon biofuels.

Table 1. Key Assumptions in all scenarios[4]

	Reference Scenario	**High Electrification Scenario**	**High Biofuels Scenario**
Carbon-free electricity generation	48% by 2025, held constant through 2050	48% by 2025, 90% by 2050	
Nuclear power	Retires at end of license	Relicensed or replaced with other carbon-free generation	
Building energy efficiency	50% of appliance sales are high-efficiency by 2030	100% of appliance sales are high-efficiency by 2030 100% adoption of efficient building shell/weatherization measures by 2030 15% reduction in non-stock energy below Reference Scenario by 2030, 30% by 2050 5% reduction in key demands due to smart appliances and conservation by 2030	
Sales of electric heat pump equipment	None	50% by 2030, 100% by 2050, replacing electric, natural gas and LPG	20-30% sales by 2030, replacing only electric and LPG equipment
Zero-emission vehicles	10% of sales by 2030 (Xcel "likely" sales forecast) for LDVs	LDVs: 50% by 2030, 100% by 2050 MDVs: 50% by 2030, 100% by 2050 HDVs: 40% by 2030, 100% by 2050	LDVs: 50% by 2030, 100% by 2050 MDVs: 50% by 2030, 80% by 2050 HDVs: 20% by 2030, 50% by 2050
Vehicle fuel economy	Federal CAFE standards for LDVs by 2026		
Conventional biofuels	20% biodiesel blend in diesel by 2018 (MN239.77); 30% ethanol blend in gasoline by 2025 (MN239.7911)	Transition to advanced biofuels by 2050	
Advanced Biofuels	None	Advanced biofuels without purpose-grown biomass feedstocks	Advanced biofuels with purpose-grown biomass feedstocks
Other sectors (agriculture, waste, industry)	Energy consumption grows at AEO 2017 reference scenario rates by fuel; non-energy GHG emissions held constant at MPCA 2014 Inventory levels	Reduction of 64% below 2005 GHG Emissions by 2050	Reduction of 69% below 2005 GHG Emissions by 2050

[4] More detailed assumptions are included in the sections that follow

In addition to mitigation scenarios, we developed three sensitivities to test the impact on emissions of federal action and consumer adoption. The three sensitivities were defined as follows and are documented further in Section 3.2.4:

1. **Efficiency, Electrification, and Clean Electricity Only**: Evaluates the impact of only pursuing building efficiency, high adoption of electric vehicles and household devices, and clean electricity towards meeting GHG targets
2. **No CAFE Extension**: Evaluates the impact of EPA's proposal to freeze federal Corporate Average Fuel Economy (CAFE) standards at 2020 levels.
3. **Lower Electric Adoption**: Evaluates the combined impact of lower consumer adoption of electric vehicles and electric household devices.

2.4 Inputs

To populate the Minnesota PATHWAYS model, we focused on in-state data sources where possible, supplementing with national data sets to fill remaining data gaps. Specific inputs are listed below.

2.4.1 FIRST YEAR EMISSIONS BENCHMARKING

In 2014, Minnesota had a population of 5.45 Million people residing in 2.1 Million households.[5] In each sector of the economy, we create a representation of a base year (2014) of infrastructure and energy, and then identify key variables that drive activity change over the duration of each scenario (2015-2050). Table 2 shows emissions benchmarking from the MN PATHWAYS model created for this analysis and the Pollution Control Agency (PCA) 2014 GHG Inventory.

[5] Source: Minnesota State Demographic Center

Table 2. Emissions Benchmarking in Minnesota PATHWAYS model to Minnesota PCA GHG inventory in 2014. MST = million short tons.

Sector	MPCA 2014 [MST CO2e]	PATHWAYS 2014 [MST CO2e]	Difference [MST CO2e]	Difference [%]
Buildings	19.0	19.0	0.0	0%
Transportation	39.1	39.2	0.1	0%
Electricity Generation	46.7	46.6	0.0	0%
Other	53.4	53.4	0.0	0%
Total	**158.2**	**158.2**	**0.0**	**0%**

2.4.2 KEY DRIVERS AND DEMOGRAPHICS

Each sector includes assumptions about key drivers of activity within that sector. Table 3 identifies the key drivers behind each sector's energy consumption in the reference scenario. Additional detail is available in the sections that follow.

Table 3. Key Drivers by PATHWAYS Sector in the Reference Scenario

Sector	**Key Driver**	**Compound annual growth rate [%]**	**Data Source**
Buildings	Population	0.44%	MN State Demography Center
Industry	Energy growth	Varies by fuel	EIA AEO 2018 growth rates (2018-2050)
On Road Transportation	Vehicle-miles traveled (VMT)	0.5% LDV 1.3% MDV 1.2% HDV	EIA AEO 2018
Off Road Transportation	Energy growth	Varies by fuel	EIA AEO 2018 growth rates (2018-2050)
Electricity Generation	Electric load growth	-0.1% average 2015-2030 (0.2% 2015-2050)	Built up from Pathways demands in Buildings, Industry, Transportation

The sections that follow will detail scenario assumptions for each key sector in the Minnesota PATHWAYS model.

2.4.3 BUILDINGS SECTOR

2.4.3.1 Base Year

The Minnesota LEAP model includes a stock-rollover representation of 17 residential and 10 commercial building subsectors, including space heating, water heating, and lighting. Sectoral energy demand is benchmarked to energy consumption by fuel from the Minnesota GHG inventory for 2014 and is disaggregated by subsector based on the EIA National Energy Modeling System (NEMS) technology characterization. All residential and commercial subsectors are listed in Table 4.

Table 4. Representation of 2014 Building Energy Consumption by Subsector in Minnesota

Sector	Subsector	Modeling Approach	Energy Use in 2014 [Tbtu]	Percent of 2014 Energy Use [%]
Residential	Central Air Conditioning	Stock Rollover	3.2	1%
	Room Air Conditioning	Stock Rollover	0.2	0%
	Building Shell	Stock Rollover	-	0%
	Clothes drying	Stock Rollover	4.7	1%
	Clothes washing	Stock Rollover	0.7	0%
	Cooking	Stock Rollover	5.7	1%
	Dishwashing	Stock Rollover	1.9	0%

	Reflector Lighting	Stock Rollover	0.8	0%
	General Service Lighting	Stock Rollover	3.7	1%
	Exterior Lighting	Stock Rollover	0.6	0%
	Linear fluorescent lighting	Stock Rollover	0.6	0%
	Single Family Space Heating	Stock Rollover	103.6	23%
	Multi Family Space Heating	Stock Rollover	16.3	4%
	Refrigeration	Stock Rollover	7.7	2%
	Water heating	Stock Rollover	43.2	10%
	Residential Other*	Total Energy by Fuel	59.2	13%
Commercial	Air conditioning	Stock Rollover	1.9	0%
	Cooking	Stock Rollover	15.9	4%
	General service lighting	Stock Rollover	7.0	2%
	High intensity discharge lighting	Stock Rollover	7.5	2%
	Linear fluorescent lighting	Stock Rollover	7.6	2%
	Refrigeration	Stock Rollover	3.5	1%
	Space heating	Stock Rollover	66.5	15%
	Ventilation	Stock Rollover	9.5	2%
	Water Heating	Stock Rollover	7.5	2%
	Commercial Other*	Total Energy by Fuel	64.2	14%
All Building Sectors			**444.7**	**100%**

*Residential Other includes furnace fans, plug loads (e.g. computers, phones, speakers, printers), secondary heating, fireplaces, and outdoor grills. Commercial Other includes plug loads, office equipment, fireplaces, and outdoor grills.

2.4.3.2 Reference Scenario

The primary reference measure represented in buildings is the achievement of electric energy efficiency. Energy efficiency in buildings is implemented in the PATHWAYS model in one of three ways:

1. As new appliance or lighting end use technology used in the residential and commercial sectors (e.g., a greater share of high efficiency appliances is assumed to be purchased). New equipment is typically assumed to replace existing equipment "on burn-out", e.g., at the end of the useful lifetime of existing equipment.

2. As a reduction in energy services demand, due to smart devices (e.g. programmable thermostats), conservation, or behavior change.

3. For the sectors that are not modeled using specific technology stocks (Residential Other and Commercial Other), energy efficiency is modeled as a reduction in total energy demand.

Table 5. Reference Scenario Assumptions for Building Energy Efficiency

Category of Building Measures	Reference Scenario Assumption
Building retrofits for high efficiency building shells	None
New appliance sales	50% of new sales of all appliances are assumed to be efficient (e.g. EnergyStar) by 2030. See Figure 4.
Building electrification	None
Behavioral conservation and smart devices	None
Other non-stock sectors	None

Since the model is based on a bottom-up forecast of technology stock changes in the residential and commercial sectors, the model does not use a single load forecast or energy efficiency savings forecast as a model input. It is important to note that the modeling assumptions used in this analysis may not reflect specific future energy efficiency programs or activities.

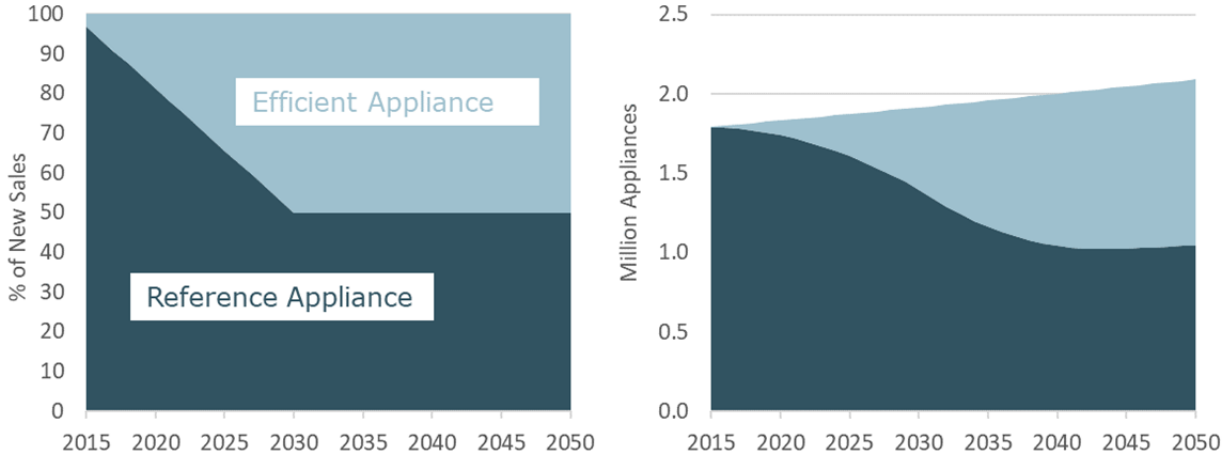

Figure 4. Assumed New Sales for Building Appliances (left) and Resulting Appliance Stocks (right), Reference Scenario

2.4.3.3 Mitigation Scenarios

Each Mitigation Scenario includes more aggressive energy efficiency and electrification in buildings. The High Electrification Scenario assumes more ambitious adoption of electric heat pumps for space heating and water heating, while the High Biofuels Scenario assumes electric heat pumps displace only existing electric and LPG equipment. See Table 6 for a full list of assumptions.

Table 6. Mitigation Scenario Assumptions for Building Energy Efficiency

Category of Building Measures	**High Electrification Scenario**	**High Biofuels Scenario**
Building retrofits for high efficiency building shells	100% adoption of efficient building shell and weatherization measures by 2030	
New appliance sales	100% of new sales of all appliances are assumed to be efficient (e.g. EnergyStar) by 2030.	
Building electrification	50% sales of electric heat pumps by 2030, 95% by 2050, replacing electric, natural gas and LPG systems	20-30% sales of electric heat pumps by 2030, replacing only electric and LPG equipment
Behavioral conservation and smart devices	10% reduction in energy services demand below Reference Scenario in residential lighting, space heating, and water heating	
Other non-stock sectors	30% reduction in energy consumption below Reference Scenario by 2050	

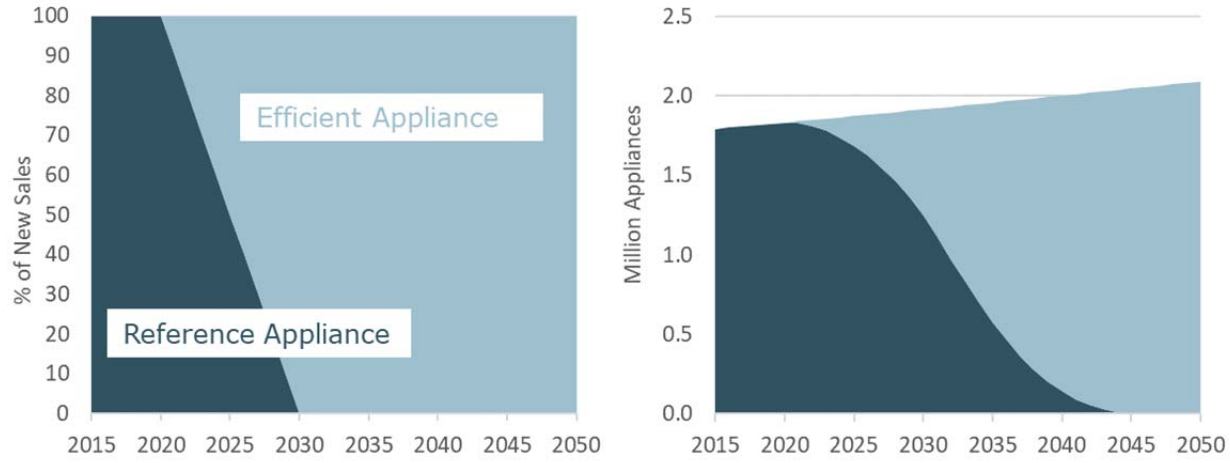

Figure 5. Assumed New Sales for Building Appliances (left) and Resulting Appliance Stocks (right), High Electrification Scenario

A key assumption across our scenarios is the adoption of high efficiency electric heat pumps for space heating and water heating. Currently in Minnesota electric heat pumps make up less than one percent of space heaters and water heaters.

In the High Biofuels Scenario we assume a shift to heat pump space heaters (20-30% of new sales by 2030), displacing sales of existing electric and LPG equipment. In the High Electrification Scenario, we assume significant adoption of heat pumps for both space heating and water heating, reducing sales of natural gas, existing electric, and LPG systems. The total number of electric heat pump space heaters in Minnesota residences is reported in Figure 6.

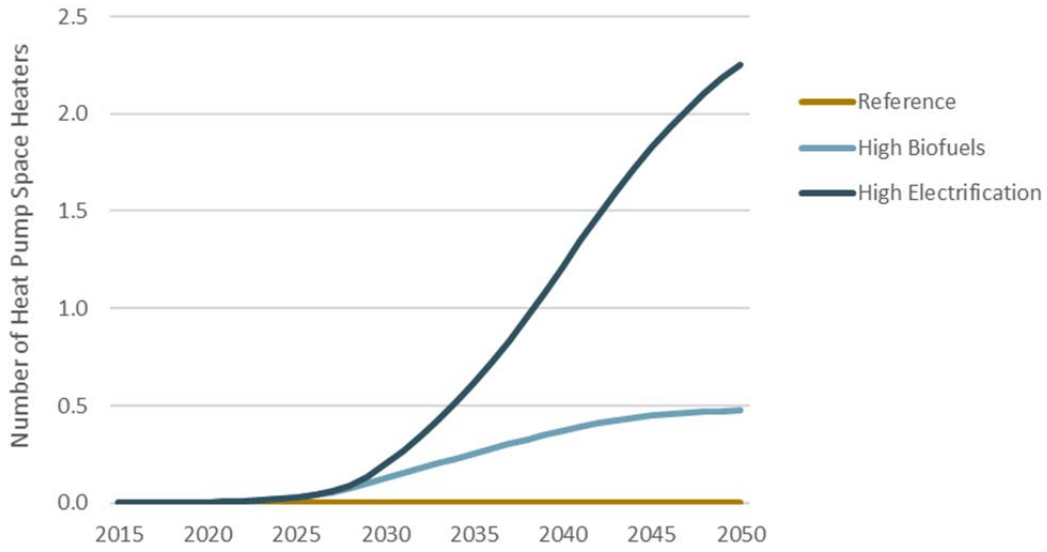

Figure 6. Total number of residential electric heat pump space heaters in all scenarios.

2.4.4 TRANSPORTATION SECTOR

2.4.4.1 Base Year

The Minnesota LEAP model includes a stock-rollover representation of four transportation sectors and an energy representation of six subsectors. Sectoral energy demand is benchmarked to energy consumption by fuel from the Minnesota GHG inventory for 2014 and is disaggregated by subsector based on the EIA National Energy Modeling System (NEMS) technology characterization and additional data from PCA. All subsectors represented in the transportation sector are listed in Table 7.

Table 7. Transportation 2014 Subsector Energy Consumption in Minnesota

Sector	Subsector	Modeling Approach	Estimated Energy Use in 2014 [TBtu]	Estimated % of 2014 Energy Use [%]
Light Duty Vehicles	Light Duty Autos	Stock Rollover	128	26%
	Light Duty Trucks	Stock Rollover	148	30%
Medium Duty Vehicles	Medium Duty Trucks	Stock Rollover	71	14%
Heavy Duty Vehicles	Heavy Duty Trucks	Stock Rollover	74	15%
Transportation Other	Aviation	Total Energy by Fuel	46	9%
	Rail	Total Energy by Fuel	15	3%
	Motorcycles	Total Energy by Fuel	3	1%
	Bus	Total Energy by Fuel	4	1%
	Military and Off-Highway	Total Energy by Fuel	7	1%
	Marine	Total Energy by Fuel	4	1%
All Transportation Sectors			**501**	**100%**

2.4.4.2 Reference Scenario

Two key measures were represented in the Minnesota PATHWAYS Reference Scenario: (1) Federal Light Duty Vehicle (LDV) Corporate Average Fuel Economy (CAFE) Standards, and (2) expected sales of zero-emission vehicles (ZEVs) in Minnesota. LDV CAFE Standards are represented in the marginal fuel economy of new gasoline vehicles sold in addition to an increased share of ZEVs sold. Increasing marginal fuel economy assumed is shown in Figure 7 for light-duty automobiles (LDA) and light-duty trucks (LDT).

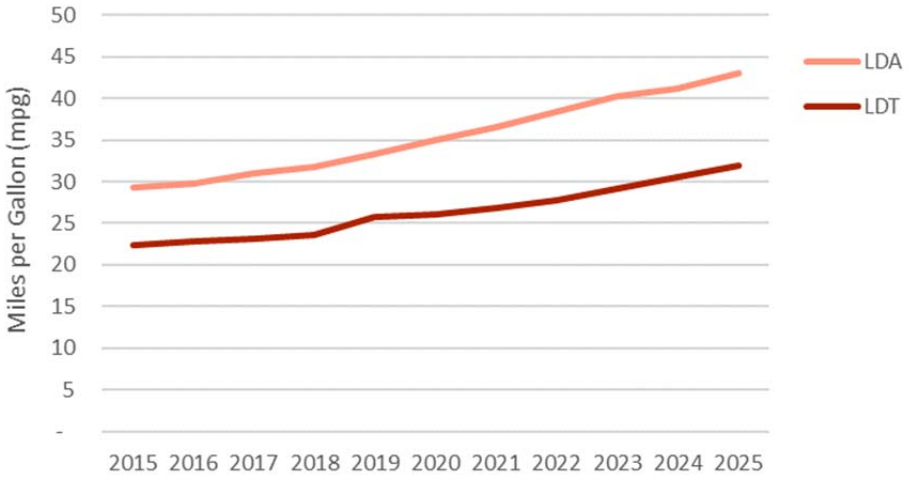

Figure 7. Marginal Fuel Economy for Gasoline LDVs in Minnesota

The second key measure, expected ZEVs in Minnesota, is represented through increasing sales of plug-in hybrid vehicles (PHEVs) and battery electric vehicles (BEVs) over time. We used Xcel Energy's "likely" sales of BEVs for their service territory and assumed that for the state of Minnesota. We assume that new sales increase linearly to be 20% ZEV sales by 2020. In our stock rollover methodology, this means that of all the cars that are purchased in 2020 (either due to retirement or new growth), 15% will be battery electric vehicles and 5% will be plug-in hybrid electric vehicles. This assumption is shown for light duty autos (LDAs) and light duty trucks (LDTs) in Figure 8. No changes were assumed in the heavy-duty fleet.

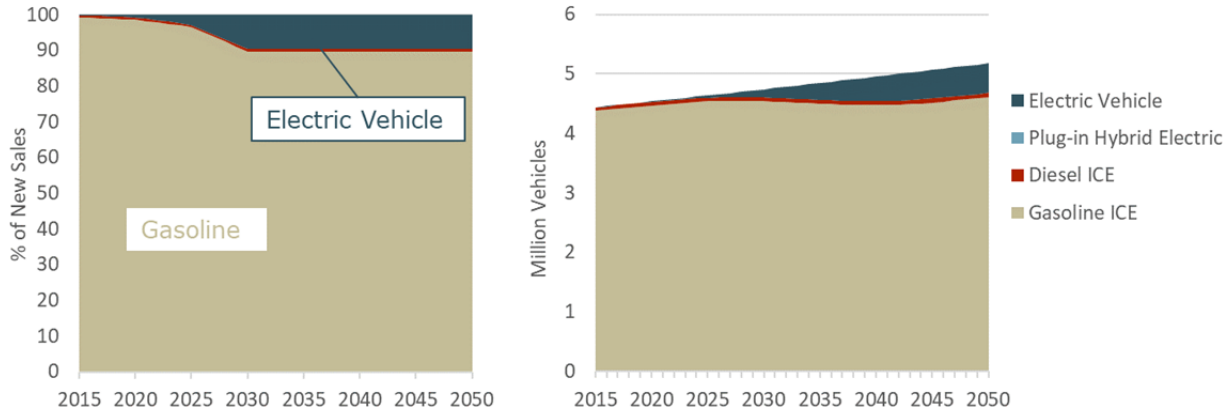

Figure 8. Assumed new light duty vehicle sales (left) and resulting stocks (right), Reference Scenario

In other subsectors of transportation, total energy consumption in Table 7 was assumed to grow at EIA AEO 2018 growth rates by fuel.

2.4.4.3 Mitigation Scenarios

Both Mitigation Scenarios assume significant reductions in light-duty vehicle-miles traveled (VMT), which could be achieved through urban design, transportation demand management, or mode shifting. Both scenarios assume aggressive electrification in light duty vehicles, up to 100% of new sales in 2050, representing no internal combustion vehicles being sold after that year. The High Electrification Scenario includes more aggressive zero-emission vehicle sales in medium- and heavy-duty vehicles, reaching 100% of new sales by 2050. The High Biofuels Scenario includes lower adoption of ZEVs in medium- and heavy-duty vehicles, where biofuels are assumed to be blended into transportation fuels.

Table 8. Mitigation Scenario Assumptions for Transportation

Category of Transportation Measures	High Electrification Scenario	High Biofuels Scenario
Vehicle Miles Traveled (VMT) reductions in light duty vehicles	Annual VMT is reduced by 15% below Reference by 2050	
Zero-emission Light Duty Vehicle (LDV) sales	50% sales by 2030, 100% by 2050	
Zero-emission Medium Duty Vehicle (MDV) sales	50% by 2030, 100% by 2050	50% by 2030, 80% by 2050
Zero-emission Heavy Duty Vehicle (HDV) sales	50% by 2030, 100% by 2050	20% by 2030, 50% by 2050
Aviation efficiency	Reduction in energy use of 40% below Reference Scenario by 2050	
Transportation Other	AEO 2018 reference scenario growth rates by fuel	

Assumptions for total new sales of light-duty vehicles and resulting total stocks is shown in Figure 9.

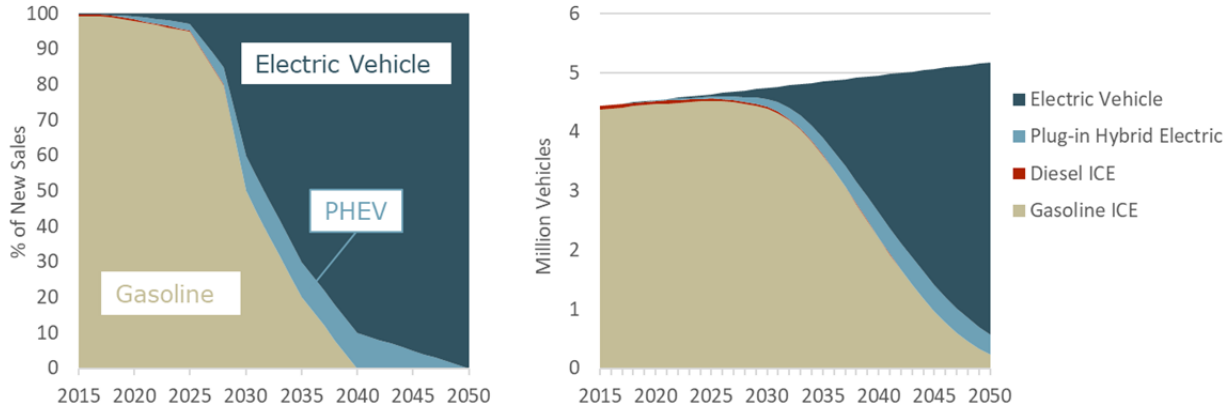

Figure 9. Assumed new light duty vehicle sales (left) and resulting stocks (right), High Electrification and High Biofuels Scenario

2.4.5 ELECTRICITY SECTOR

The Minnesota PATHWAYS model contains a dedicated branch for modeling electricity generation. Operations in the electricity sector are modeled on an annual basis, based on projected changes in electric capacity, generation, and changes in load. More detailed analysis of capacity expansion and operations for Xcel Energy Northern States Power were modeled in a parallel project with E3's RESOLVE and RECAP models.

2.4.5.1 Base Year

In-state generation capacity for Minnesota resources is based on EIA. Assumed generation by resource is shown in Table 9.

Table 9. Minnesota Electricity Generation in 2014[6]

Resource	Generation [TWh]	Share of 2014 Generation [%]
Nuclear	12.7	17%
Coal	28.0	38%
Natural Gas	3.9	5%
Oil	0.1	0%
Hydro	0.5	1%
Biomass	2.2	3%
Onshore Wind	9.7	13%
Utility Solar	0.0	0%
Net Imports	15.7	22%
Total	**72.7**	**100%**

2.4.5.2 Reference Scenario

In the Minnesota PATHWAYS model, total electricity demand is calculated from independent assumptions in each demand sector (buildings, transportation, industry, and agriculture). This approach ensures that we take into account linkages between sectors so that our generation and emissions from the electric sector are aligned with electrification loads in our mitigation scenarios. The Minnesota PATHWAYS model simulates dispatch of in-state generators and imported power from the Midcontinent Independent System Operator (MISO) to meet electricity demands in each year based on assumed percent shares of generation coming from generator types. All scenarios include an assumption of 6% transmission and distribution losses.

In the Reference Scenario, we assume that in-state nuclear facilities retire at the end of their license and are replaced with imported power. We assume moderate reductions in coal generation to reflect planned utility retirements. Table 10 shows the assumed share of electricity generation by resource.

Table 10. Assumed share of electricity generation by resource type, Reference Scenario

	2020	2030	2040	2050
Carbon-Free Generation*	43.6%	49.8%	33.7%	33.7%
Natural Gas	7.1%	10.0%	10.0%	10.0%
Oil	0.1%	0.1%	0.1%	0.1%
Coal	33.9%	30.0%	30.0%	30.0%

[6] US Energy Information Administration, Minnesota Electricity Profile, Table 5, full data available online: https://www.eia.gov/electricity/state/minnesota/index.php

Net Imports	15.3%	10.1%	26.2%	26.2%
Total	100.0%	100.0%	100.0%	100.0%

*Carbon-Free Generation includes utility-scale solar, onshore wind, biomass, hydro-electric, and nuclear generators

2.4.5.3 Mitigation Scenarios

Each Mitigation Scenario assumes significant ramp up of carbon-free generation over the next 30 years. Both Mitigation Scenarios are designed to meet the same share of carbon-free electricity by 2050, as shown in Table 11.

Table 11. Assumed share of electricity generation by resource type, Mitigation Scenarios

	2020	2030	2040	2050
Carbon-Free Generation*	42.5%	56.2%	73.6%	90.0%
Natural Gas	5.3%	5.3%	5.3%	5.3%
Oil	0.1%	0.0%	0.0%	0.0%
Coal	31.5%	20.0%	10.0%	0.0%
Net Imports	20.6%	18.4%	11.1%	4.7%
Total	100.0%	100.0%	100.0%	100.0%

*Carbon-Free Generation includes utility-scale solar, onshore wind, biomass, hydro-electric, and nuclear generators

Even though both scenarios have the same share of generation being met by carbon-free electricity, total generation is very different due to assumptions about electrification, as shown in Figure 10.

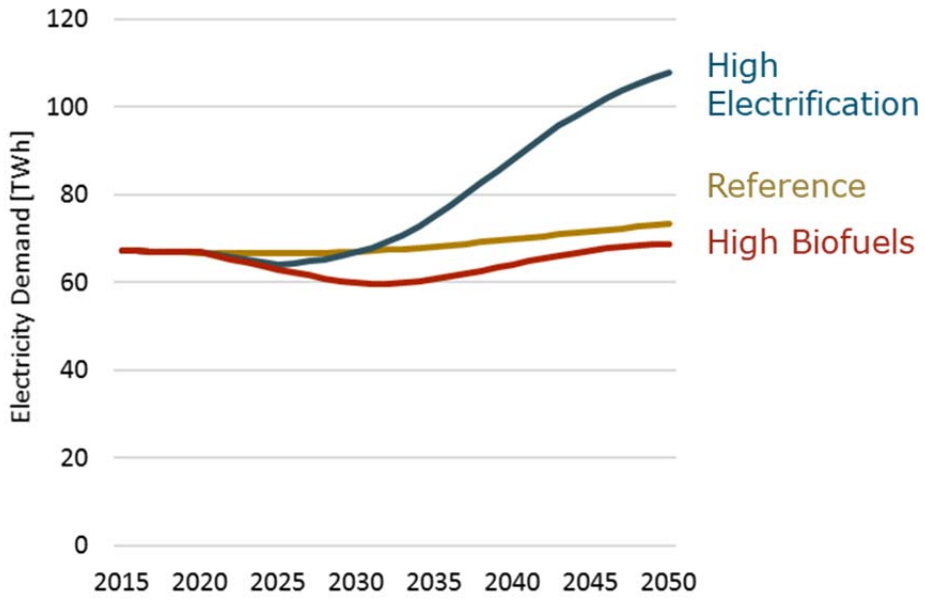

Figure 10. Electricity demand by scenario

2.4.6 BIOFUEL SUPPLY

The decarbonization transition will require strategic use of limited biomass and careful screening of sustainable feedstocks to ensure that bioenergy produces zero carbon emissions and is sustainably grown without producing adverse land-use impacts. Examples of biomass products that are used to produce biofuels include corn, soybeans, sugar cane, forest products, manure, switch grass and other agricultural waste products, such as corn stover.

Minnesota has a robust conventional biofuels industry that produces ethanol (from corn) and biodiesel (from soy and other waste oils). Our Reference Scenario assumes continued growth of the conventional biofuels industry, while our Mitigation Scenarios assume a transition after 2030 to an advanced biofuels industry. Note that both conventional biofuels and advanced biofuels are treated as having zero carbon emissions at the point of combustion from the Minnesota PCA Inventory accounting.

New sustainable biomass feedstock assessments are taken from the 2016 DOE Billion Ton Study (BTS) Update[7], which estimates sustainable yield of a variety of raw biomass sources, including agricultural (including dedicated energy crops), forestry (including new forests and residues), and waste streams (including municipal waste and forest residues).

2.4.6.1 Reference Scenario

The Reference Scenario assumes compliance with current targets for conventional ethanol and biodiesel. For ethanol, we assume a 30% blend of ethanol in motor gasoline by 2025.[8] For biodiesel we include the seasonal Minnesota B20 mandate, modeled as a 10% blend of biodiesel for the whole year.[9]

2.4.6.2 Mitigation Scenarios

In our Mitigation Scenarios, we assume a transition from conventional biofuel blends in the next 10 years to advanced biofuel production by 2050.

To determine available sustainable biomass supply through our study period, we assumed that Minnesota would have access to its population-weighted share of the total national feedstock supply, which is about 2% of the total supply. This approach assumes that all US states begin to transition to developing advanced biofuels with these resources. Minnesota has more biomass feedstocks within the state than its population-weighted share, which indicates that Minnesota would be able to sell excess biofuel products into a national market.

Figure 11 shows the national estimated biomass feedstock supply. The High Biofuel Scenario assumes that both residues and energy crops are available, while the High Electrification Scenario assumes only residue categories are available. The “Residues” category includes agricultural residues, food waste, forest residues, municipal solid waste, and manure. Residue feedstocks have fewer concerns about land-use constraints and competition with food crops.

[9] 239.77 Biodiesel Content Mandate: https://www.revisor.mn.gov/statutes/cite/239.77

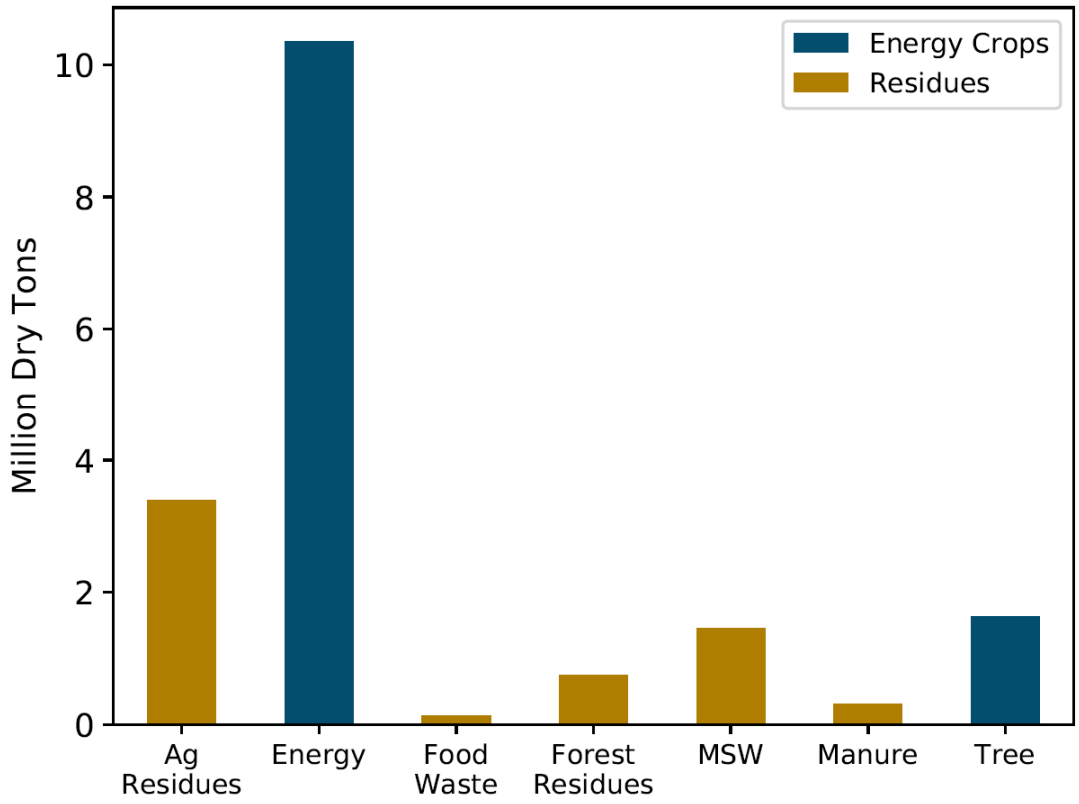

Figure 11. Minnesota Biomass Feedstock Supply by 2040 by Resource Category

To calculate the optimal portfolio of biofuels, E3 has developed a model which generates biofuel supply curves that determine the availability and cost of renewable liquid and gaseous fuels. The model optimizes the selection of combinations of feedstocks and conversion pathways. The model adds preparation, process, transportation, and delivery costs to BTS feedstock cost curves to achieve supply curves by feedstock and conversion pathway. To obtain biofuel demand, we apply the percentage biofuel penetration targets to aggregate calculated final energy demand.

Figure 12 shows the total resulting advanced biofuel consumption by fuel for each scenario. Because the High Biofuels Scenario includes feedstocks from energy crops and dedicated forests, that scenario is able to use more than two times the total quantity of biofuels than the High Electrification Scenario, which is limited to wastes and residues.

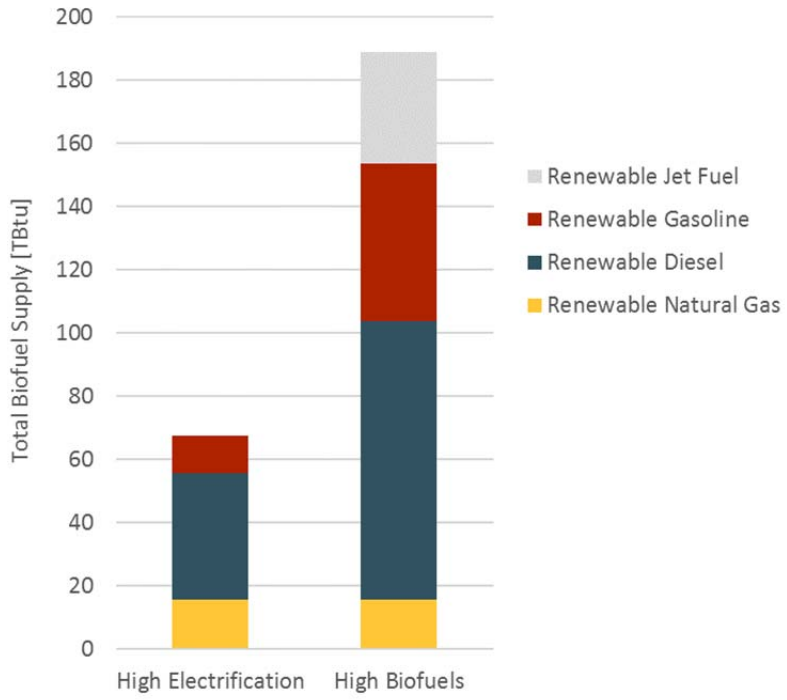

Figure 12. Total Advanced Biofuel Production by Biofuel in 2050, Mitigation Scenarios

Figure 12 highlights a different view of the same result, showing total consumption of gasoline, diesel, and natural gas by the share that is blended biofuel (and therefore zero-carbon) and the remaining share that is fossil.

2.4.7 OTHER SECTORS

This analysis focused in detail on the electricity generation, transportation, and buildings sectors. Additional sectors not modeled in significant detail are the agriculture, industry, and waste sectors.

2.4.7.1 Base Year

All energy consumption in industry, agriculture, and waste is represented as total annual energy consumption by fuel, as shown in Table 12.

Table 12. Energy Consumption in Industry, Agriculture, and Waste sectors by fuel in Minnesota, 2014

Sector	Fuel	Modeling Approach	Estimated Energy Use in 2014 [Tbtu]	Estimated % of 2014 Energy Use [%]
Industry (All Subsectors)	Electricity	Total Energy by Fuel	78.7	21%
	Gasoline	Total Energy by Fuel	2.7	1%
	Residual Fuel Oil	Total Energy by Fuel	0.1	0%
	Coal	Total Energy by Fuel	19.0	5%
	Petroleum Coke	Total Energy by Fuel	1.6	0%
	Refinery Feedstocks	Total Energy by Fuel	18.7	5%
	Wood	Total Energy by Fuel	27.2	7%
	Natural Gas	Total Energy by Fuel	154.1	41%
	LPG	Total Energy by Fuel	0.0	0%
	Diesel	Total Energy by Fuel	39.0	10%
	Renewable Diesel	Total Energy by Fuel	1.7	0%
	Coal Coke	Total Energy by Fuel	0.6	0%
Agriculture (All Subsectors)	Electricity	Total Energy by Fuel	-	0%
	Gasoline	Total Energy by Fuel	3.3	1%
	Natural Gas	Total Energy by Fuel	-	0%
	LPG	Total Energy by Fuel	10.5	3%
	Diesel	Total Energy by Fuel	16.4	4%
	Renewable Diesel	Total Energy by Fuel	0.7	0%
Waste (All Subsectors)	Natural Gas	Total Energy by Fuel	0.3	0%
	Diesel	Total Energy by Fuel	0.4	0%
	Renewable Diesel	Total Energy by Fuel	0.0	0%
All Sectors			**374.8**	**100%**

Additional non-energy emissions in industry, agriculture, and waste sectors were represented as total annual emissions, as shown in Table 13.

Table 13. Non-Energy Emissions in Industry, Agriculture, and Waste sectors in Minnesota, 2014

Sector	Fuel	Modeling Approach	Estimated Emissions 2014 [MST CO2e]	Estimated % of 2014 Non-Energy Emissions [%]
Agriculture	Animals	Total emissions	10.1	30%
	Crops	Total emissions	16.4	49%
	Other	Total emissions	0.0	0%
Industrial	Coal Storage	Total emissions	0.0	0%
	Industrial Process	Total emissions	0.6	2%
	Industrial Other	Total emissions	0.0	0%
	Oil Refining	Total emissions	0.0	0%
	Refinery Processes	Total emissions	1.7	5%
	Semiconductor Manufacture	Total emissions	0.3	1%
	Taconite Induration	Total emissions	2.1	6%
Waste	Industrial Landfills	Total emissions	0.1	0%
	Landfill gas combustion and flaring	Total emissions	0.0	0%
	MMSW Landfills	Total emissions	2.1	6%
	Medical	Total emissions	0.0	0%
	Rural Open Burning	Total emissions	0.0	0%
	Sludge	Total emissions	0.0	0%
	Waste Processing	Total emissions	0.2	1%
	Waste Solvent	Total emissions	0.0	0%
	Wastewater Treatment	Total emissions	0.4	1%
	Yard Waste Composting	Total emissions	0.0	0%
	Sequestration in landfills	Total emissions	-0.6	-2%
Total			33.7	100%

2.4.7.2 Reference Scenario

In the Reference Scenario, all energy consumption is assumed to grow at EIA AEO 2018 growth rates by fuel. All non-combustion emissions are held constant at 2014 levels.

2.4.7.3 Mitigation Scenarios

The overall approach for Mitigation Scenarios is to first calculate emission reductions from other sectors, and then to calculate the required reduction from remaining sectors in order to hit economy-wide NGEA goals by 2050. In both scenarios, we find that industry, agriculture, and waste sectors require a reduction that is lower than that in buildings, transportation, and electricity generation. This might be a fair assumption if it would be more expensive to decarbonize these sectors or if new technologies and measure would take longer to ramp up. The one specified assumption is that in the High Electrification Scenario, we assumed half of agricultural equipment could be electrified by 2050. Mitigation Scenario assumptions for other sectors are documented in Table 15.

Table 14. Mitigation Scenario Assumptions for Industry, Agriculture, Waste, and Non-Combustion Emissions

Category of Other Measures	**High Electrification Scenario**	**High Biofuels Scenario**
Electrification	50% of agricultural equipment energy use was assumed to be electrified by 2050.	None
Emissions Reductions for All Sectors below 2005 Levels	64%	69%

3 Results

3.1 GHG Emissions

Based on the assumptions outlined in Section 2 above, GHG emissions are calculated for Minnesota as shown in Figure 13. In the Reference Scenario, emission reductions are achieved in the initial years due to energy efficiency in buildings and transportation, as well as cleaner electricity generation. Emissions begin to rise after current policies no longer have an incremental effect and increased population and economic activity continue to increase energy use. Mitigation Scenarios fall short of the 2025 goal but meet the 2050 NGEA target.

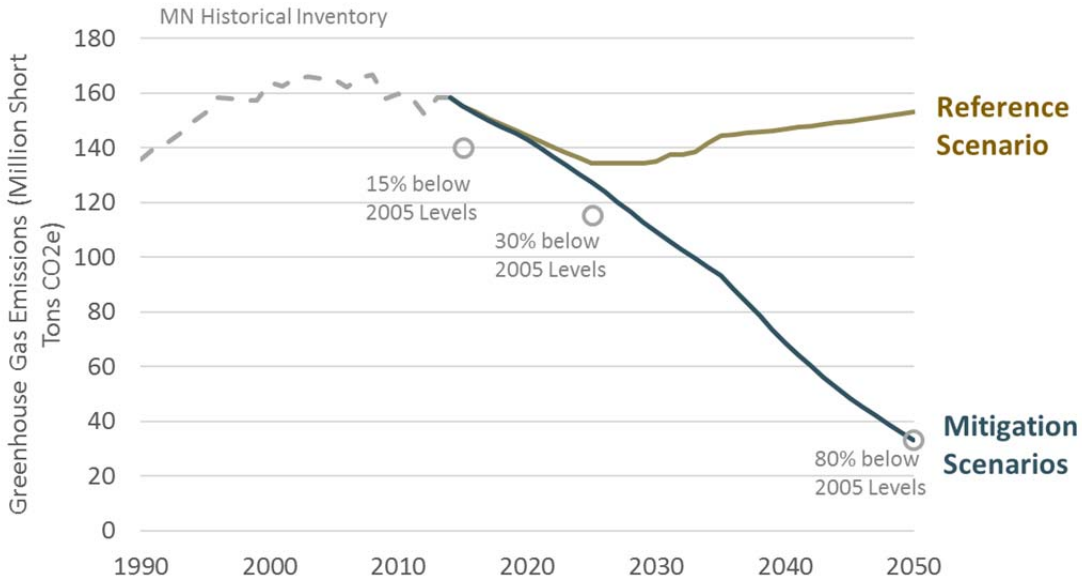

Figure 13. Minnesota GHG Emissions Results for Reference Scenario, 2015-2050

Emissions by Scenario are shown in Table 15 below.

Table 15. Total GHG Emissions by Scenario [Million Short Tons CO2e]

	2015	2020	2025	2030	2035	2040	2045	2050
Reference Scenario	155	144	134	135	144	147	150	153
High Electrification Scenario	155	143	127	109	93	69	48	33
High Biofuels Scenario	155	143	127	108	93	71	50	33
NGEA GHG Goals	140		115					33

Emissions for each modeled sector are shown over time in Figure 14 in the Reference Scenario. The largest direct reductions are in electricity generation, due to the retirement of in-state coal units and reduced demand due to efficiency, and transportation, due to federal CAFE standards and increased sales of ZEVs.

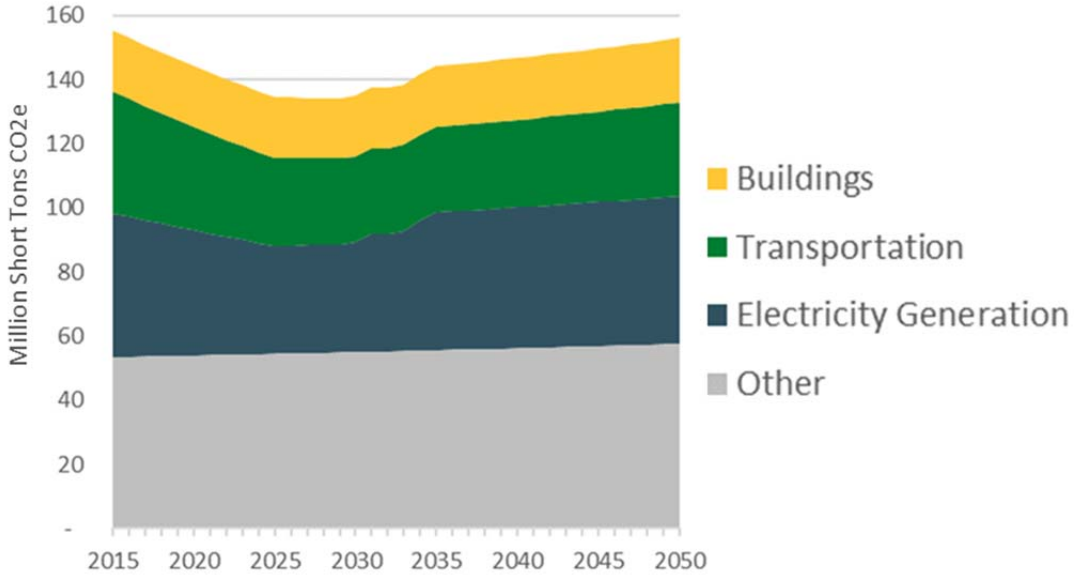

Figure 14. Minnesota GHG Emissions by Sector in the Reference Scenario, 2015-2050[10]

Emissions reductions by sector for each mitigation scenario is shown in Figure 15 and Increased electrification in the High Electrification scenario requires fewer reductions in "Other" sectors, but increases electricity generation demands, allowing for greater reductions in the High Biofuels Scenario.

Table 16. The High Electrification Scenario shows significant reductions in buildings and transportation due to adoption of electric appliances. The High Biofuels Scenario achieves fewer reductions in buildings and greater reductions in transportation due to allocating increased biofuels largely to on road vehicles.

[10] Other includes Agriculture, Industry, and Waste emissions

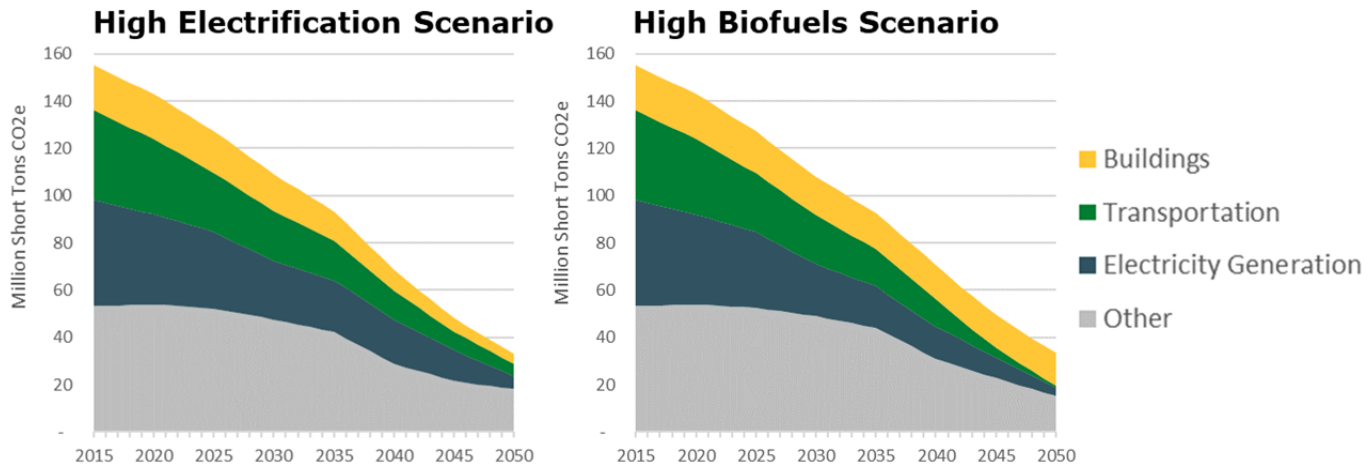

Figure 15. Minnesota GHG Emissions by Sector in Mitigation Scenarios, 2015-2050

Increased electrification in the High Electrification scenario requires fewer reductions in "Other" sectors, but increases electricity generation demands, allowing for greater reductions in the High Biofuels Scenario.

Table 16. GHG Reductions in Mitigation Scenarios in 2050 relative to 2005 emissions by sector

	High Electrification Scenario	High Biofuels Scenario
Buildings	-74%	-14%
Transportation	-87%	-98%
Electricity Generation	-91%	-94%
Other	-64%	-69%
Total	**-80%**	**-80%**

3.2 Sectoral Findings

3.2.1 BUILDINGS

The focus of measures in buildings is on energy efficiency and electrification. Increased sales of more efficient appliances and devices result in increased stock of those devices over time as old devices retire. Increased sales of efficient devices along with behavioral conservation and reductions in non-stock energy consumption results in significant reductions in total energy consumption as shown in Figure 16. Both scenarios achieve significant energy efficiency relative to the Reference Scenario, but the High Electrification Scenario achieves greater reductions in final energy consumption due to switching from natural gas appliances to more efficient electric heat pumps. Figure 16 also breaks out the impact of conventional efficiency and efficiency through electrification. The section between the black and grey

lines highlights the reduction in building energy consumption from measures like improved device efficiency, improved building shell (e.g. insultation), and smart devices. The section below the grey line highlights the additional reduction in energy consumption from switching to high-efficiency electric heat pump technologies in space heating and water heating.[11]

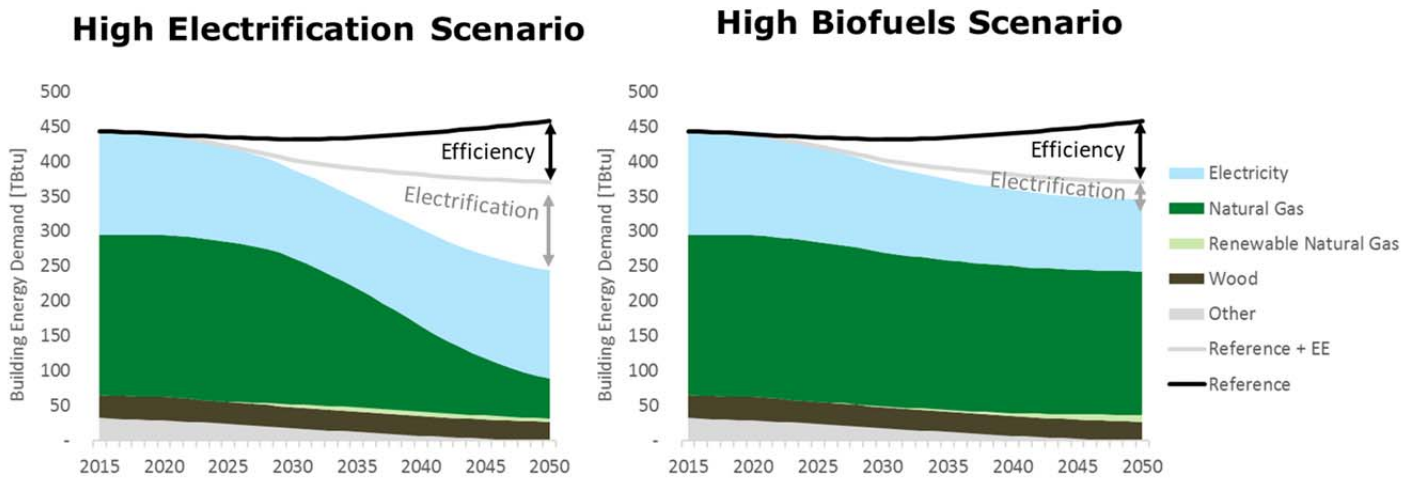

Figure 16. Total energy consumption by fuel and scenario in buildings

3.2.2 TRANSPORTATION

Reductions in emissions in the transportation sector are achieved through efficiency, electrification, and biofuels. Energy efficiency is included in two forms: (1) federal CAFE standards for new vehicle sales, and (2) VMT reductions due to transit and smart growth measures. New sales of vehicles with more efficient electric drive trains achieve significant efficiency and the potential to reduce emissions further by consuming cleaner electricity. Benefits of displacing fossil fuels with renewable diesel, renewable gasoline, and renewable jet fuel further reduces emissions within the transportation sector.

Figure 17 highlights the impacts of energy efficiency on total final energy demand in transportation. Both Mitigation Scenarios show significant reductions in total energy consumption relative to the Reference Scenario due to reductions in vehicle miles traveled and more efficient electric drive trains. In the High Electrification Scenario, hydrogen fuel cell heavy-duty trucks and electric medium-duty trucks are used. In the High Biofuels Scenario, advanced biofuels displace all remaining petroleum fuels by 2050.

[11] Note that these scenarios do not include a detailed analysis of electric heat pump performance in Minnesota.

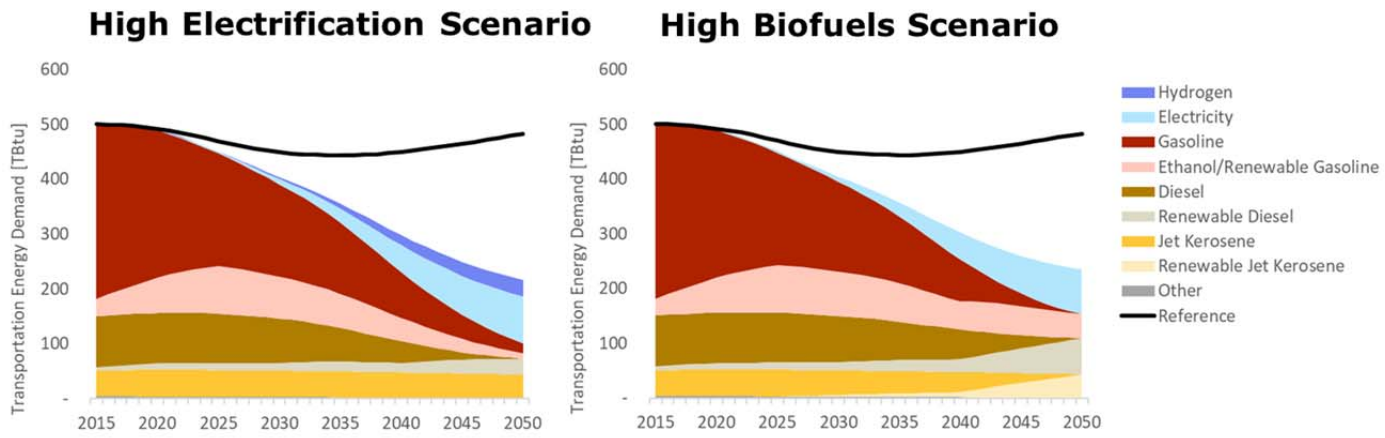

Figure 17. Total energy consumption by fuel and scenario in transportation

3.2.3 ELECTRICITY GENERATION

Each mitigation scenario has very different assumptions about adoption of electric technologies and therefore different projections of electricity demand, as shown in Figure 18. The High Electrification Scenario includes high adoption of electric household appliances, electric vehicles, and electrolysis to produce hydrogen for heavy-duty vehicles. The High Biofuels Scenario includes adoption of electric vehicles in light and medium duty vehicles, but lower electrification in other sectors. This leads to a load increase of 60% relative to 2015 in the High Electrification Scenario, and a much smaller load increase in the High Biofuels Scenario.

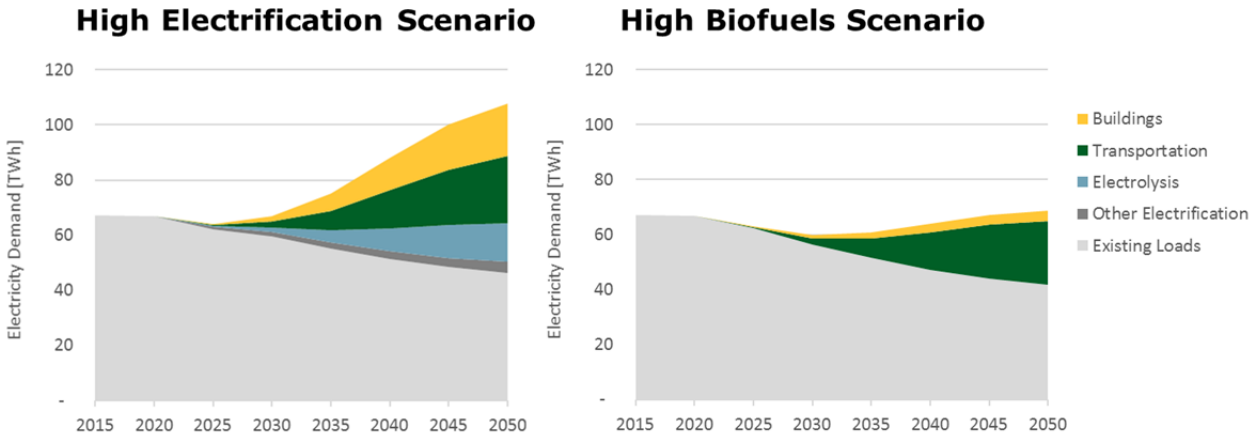

Figure 18. Electricity demand by sector and mitigation scenario

Demands for electricity determine required electricity generation. Each mitigation scenario achieves a 90% share of carbon-free electricity by 2050, but serves very different electricity demand, as shown in Figure 19.

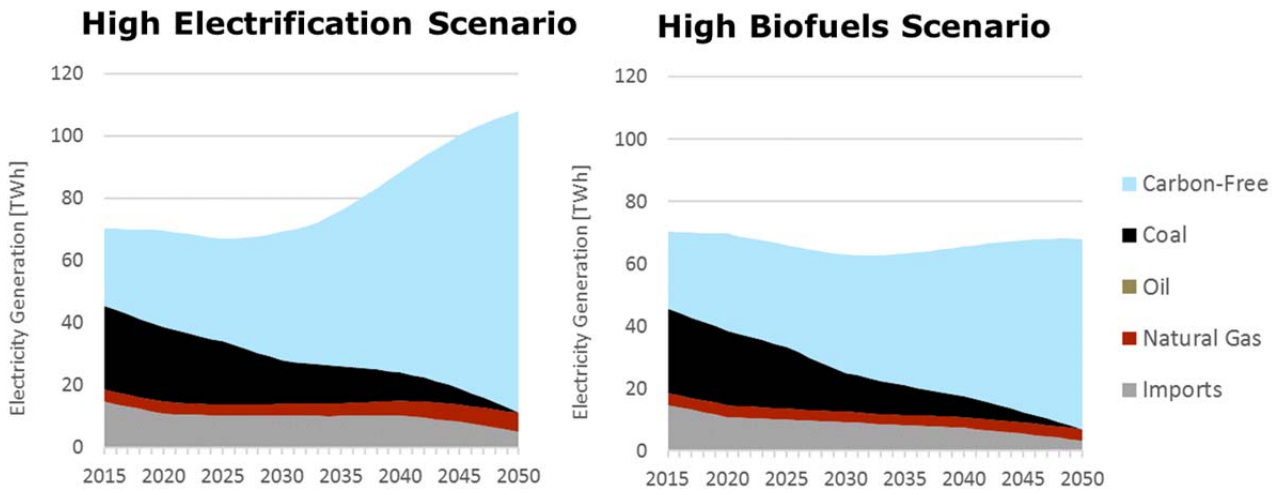

Figure 19. Total electricity generation by sources and mitigation scenario

Our accounting of GHG emissions aligns with the approach taken in the PCA's GHG Inventory, which accounts for all emissions from production of electricity in the electricity generation sector. In our scenarios, this shows a significant reduction in direct GHG reductions due to transitioning to carbon-free resources in our mitigation scenarios (see solid blue bars in Figure 20). In addition to those emission reductions, additional emissions are avoided in buildings and transportation, where electrification avoids emissions from direct combustion of natural gas, gasoline, and diesel fuels. Both Mitigation Scenarios reach 90% carbon-free electricity in 2050, but since the High Electrification scenario serves about 60% higher loads, total emissions in that scenario are 2 Million Short Tons higher, as shown in Table 17Table 18. Also shown are enabled emissions reductions in buildings and transportation in negative hatched bars, representing the petroleum and natural gas emissions avoided by switching to electric vehicles and appliances. Both Mitigation Scenarios see additional emission reductions due to electrification in buildings and transportation. The High Electrification scenario has increased direct electricity emissions of serving higher loads, but avoids an additional 20 MST CO2e elsewhere in the economy through electrification compared to the High Biofuels scenario

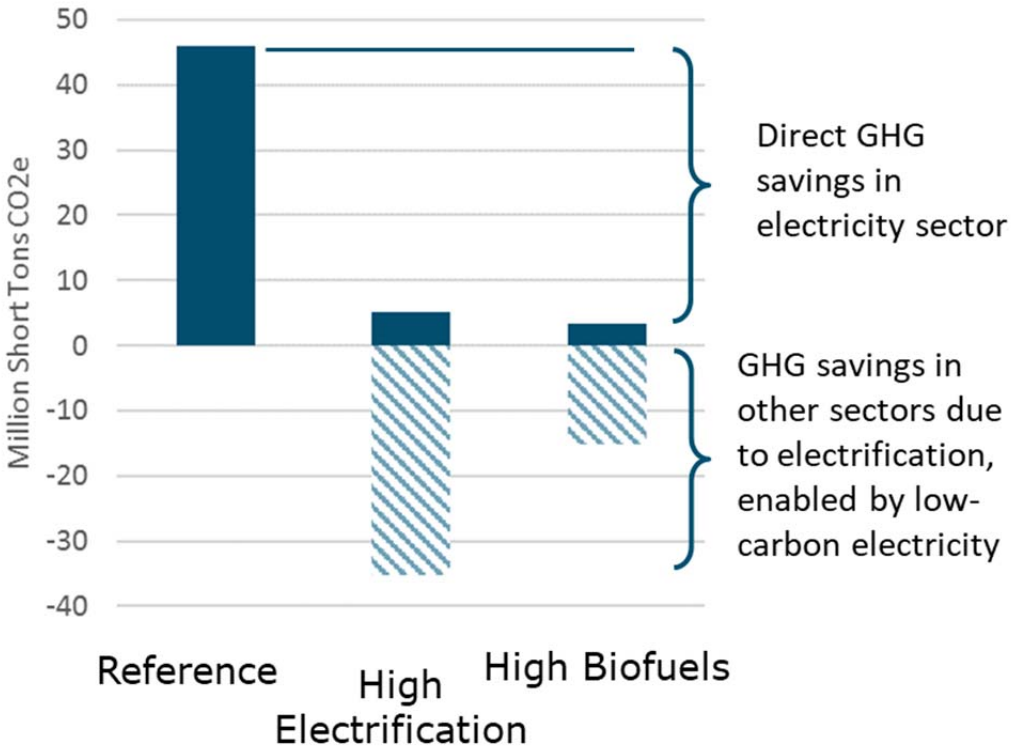

Figure 20. Electric sector GHG emissions by scenario in 2050

Table 17. Electric sector direct GHG emissions and indirect GHG reductions in 2050 [MST CO2e]

	Reference Scenario	High Electrification Scenario	High Biofuels Scenario
Total Direct Emissions from Electricity Generation	46	5	3
Total Emission Reductions from Other Sectors by Switching to Electric Devices		-35	-15

3.2.4 SENSITIVITY ANALYSIS

In addition to mitigation scenarios, we developed three sensitivities to test the impact on emissions of federal action and consumer adoption. The three sensitivities were defined as follows:

1. **Sensitivity #1: Efficiency, Electrification, and Clean Electricity Only**: Evaluates the impact of only pursuing building efficiency, high adoption of electric vehicles and household devices, and clean electricity towards meeting GHG targets
2. **Sensitivity #2: No CAFE Extension**: Evaluates the impact of freezing federal Corporate Average Fuel Economy (CAFE) standards from at 2020 levels.

3. **Sensitivity #3: Lower Electric Adoption**: Evaluates the combined impact of lower consumer adoption of electric vehicles and electric household devices.

3.2.4.1 Sensitivity #1: Efficiency, Electrification, and Clean Electricity

The first sensitivity we tested was a mitigation scenario that focused first on the emissions benefits of pursuing aggressive efficiency and electrification with higher shares of carbon-free electricity. This sensitivity is different from the High Electrification Scenario, which includes measures in other sectors such as industry, agriculture, and waste that allow the scenario to meet economy-wide goals

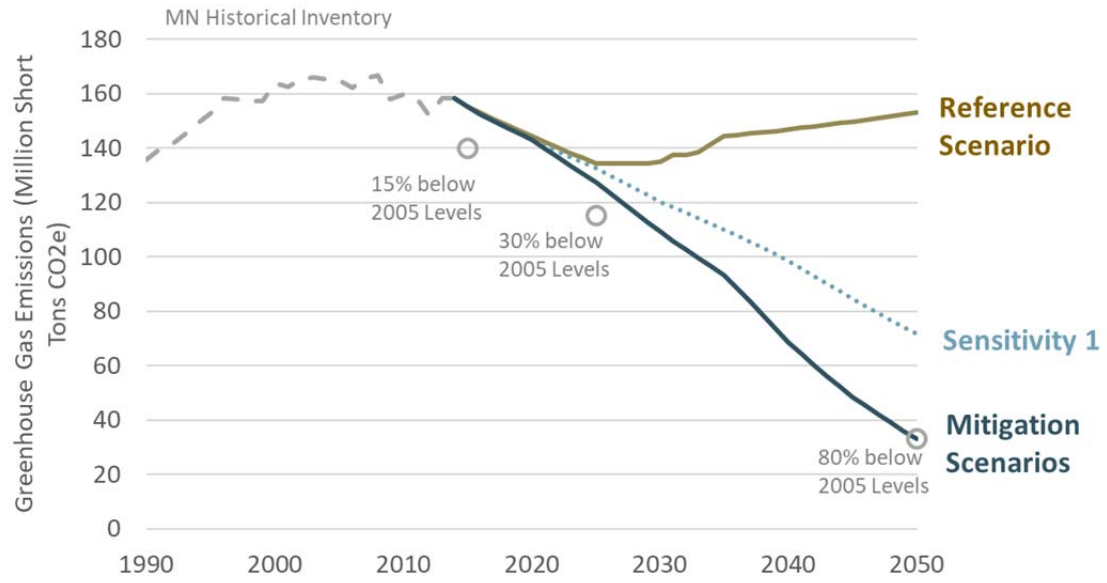

Figure 21. GHG Emissions from Sensitivity 1 relative to Reference and Mitigation Scenarios

This scenario highlights the need for additional measures and actions to meet the economy-wide GHG goal.

3.2.4.2 Sensitivity #2: No CAFE Extension

Federal Corporate Average Fuel Economy (CAFE) Standards impact the on-road efficiency of new light-duty vehicles sold in the US. The current federal administration has proposed freezing the standards at 2020 levels, removing the extension of the program from 2021 to 2026. We ran a sensitivity on our Reference Scenario and High Electrification Scenarios to quantify the impact of removing this federal program.

All scenarios benefit from CAFE improvements through 2020, but the sensitivity assumes no incremental improvement in new vehicles sold starting in 2021.

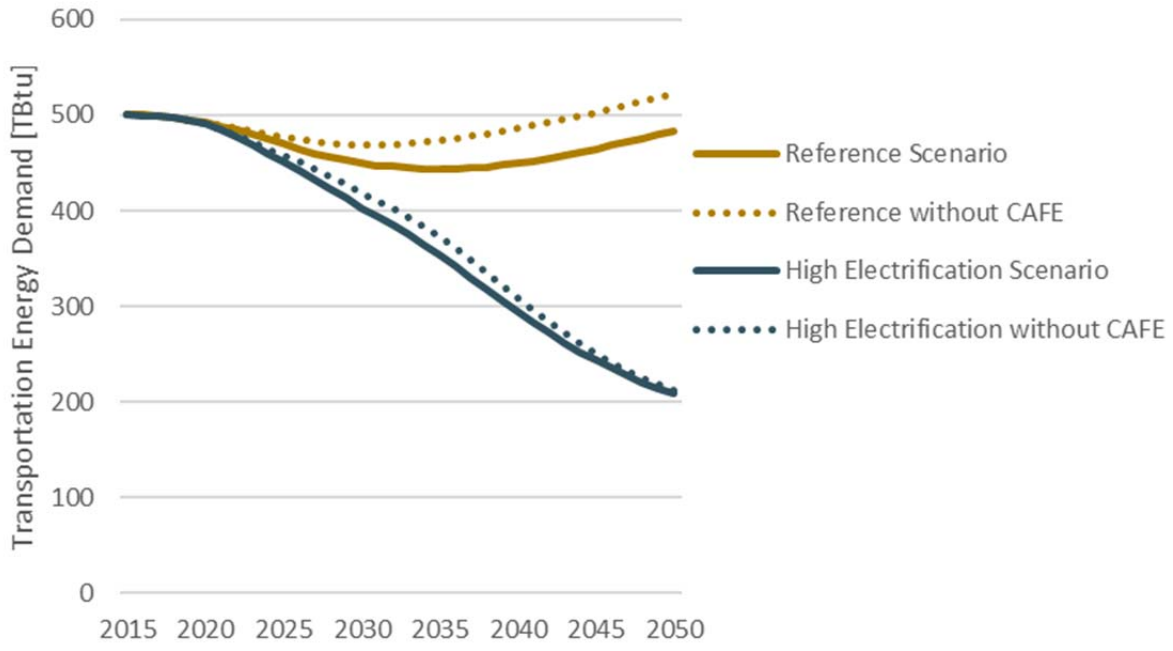

Figure 22. Total energy consumption in transportation by scenario and sensitivity

As shown in Figure 22, federal fuel economy standards have a larger impact on the Reference Scenario, which assumes more internal combustion engine vehicles are sold. Impacts are smaller in the High Electrification Scenario, especially by 2050, due to increasing share of electric vehicles on the road.

Emissions impacts are small relative to economy-wide emissions (see Figure 23). Incremental emissions are 1.5 MST CO2e in 2050 in the Reference Scenario and 0.1 MST CO2e in the High Electrification Scenario.

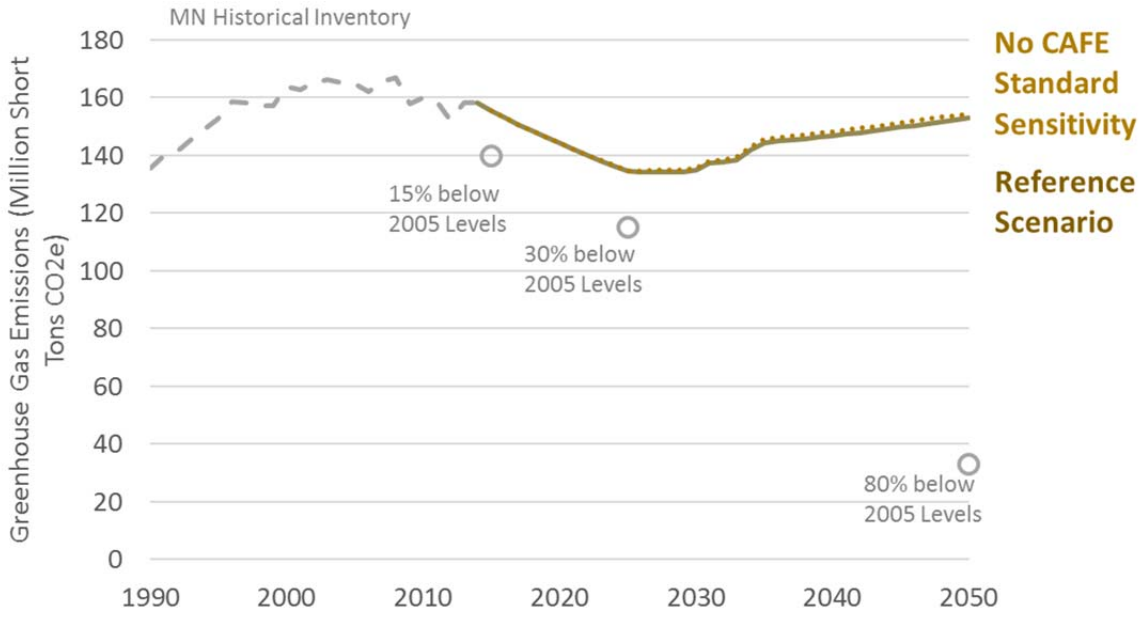

Figure 23. Total Minnesota GHG Emissions in the Reference Scenario and No CAFE Standard Extension Sensitivity

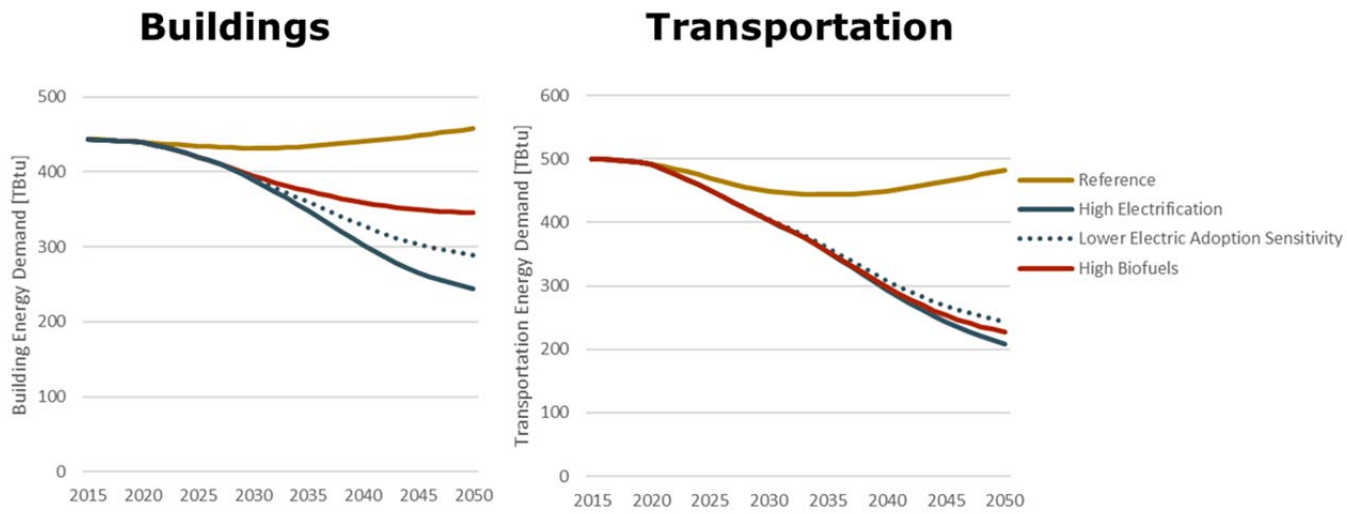
3.2.4.3 Sensitivity #3: Lower Electric Adoption

Rates of consumer adoption for new electric vehicles and electric appliances are uncertain. Our High Electrification Scenario assumes that no internal combustion engine vehicles or natural gas furnaces are sold by 2050. This sensitivity tests a lower level of adoption of key electric technologies, aligning with assumptions from NREL's Electrification Futures Study.[12] Full assumptions are shown in Table 18.

Table 18. New sales assumptions for key electric technologies in Mitigation Scenarios and Sensitivity #3 [% of new sales]

	High Electrification Scenario	High Biofuels Scenario	Lower Electric Adoption Sensitivity
Medium Duty ZEVs	100%	80%	60%
Heavy Duty ZEVs	100%	50%	40%
Heat Pumps in Residential Space Heating	100%	22%	80%
Heat Pumps in Residential Water Heating	100%	33%	30%
Heat Pumps in Commercial Space Heating	98%	2%	60%
Heat Pumps in Commercial Water Heating	100%	8%	30%

Impacts on energy consumption of the Lower Electric Adoption Sensitivity are shown by sector in Figure 24. The largest impacts are seen in buildings, representing the NREL assumption of lower adoption of heat pump water heaters and commercial space heaters than assumed in the High Electrification Scenario.



[12] Report available online: https://www.nrel.gov/docs/fy18osti/71500.pdf

Figure 24. Total energy consumption in buildings and transportation by scenario and sensitivity

Figure 25 shows the emissions gap of 7.9 MST CO2e in 2050 created by lower levels of adoption relative to the High Electrification Scenario. If adoption is lower than expected in the High Electrification Scenario, emissions in Minnesota will fall short of the 2050 NGEA goal and additional measures would need to compensate.

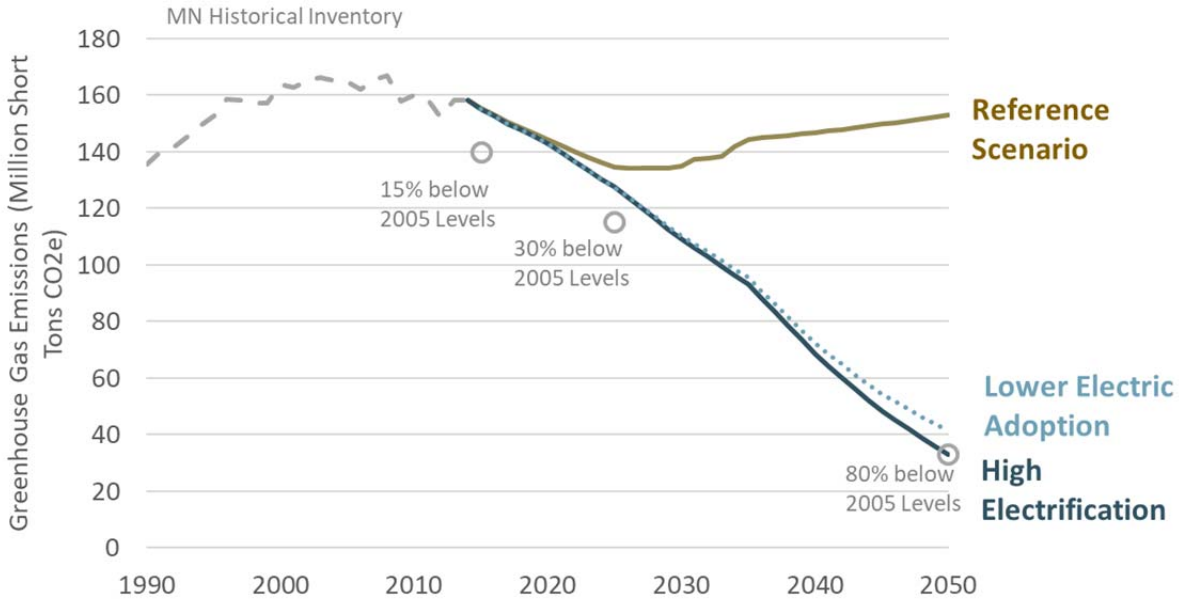


Figure 25. Total Minnesota GHG emissions in Lower Electric Adoption Sensitivity

3.3 Key Findings

The goal of this analysis was to develop a set of long-term economy-wide scenarios that reach the Next Generation Energy Act GHG emission targets for Minnesota of 80% reductions by 2050 relative to 2005 levels. These scenarios provide an exploration of the cross-sectoral implications of meeting economy-wide carbon reduction goals and highlight the role of the electric sector in meeting the state's economy-wide carbon goal. Based on the detailed analysis of Minnesota's statewide energy and emissions, we find the following:

Significant action is needed in every sector to decarbonize the state of Minnesota. This analysis highlights the need for aggressive action across all sectors of Minnesota's economy to meet a statewide goal of 80% reduction below 2005 levels. Reaching the NGEA goal of 80% GHG reductions by 2050 is challenging and will require significant effort beyond current policies within the state.

Buildings and transportation have significant potential to drive load growth, especially after 2025. The High Electrification Scenario highlights the significant potential for adoption of new electric appliances and vehicles, and the potential impact on total electricity requirements for Minnesota utilities. Transportation and building electrification drive electric load growth, especially after 2030, particularly in a future with less biofuels. Electrification of space heating has a particularly large impact on both total load (MWh) and peak demand (MW).

Reasonable electric rates and low costs for new electric devices are essential for electrification. The levels of electrification modeled in buildings and transportation are dependent on consumer adoption, which will benefit from reductions in capital costs and reasonable electric rates, even as the electric grid continues to decarbonize.

Electrification and zero-carbon electricity are necessary but not enough to reach statewide goals. Each Mitigation Scenario shows that increased reliance on low-carbon electricity enables emission reductions by avoiding direct combustion of fossil fuels in households, businesses, and vehicles. We also show that electrification and carbon-free electricity are necessary building blocks of a Mitigation Scenario but are not sufficient without additional measures and actions within the state.

This work highlights areas of future research. The scenarios modeled in this analysis represent an initial modeling assessment of required emission reductions in the state. This analysis has focused on emissions in electricity generation, buildings, and transportation, but further research is needed to explore building electrification impacts in Minnesota's climate and next steps for policy implementation within the state. In other sectors, further research is needed around opportunities in biofuels, agriculture, waste, and industrial sectors.

SECTION 1 INTRODUCTION

As part of the 2015 NSP Integrated Resource Plan, the Company was ordered to obtain a wind integration study. The objective of this study was to estimate the costs of integrating wind generation onto the Company system. These costs are associated with the uncertain and variable nature of wind generation and represent additional costs required to maintain overall system operations and reliability. Results from the study were used in the resource planning and selection process to ensure that wind generation resources continue to be compared on a level playing field with other technologies.

For the upcoming 2019 IRP filing, the Company employed EnerNex to perform another study to examine the impact of wind and solar integration on the NSP system as well. This study analyzed the integration costs under different levels of renewable penetration in three different time periods to assess the impact of major coal retirements and other key changes. EnerNex contracted with Leidos Engineering to perform the PROMOD analysis.

SECTION 2 STUDY ASSUMPTOINS

The following list of study assumptions were made in the study.

Data used in the study is based upon the Continued Fleet Change scenario from MISO MTEP18 database. It was agreed that the use of this database would best represent the NSP system for this study.

The NSP resources are located within the LRZ1 zone of MISO and were identified by Xcel – NSP. LRZ1 has other resources and load serving resources that do not belong to Xcel – NSP however have transmission ties to NSP.

Reserves modeled for all MISO in MTEP18 are 1957 MW. NSP reserves are Operating: 27 MW, Spin: 65 MW, and Supplemental: 71 MW.

Incremental wind and solar included in MTEP 18 forecast will not count as part of NSP incremental wind and solar. The assumption being that the MISO increments consider other 3rd party additions to LRZ1. The incremental wind in this study is specific to the NSP system.

The 62MW Marshal Solar Project is added to MTEP18 database.

The 25 MW MN Solar 1 project is removed from the MTEP18 database.

The Fibrowatt Benson: 1 biomass resource is removed from the MTEP18 database. The facility is shutting down.

The Virginia: ST biomass resource is removed from the MTEP18 database. The facility is shutting down.

The Hibbing: ST biomass resource is removed from the MTEP18 database. The facility is shutting down.

Scenario 1: Year 2022 add incremental NSP wind of 1500 MW, 1000 MW solar, 400 MW DR, add BD6

Scenario 2: Year 2027 builds on Scenario 1 adding incremental NSP wind of 1000 MW, 1000 MW solar, and Sherco CC; retire Sherco 1 & 2

Scenario 3: Year 2032 builds on Scenario 2 adding incremental NSP wind of 500 MW, 1000 MW solar, retire King

Scenario 4: Year 2032 also builds on Scenario 2 adding incremental NSP wind of 1500 MW (500 MW from Scenario 3 plus additional 1000 MW), 3000 MW solar (1000 MW from Scenario 3 plus additional 2000 MW), and Retire all Nuclear. The cases studied are shown in Table 1.

EnerNex
A CESI Company

Table 1: Scenarios Studied

Scenario	Year	Wind	Solar	Other Changes
Base	2022	-	-	-
1	2022	+1,500 MW	+1,000 MW	Add 400 MW DR, Add Black Dog 6
2	2027	Scenario 1 +1,000 MW	Scenario 1 +1,000 MW	Retire Sherco 1&2, Add Sherco CC
3	2032	Scenario 2 +500 MW	Scenario 2 +1,000 MW	Retire King
4	2032	Scenario 2 +1,500 MW	Scenario 2 +3,000 MW	Retire All Nuclear

The additional incremental wind and solar resources will be modeled by selecting profiles from the MTEP18 database that are NSP resources in LRZ1. To help minimize congestion each incremental resource will be assigned to an NSP bus capable of handling the increased generation. There are 38 wind profiles and 17 solar profiles in the MTEP18 database from which to select incremental wind and solar profiles. These profiles will be scaled to meet the required capacity for the incremental wind and solar in each scenario.

The MTEP18 database uses wind profiles obtained from the NREL Wind database year 2012. MISO provided the site ID's associated with most of the existing NSP wind plants. Site ID's not identified by MISO were assigned NREL Site ID's by selecting a site close to the PSS/E bus location, shaded ID's in Table 2.

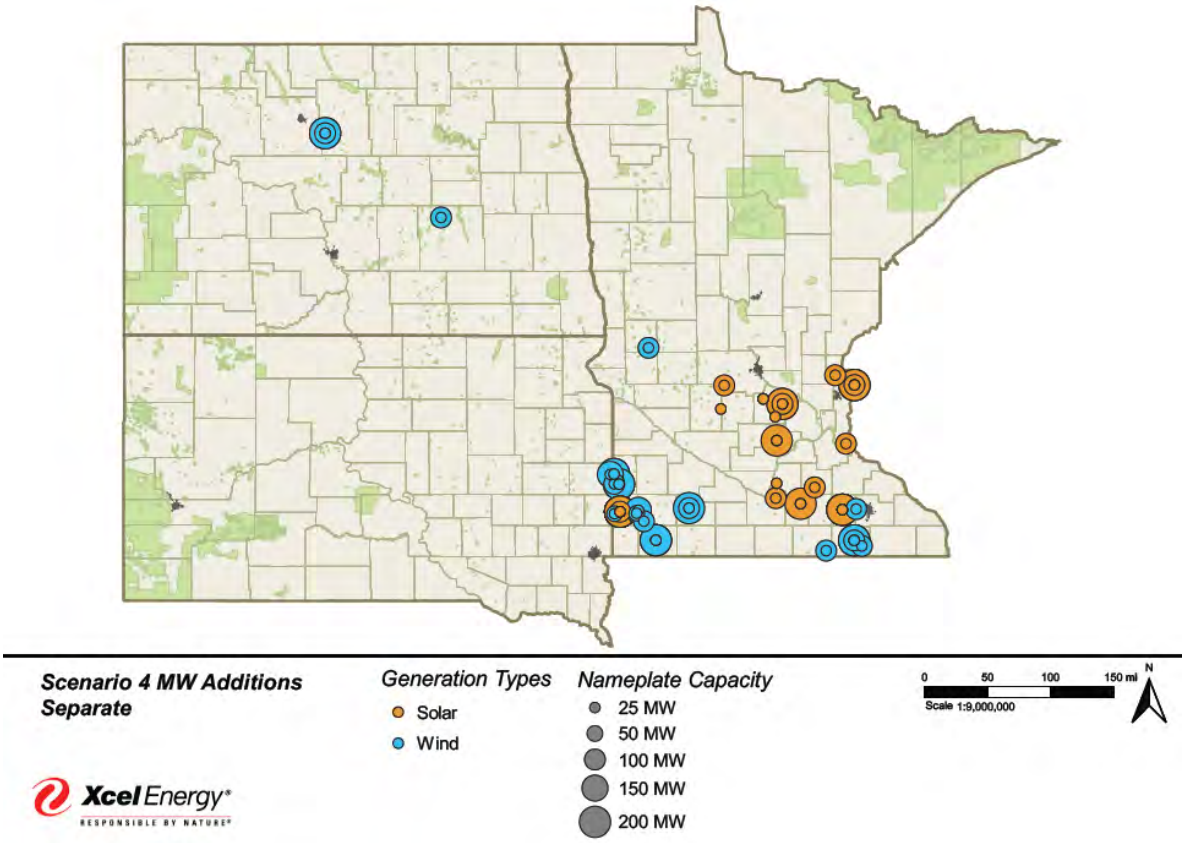

Figure 4: Scenario 4 Wind and Solar PV Site Map

Day ahead forecasts for incremental wind were obtained directly from the NREL Wind database.

Day ahead forecasts for solar and Load were calculated by NSP using a statistical approach using as a basis the actual and forecast data for solar and Load. For solar Northstar and Marshal Plant data from the most recent 12 months were used assuming this would mimic the current level of forecast accuracy. Whenever actual generation profile = 0 MW the forecast for that hour would also be 0 MW. Solar production included generation plus curtailed energy was separated into deciles of 0% -10%, 10% - 20%, etc. A Forecast % adder calculated by taking the difference between Forecast and Gen and dividing by the capacity of solar plant. The associated forecast % is calculated by summing Generation % by capacity of solar facility. The Northstar decile patterns were used to develop forecasts for 100MW facilities. The Marshal Plant decile patterns were used to develop forecasts for 25 MW facilities. Forecast profiles were not allowed to be less than zero or larger than 100% capacity. This method produced Forecast profiles with slightly higher capacity factor than generation profile (over forecast). In the most recent 12 month period both Northstar and Marshal Forecasts had higher capacity factor than Actual generation. The MAPE for the aggregate solar Forecast is better than that for all individual solar plants. This is expected due to geographic diversity of the various solar plants.

SECTION 3 METHODOLOGY

The NSP system is a dispatched by the MISO. Therefore the evaluation of the impact of wind and solar PV on the NSP system requires modeling the MISO and extracting the dispatch costs for the NSP resources. The MISO employs the PROMOD tool in evaluation of its system and developed the MTEP18 database as a model representing the operating companies under its jurisdiction. This study used the MTEP18 database and PROMOD tool in modeling the increase in wind and solar PV penetration on the NSP system. Leidos Engineering performed the PROMOD analysis.

Four scenarios were modeled as described in the assumptions section above. Each scenario applied additional wind and solar PV to the NSP system in addition to the base wind and solar modeled in the MTEP18 database.

Two PROMOD runs were performed for each scenario. The first is a "No error" run (NE) that models a perfect knowledge of actual production for NSP wind and solar resources, with no forecast error assumed. The final production energy profiles for NSP wind and solar generation were used in both the unit commitment decision (similar to Day-ahead market decision) and dispatch optimization (similar to Real-time market). This run also assumes perfect knowledge of the actual NSP load in both commitment and dispatch steps. This run provides the optimal operating dispatch for the NSP resources.

The second PROMOD run is a "Forecast Error" run (FE) that takes into account the day-ahead forecast for wind, solar PV and NSP load. This run performs the unit commitment of the NSP resources based upon the wind, solar PV and NSP load day-ahead forecasts and then performs the dispatch optimization of all resources based upon the actual wind, solar PV and NSP load. The result of this run is different from the first run in that it incorporates the cost of uncertainty due to the wind, solar PV and load forecast errors. For example an over forecast of wind and Solar PV can result in an under commitment of other resources, assuming the load forecast is the same as the actual. An hourly chronological program like PROMOD allows for various combinations of over and under forecasts of wind, solar PV and load throughout the studied year.

The results from the No Error (NE) and Forecast Error runs (FE) are compared for different analysis that will be described later in the report. These include spinning reserve, resource cycling, fuel burn and integration cost due to forecast error.

The data required for modeling wind and solar PV resources in the NSP system was collected with the support of NSP. Wind production and day ahead forecasts were extracted from the NREL wind database using base year 2012. This is consistent with the wind data modeled in the MTEP18 database. Solar production data and the NSP load data were extracted by PROMOD from the MTEP18 database for study year 2022. The Solar and NSP load day ahead forecast were derived statistically from existing solar and NSP load day ahead forecast and actual data. The wind, solar PV and load data were analyzed with results shown in separate presentation.

In order to insure the additional wind and solar PV energy can be integrated into the NSP system a preliminary analysis using proxy wind and solar profiles were used and modeled in PROMOD. Each scenario was set up with the specified generator retirements and incremental renewable generation at transmission buses as designated by NSP. Congestion was measured by flow-gate shadow price ($/MWh), the marginal cost of system dispatch to mitigate congestion. Over 600 flow gates in MTEP 18

were assessed to identify flow gates that become very congested to incremental NSP Renewables. Severe congestion on the Adams 161/69 transformer Adams – Beaver Crk 161 flow-gate was identified in the preliminary analysis of PROMOD runs.. It was then noted that the MTEP18 database being used was lacking an update from the MISO for this transmission line. The upgrade was provided by MISO and implemented in the database for the study.

A CESI Company

SECTION 4 RENEWABLE CHARACTERIZATION

This section provides an analysis of the wind and solar PV modeled in this study. The annual wind and solar PV annual production for each scenario is shown in Figure 5. The total base renewable energy in 2022 is 11.5 TWH of which 11.1 TWH is wind. Scenario 2 models year 2027 builds off of Scenario 1 with total annual renewable energy of 19.5 TWH with wind contributing 17.1 TWH. Scenario 3 and Scenario 4 models year 2032 and are build off of Scenario 2. Scenario 3 has total annual renewable energy of 29.2 TWH of which wind contributes 23 TWH and Scenario 4 has total annual renewable energy of 37.1 TWH of which 27 TWH consists of wind.

	Base	S1 Inc	S1 Total	S2 Inc	S2 Total	S3 Inc	S3 Total	S4 Inc	S4 Total
Wind	11.1	6.1	17.1	4.0	21.1	1.9	23.0	5.9	27.0
PV	0.5	1.9	2.3	2.0	4.3	1.9	6.2	5.7	10.0
Total	11.5	7.9	19.5	5.9	25.4	3.8	29.2	11.7	37.1

Figure 5: Scenario Renewable Annual Energy Summary

The capacity factors for the aggregated wind and solar PV resources in the study are shown in Figure 6. The Capacity factors for wind in each scenario are in the 46% range with the Base, Scenrio1, Scenario 2, Scenario 3 and Scenario 4 having capacity factors of 46.4%, 46.3%, 46.1%, 45.9% and 45.1% respectively. Solar PV aggregated annual capacity factors for the Base, Scenario1, Scenario 2, Scenario 3 and Scenario 4 are 20.1%, 20.9%, 21.6%, 21.6% and 21.9%.

	Base	S1 Inc	S1 Total	S2 Inc	S2 Total	S3 Inc	S3 Total	S4 Inc	S4 Total
Wind	46.4%	46.2%	46.3%	45.1%	46.1%	43.5%	45.9%	45.1%	45.9%
PV	20.1%	21.1%	20.9%	22.5%	21.6%	21.5%	21.6%	21.9%	21.8%
Total	44.2%	36.2%	40.6%	33.9%	38.8%	28.8%	37.0%	29.6%	35.2%

Figure 6: Scenario Renewable Annual Capacity Factor

Examining the quarterly renewable energy production, wind energy production is greatest in the January through March months with July through September being the lowest production time in the year. The Wind energy production in the April through June and October through December months are approximately the same Figure 7.

Figure 10: Quarterly Scenario Aggregated Solar PV Capacity Factor

Wind variability was quantified in this study by examining the change in aggregated wind production from one hour to the next. An up – ramp is defined when the present hour is greater than the previous hour and a down – ramp is defined when the present hour is less than the previous hour. This analysis evaluated the hour to hour aggregated changes in wind production over the study year for each scenario. As expected the maximum up and down ramps increase as the penetration of wind increases. The maximum up – ramp range is 879 MW for the Base to 2087 MW hour to hour change in Scenario 4. Similarly calculated the maximum down – ramp range is 1132 MW for the Base to 2770 MW in Scenario 4. Figure 11 shows the plot of the hour to hour changes over the year sorted from high to low. A Histogram shows the up – ramps and down – ramps in Figure 12. Table 3 shows the top 5 up and down ramps for each scenario. Table 4 shows the percent of hours when up – ramps and down – ramps exceed 5% and 10% of the wind rated capacity.

Solar PV variability was quantified in this study in a similar way as wind by examining the change in aggregated Solar PV production from one hour to the next. This study evaluated the hour to hour aggregated changes in solar PV production over the study year for each scenario. As expected the maximum up and down ramps increase as the penetration of solar PV increases. The maximum up – ramp range is 94 MW for the Base to 2252 MW hour to hour change in Scenario 4. Similarly calculated the maximum down – ramp range is 93 MW for the Base to 2351 MW in Scenario 4. Figure 13 shows the plot of the hour to hour changes over the year sorted from high to low. Table 3 shows the top 5 up and down ramps for each scenario. A Histogram shows the up – ramps and down – ramps in Figure 14. Table 5 shows the top 5 up and down ramps for each scenario. Table 6 shows the percent of hours when up – ramps and down – ramps exceed 5% and 10% of the solar PV rated capacity.

SECTION 5 NSP SYSTEM LOAD

NSP system load for the study years was extracted from the MTEP18 database. Peak load in 2022 is 9686 MW and escalated to 9833 MW in 2027 and again to 9982 MW in 2032. Minimum load in each study year of 2022, 2027 and 2032 is 3482 MW, 3524 MW and 3577 MW respectively. The quarterly NSP system peak and minimum load for each scenario is shown in Figure 15. The annual NSP load demand in TWH in 2022 is 46, 69 TWH, in 2027 load demand is 47.28 TWH and in 2032 load demand is 47.89 TWH as shown in Figure 16. The NSP load factor is shown in Figure 17.

Figure 17: NSP Load Factor by Quarter

The NSP load variability, change from hour to hour, was examined in a similar way as the variable wind and solar PV resources. The changes in NSP system load from hour to hour was evaluated and ranked from largest hourly change to smallest Figure 18. In addition the hourly changes were evaluated in a histogram placing the hourly changes into bins representing 25 MW bins, Figure 19. Table 7 shows the five largest and smallest changes in hourly load.

SECTION 6 NET LOAD

Net load in this section is defined to be the result of subtracting in each hour of the study the amount of wind and solar PV from the NSP system load. This analysis provides further insight into the effects of wind and solar PV on the NSP system making the assumption that the energy produced by wind and solar PV are must take resource and applied to serving system load or off system sale. Table 8 shows for the Base and each Scenario the annual load MWH, Net Load MWH, Renewable MWH, Wind MWH, Solar PV MWH, % of renewable penetration, % of wind penetration, % of solar PV penetration, number of days in the year when renewable energy is greater than load demand, and the number of weeks in the year when renewable energy is greater than load demand. The annual MWH for net load from Scenario 1 to Scenario 4 is reduced by 61%. In Scenario 2 through Scenario 4 there are days when the renewable production exceeds load demand. Additionally in Scenario 4 there are six weeks in the year when renewable production exceeds the weekly NSP demand. Remedial action of curtailment or selling the additional energy can provide mitigation of this excess production.

Table 8: Net Load Characterization for each Scenario

Annual	Base	S1	S2	S3	S4
Load MWH	46,689,259	46,689,259	47,284,693	47,887,784	47,887,784
Net Load MWH	35,879,431	27,300,971	22,008,297	18,637,437	10,736,553
Ren MWH	10,809,828	19,388,288	25,276,396	29,250,347	37,151,231
Wind MWH	10,345,983	17,073,715	20,987,190	23,070,216	27,107,553
PV MWH	463,845	2,314,573	4,289,206	6,180,131	10,043,679
Renewable Penetration % of MWH	23%	42%	53%	61%	78%
Wind Penetration % of MWH	22%	37%	44%	48%	57%
Solar PV Penetration % of MWH	1%	5%	9%	13%	21%
# days Renewable MWH > Load MWH	0	0	19	37	99
# Weeks Renewable MWH > Load MWH	0	0	0	0	6

Net load analysis provided the ability to compare the previously described load analysis to net load. Figure 21 shows the peak and min load and net load by quarter and year. Here it can be seen that renewable configurations in this analysis have a greater effect on minimum load than on the peak load. Another way of observing net load is by examining a histogram counting the number of hour in the year when load or net load falls with a given MW range. The histogram shown in Figure 20 uses the peak load in 2032 and the minimum load in Scenario 4 as boundaries and places in bins sized to 1% of this range. It can be seen in this figure how the NSP net load is modified by the increase in renewable wind and Solar PV.

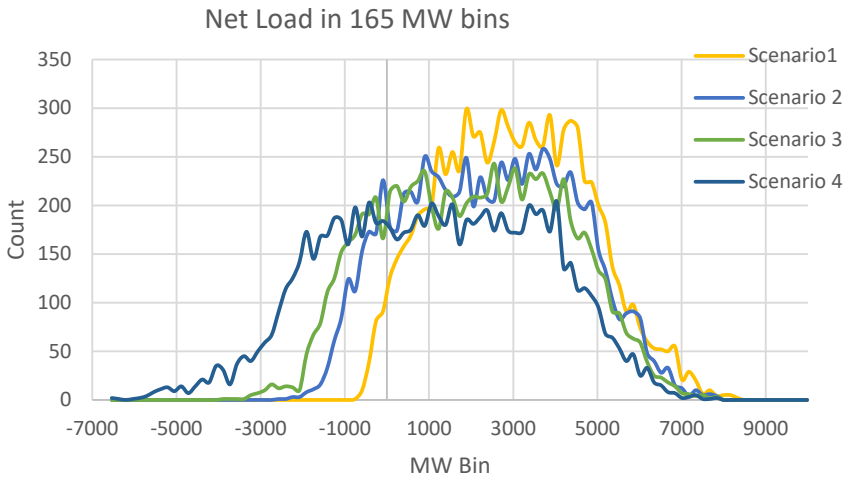

Figure 20: Histogram of Net Load for each study year and Scenario

The analysis of hour to hour net load changes was performed in the same way as load in that the hourly changes were ordered from high to low and plotted in Figure 22, Figure 23, Figure 24 and Figure 25. The hourly load change is plotted to show the differences between the hourly changes in load verses net load. These plots show the number of hour in the year when net load is less than 0 MW, from 179 hours in Scenario 1 to 2988 hours in Scenario 4.

The magnitude and number of hour to hour changes in net load increase in each scenario as penetration increases. This is shown in Figure 26, Figure 27 and Figure 28. The histogram for net load is shown in

The load and net load analysis provided additional insights into the hour to hour behavior when wind and solar PV is introduced. Plots of individual days and weeks are shown in the final presentation. The tables depicting the days and weeks of interest are shown in the four tables, Table 9, Table 10, Table 11 and Table 12

An example of an interesting day and week is the week with the day April 10. April 10 has a high wind and solar PV production while the load on this day is relatively low. In each scenario as penetration increases the net load decreases. For the day the Base Load is 93,793 MWH the Base net load is 10,642 MW. Scenario 1 net load is 14,642 MWH. Scenario 2 is -28,596 MWH, Scenario 3 is -47,378 MWH, and Scenario 4 is -84,711 MWH. Figure 30, Figure 31, Figure 32, Figure 33 and Figure 34 show the effects of the renewable penetration on the NSP load. In the Base the net load is within the 1000 MW to 2000 MW range while as renewable penetration increases in each scenario there are hours when net load for NSP becomes negative in Scenario 1 and for the full day in Scenario 2, Scenario 3 and Scenario 4.

SECTION 7 RESERVE

As described in the previous section Net Load shows there is an increase in the hour to hour load change as the penetration of renewables increases. Spinning reserves are typically established to account for these load variations that occur within the hour. Therefore, as the tendency for hour to hour load change increase with renewable penetration, the spinning reserves will also change. The changes in spinning reserves in this study were calculated statistically using the method applied in numerous other studies[1, 2, 3]. The Base Case set NSP Base Reserves at 27 MW, Spin at 65 MW and Supplement at 71 MW. The forecasts used in this analysis were persistence (next hour forecast is the same as present hour) for load and wind. The forecast for solar PV used the average three production values, the hour of, the hour before and the hour after. These forecasts provided a forecast error for the next hour forecast. Associating the forecast error to the level of wind and solar PV production the production levels for these renewable types were placed into histogram bins at 10% production intervals. From each of these bins the standard deviation of the forecast error was calculated and plotted against the production level. A curve fit of the plot results in a quadratic curve. From this curve the statistical standard deviation of the forecast error for wind and solar PV can be calculated. In addition statistically three standard deviations, or three times the calculated standard deviation of forecast error covers 99.7% of the possible forecast errors for wind or solar PV.

Because the Base Case includes renewables, the spinning reserve contribution to renewables was calculated and included in the spinning reserve analysis for each Scenario. The formula for calculating the 10 – minute spinning reserve is based on predictive operating levels of load, wind and solar PV forecast errors and is shown below.

$$3 * \sqrt{(\frac{\%Hourly\ Load}{3})^2 + \sigma(HourlyWind)^2 + \sigma(HourlySolarPV)^2}$$ = 65 MW for the Base Case

The calculated 10-minute spinning reserve changes demonstrate that as renewable penetration increases the average 10-minute spinning reserve requirement also increases. In general the analysis shows the contribution of 10-minute spinning reserves in this study ranges between 0.7% and 0.9% of the renewable rated capacity. Table 13 provides the calculated 10-minute spinning reserve requirements. The spinning reserve contribution of renewables increases from 25 MW in Scenario 1 to 76 MW in Scenario 4 more than doubling the reserve requirement in the Base Case.

Table 13: 10 – Minute Spinning Reserves for each Scenario

Average Contribution 10-min Spin Reserve (MW)			
Scenario	Load	Renewable	Total
Base	43	22	65
S1	43	47	90
S2	43	62	105
S3	43	73	116
S4	43	98	141

In order to verify these calculations a post analysis of the PROMOD runs was performed to determine if these levels of reserves were sufficient. The loading of NSP resources for each hour in the study were examined. The Headroom for each on line resource was calculated by subtracting the resource loading in the hour from its available capacity. This value was limited by the respective resource ramping rate. The headroom for all resources was aggregated by hour to provide the total available on line spinning generation. The number of hours in the year when the calculated 10 – minute spinning reserve was exceeded was determined. Table 14 depicts the results of the post analysis. The number of hours in the year when the calculated spinning reserve exceeds the NSP resource headroom, the percent of hours in the year when spinning reserve exceeds the NSP resource headroom, the maximum MW of NSP resources that exceeds the spinning reserve requirement and the hour of maximum deficiency for spinning reserves are shown. The worst case is in Scenario 4 when there is an hour when the NSP system is deficient of 145 MW of spinning reserves. In these hours the NSP system would rely on the MISO for mitigation.

SECTION 8 RESULTS

This section provides the PROMOD production costs for the Base Case and Each Scenario. The MTEP 18 PROMOD model includes all RTOs, ISOs, and balancing areas in the Eastern Interconnect. The results extracted from the runs were focused strictly on the NSP system.

There were two sets of PROMOD runs performed in this analysis. The first type (NE) modeled the NSP system without any renewable and load forecast error. This run performed both unit commitment and dispatch steps using the actual values for the hourly wind and solar PV energy and the NSP load. The second type of run (FE) performed the unit commitment using a day-ahead forecast for hourly wind and solar PV energy and NSP load, and then solved the unit dispatch optimization based upon actual values for hourly wind and solar PV energy and NSP load. This second run will have a different production cost than the first due to the forecast used in the commitment stage. An over forecast of wind or solar PV can result in an under commitment of system resources, as would an under forecast of system load. Similarly an under forecast of wind or solar PV would result in an over commitment of system resources. As would an over forecast of system load. Sometimes the over forecast of wind and solar PV is compensated by an under forecast of system load. The hourly chronological production costing model evaluates these combinations of over and under forecast and accounts for the forecast errors in the costs it provides.

Through the study scenarios from 2022 to 2032 the aggregated capacity of gas resources increase. The average annual gas prices modeled in the MTEP18 database are 4.36 $/MMBTU in 2022, 5.47 $/MMBTU in 2027 and 6.49 $/MMBTU in 2032.

The results of the production costs from PROMOD runs include forecast errors unless otherwise stated. Table 15 depicts the annual renewable production (MWH), Conventional resource production (MWH), system cost, cost per MWH, total NSP load MWH, wind and solar curtailment, and the NSP off system energy requirement. The Base Case is the only case where NSP is a net purchaser of power over the year. The average cost in $/MWH increases from 22.99 $/MWH in the Base Case to 42.40 $/MWH in Scenario 4.

The cost of integrating wind and solar PV based upon the forecast error is shown in Table 17. The cost of forecast error due to the integration of wind and solar PV range from 0.09 $/MWH in Scenario 1 to 0.42 $/MWH in scenario 4. The increase in renewable and reduction in traditional generation resulted in lower production costs in Scenario 4. The difference from forecast error is nearly the same in Scenario 3 as in Scenario 4. The % of cost increased over the % if cost increase of scenario 3.

Resource production by fuel type was analyzed over each of the scenarios in Table 18. Gas CT and combined cycle resources increased production as renewable penetration increased. Gas CT production increased in Scenario 1 from 349 TWH to 825 TWH in Scenario 4. Combined cycle production increased in Scenario 1 from 3,485 TWH to 12.368 TWH in Scenario 4. Coal resource production in combination with retirements decreased over the study. While coal capacity decreased from 2,479 MW in Scenario 1, to 1,054 MW in Scenario 2, to 528 MW in Scenario 3 and 4. The capacity factor of the aggregated coal resources increase as the renewable resource penetration increase from 70% in Scenario 1 to 82% in Scenario 4. This increase can be contributed to coal resource retirements that provides

production opportunity for the remaining coal resources. There is little difference in production for the other resources modeled.

An analysis of unit startups was conducted. In this analysis PROMOD produced hourly output for NSP resources of each different fuel type. The number of startups were counted in each scenario. In general the number of startups across the NSP fleet increases as renewable penetration increases. Coal resources in Scenario 4 show a decrease in startups while CC and Gas CT resources show an increase startups. Table 19 shows the number of resources by fuel type in each scenario. Table 20 shows the increase in unit startups over the year. Table 21 shows the number of resource startups over the year. Table 22 shows the average number of starts per resource type. Additional plots on number of starts can be found in the accompanying presentation.

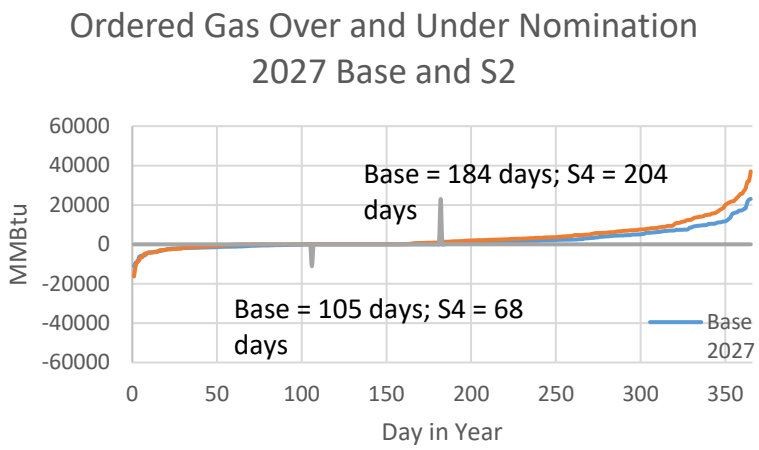
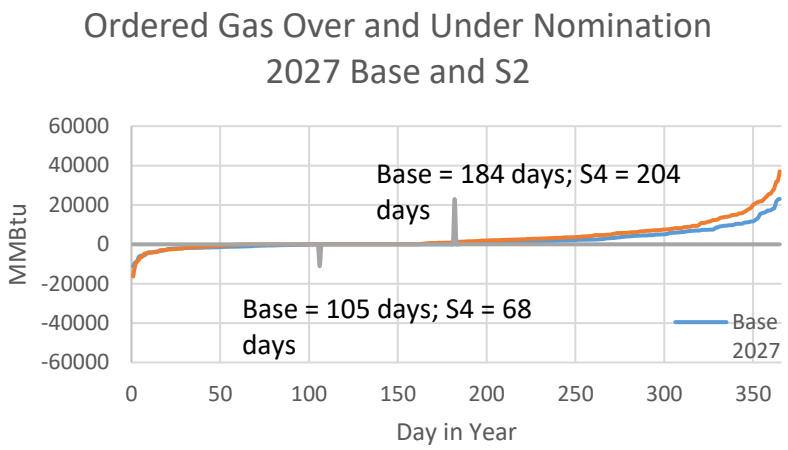
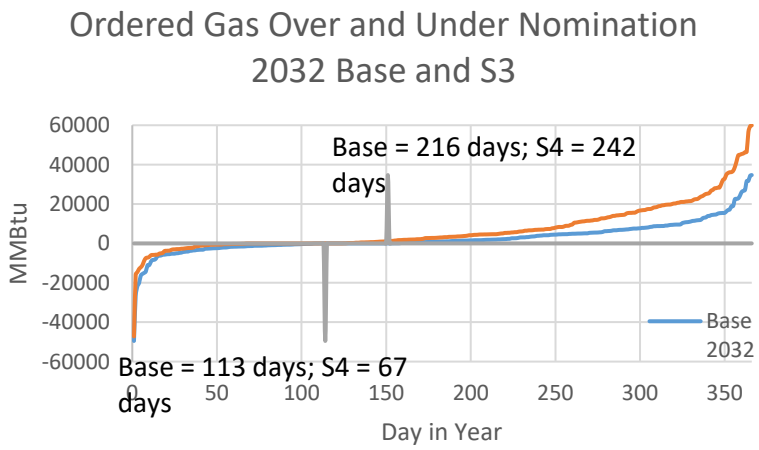
Gas Usage was evaluates by comparing the scenario runs with forecast error and without forecast error. The difference in these two runs provide estimations of gas over and underutilization. Over utilization occurs when more gas is burned than anticipated in the forecast while underutilization occurs when less gas is burned. The gas day in this analysis begins at 9:00 am Central Time. The Fuel burned in each run (Forecast Error and No Forecast Error) was computed then compared to determine the gas day for over or under utilization. The number of gas days of over nomination increases as renewable penetration increases. The plots shown are created by ordering the over and under nomination days from low to high. The blip on each curve in Figure 35 shows the number of days a nomination is low or high in each Scenario.







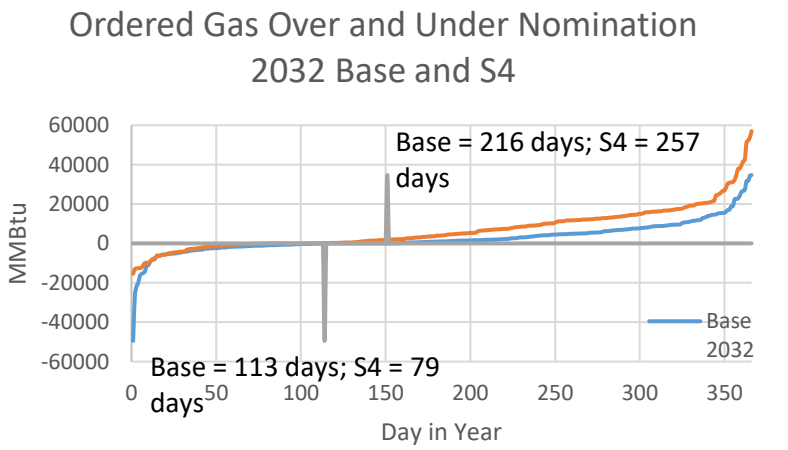


Figure 35: Over and Under Nomination for Gas Day

SECTION 9 CONCLUSIONS

The conclusions as well as findings and recommendations derived from this study are several.

- The average NSP production cost range is $22.99/MWH for the Base 2022 to $42.40/MWH for Scenario 4 (2013).
    - NSP is a net seller of power over the year in all studied scenarios.
    - Integration Cost due to forecast error ranges from 0.09 $/MWH to 0.55 $/MWH from Scenario 1 to Scenario 4.

Table 23: Summary of Project Production and Integration Costs

		Load and Production by Resource Type (GWh)				Production Cost ($/MWh)	Integration Cost Adder ($/MWh)	NSP Net Buyer/ Seller Position
Scenario	Year	NSP Load (GWh)	Wind Generation (GWh)	Solar Generation (GWh)	Other Resources (GWh)			
Base	2022	46,689	11,081	411	32,100	$22.99	---	Buyer
1	2022	46,689	17,185	2,263	31,260	$22.84	$0.09	Seller

4	2988	34.1%	6965	79.5%

- Spinning reserves increase as renewable penetration increases from 65MW for the Base (2022) to 141 MW for Scenario 4 (2032), Table 26.
    - With these spinning reserve increases there are a few hours in the year when NSP would rely on MISO for support. 36 hours with in Scenario 1 (2022) and 139 hours in Scenario 4 (2032). The maximum spinning deficiency in an hour being 43 MW and 145 MW respectively.
    - This supports the argument that the MISO operating reserve requirements will need to increase in the future to support the higher levels of renewable penetration.

Table 26: Summary of Projected Spinning Reserve Requirements

	Average Spinning Reserve Requirements (MW)			# of Hours When NSP would Rely on MISO Support(*)

Technical and Economic Potential for Combined Heat and Power (CHP) Applications in Xcel Energy's Minnesota Territory. EPRI, Palo Alto, CA: 2019. 3002016990.

ABSTRACT

Customer-sited fueled distributed generation (DG), often serving both heating and power needs, has served as a reliable source of distributed energy resources. A combination of technology improvements, project economics, policy incentives, and consumer choice in technology and energy service may impact the use of DG in the future. These changing needs and advancements have the potential to disrupt trajectories of load growth, driven by technical and economic decisions in technology adoption. Without adjustments to planning forecasts with respect to the driving factors, the forecasts may not adequately capture the range of load outcomes considered for system planning. The goal of this study is to estimate the technical and economic potential for commercial and industrial (C&I) combined heat and power (CHP) projects in the Minnesota service territory of Xcel Energy. Additionally, the expected market adoption for CHP is projected through 2039 with several sensitivity scenarios. This study serves as an update to a previous study performed in 2014.

1
STUDY OBJECTIVE AND SUMMARY

This goal of this study is to estimate the technical and economic potential for commercial and industrial (C&I) combined heat and power (CHP) projects in the Minnesota service territory of Xcel Energy. Additionally, the expected market adoption for CHP was projected through 2039 with several sensitivity scenarios. This study serves as an update to a previous study performed in 2014.

As a first step, the technical potential for CHP in Xcel Energy's Minnesota territory was analyzed using customer data furnished by Xcel Energy. Data included commercial/industrial segment, maximum demand, and annual energy consumption for customers with maximum demands of 1 MW or larger. Power-to-heat ratios are estimated based on C&I segments and serve as input to the CHPower™[1] model to estimate the technical potential for CHP applications. The resulting technical potential is broken down by segment in Table 1-1.

Table 1-1
Technical Potential in Xcel Energy Minnesota (facilities with at least 1 MW peak demand)

Sector	Sites	Sum of Peak Demand (MW)	Technical Potential (MW)
Commercial	119	289	123
Industrial	120	492	196
Total	**239**	**781**	**319**

The 319 MW of technical potential from 239 sites is relatively small compared to the 941 MW of technical potential from 628 sites in the 2014 study. According to Xcel Energy, this difference was due to a combination of changes in data processing methods and customers implementing distributed energy resources and energy efficiency measures, resulting in lower peak demands.

After establishing the customers with technical potential for CHP, economics were analyzed using the CHPower Model™. Sites with economic potential (simple payback periods of less than 10 years) were broken down by payback period and sector, with the results shown in Table 1-2.

[1] ICF, CHPower Model. Fairfax, Virginia, 2019.

Table 1-2
Economic Potential in Xcel Energy Minnesota CHP, by Sector and Payback Period

	5-7 Years		7-10 Years		Total	
Sector	**Sites**	**Economic Potential (MW)**	**Sites**	**Economic Potential (MW)**	**Sites**	**Economic Potential (MW)**
Commercial	0	0	15	31	15	30
Industrial	<15	99	<15	16	19	115
Total	**<15**	**99**	**<30**	**47**	**34**	**145**

Overall there is an estimated 145 MW of economic potential CHP capacity that could achieve payback periods under 10 years. All of the economic potential came from sites capable of installing CHP sized larger than 1 MW. The economic potential in Minnesota is broken down by size range and payback period in Figure 1-1.

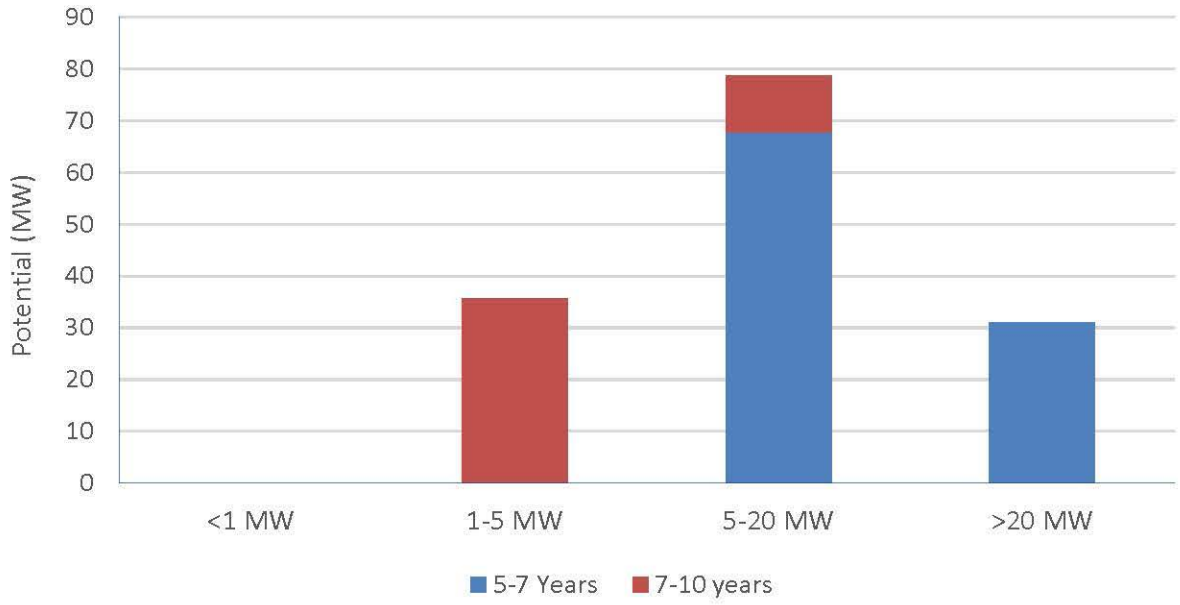

Figure 1-1
Economic Potential in Xcel Energy Minnesota by CHP Size Range and Payback

Out of the 145 MW of economic potential, 114 MW comes from industrial manufacturing facilities that tend to require a payback of less than five years on their energy investments in order to move forward with a project. For most of these customers, some form of large incentive would need to be available or they would need to have a high resilience need before they would consider installing a CHP system.

A market adoption analysis through 2039 was performed, and the base case results show 43 MW of total adoption (see Figure 1-2).

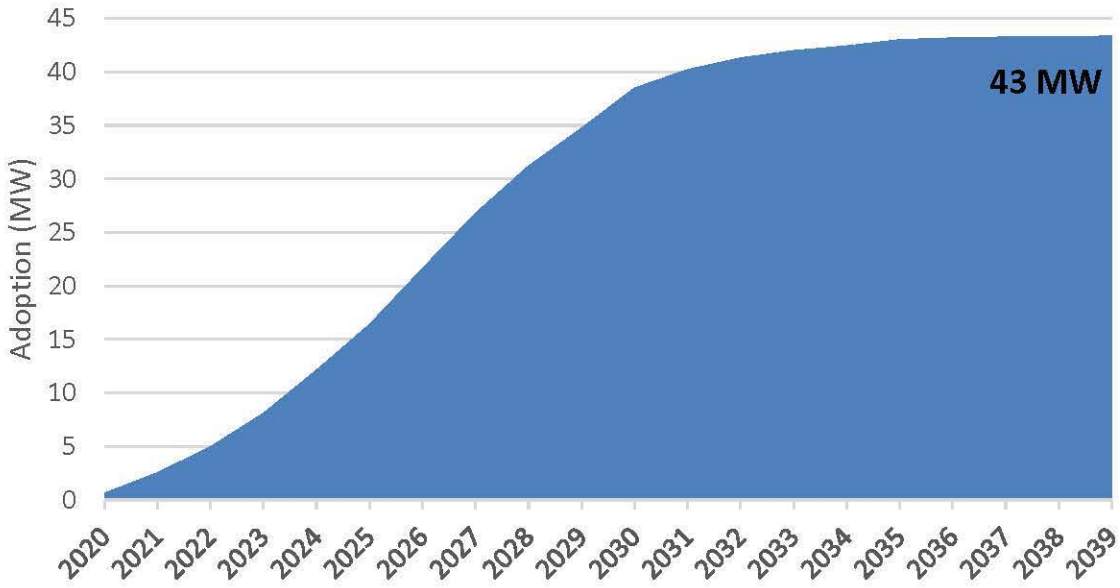

Figure 1-2
Estimated CHP Market Adoption in Minnesota through 2039

Sensitivities

Several sensitivities were performed for this analysis, including capital cost reductions, elimination of standby charges, and alternate electricity and natural gas escalation rates. The results were as follows:

- **Capital cost reduction** – At a 10% capital cost reduction for CHP installations, which mimics the current federal Investment Tax Credit, the overall impact on economic potential and market adoption was fairly minimal. At 30%, the economics for all sites improved, with economic potential increased by 50 MW and expected market adoption increased by 36 MW.
- **Eliminating standby charges** – This improved project economics for all facilities, reducing the payback period for several sites. The economic potential increased by 23 MW, but stronger long-term economics from the elimination of these charges would make facilities more likely to adopt, increasing estimated market adoption by 18 MW.
- **Using EIA escalation rates for electricity and natural gas** – Compared to Xcel Energy's internal forecasts, the EIA escalation rates are less favorable for CHP applications because they have natural gas prices increasing faster than electricity prices – total estimated market adoption decreased by 2 MW.
- **Simulating lower natural gas rates** – Instead of the natural gas escalation rate provided by Xcel Energy, there was no price escalation applied to natural gas rates. This improved CHP project economics, leading to a 9 MW increase in the estimated 20-year market adoption.

For all sensitivity scenarios considered, the total range of CHP market adoption through 2039 was between 41 MW and 79 MW. The results of the estimated 20-year market adoption for each sensitivity scenario are summarized in Table 1-3.

Table 1-3
Market Adoption in Xcel Energy Minnesota CHP, by Sensitivity Scenario

Sensitivity Scenario	Estimated 20-Year Adoption (MW)
Base Case	43
10% Capital Cost Reduction	52
30% Capital Cost Reduction	79
No Standby Charges	61
EIA Escalation Rates	41
Low Natural Gas Prices	52

Finally, the impact on carbon dioxide emissions was examined for both the base case market adoption and the 30% installed cost reduction sensitivity, to show how a relatively large CHP incentive might affect carbon emissions. With the expected CHP adoption, 42,000 tons of CO_2 would be reduced on an annual basis for the base case, compared to 66,000 tons with a 30% capital cost reduction.

Key Takeaways

The following are important findings from the analysis:

- Technical potential: 319 MW across 239 sites.
- Economic potential for base case: 145 MW of CHP, based on Xcel Energy forecasts for electricity/gas escalation, with payback periods ranging from 5 to 10 years.
- Market adoption: 43 MW is anticipated to be adopted through 2039 in the base case, with 39 MW being installed by 2030.
- A 30 percent cost reduction, in the form of a tax credit or grant, would have a large impact on economics, adding 36 MW of expected adoption through 2039, for a total of 79 MW.
- Removing standby rates improves payback periods, adding 18 MW of adoption through 2039.
- CHP installations could lead to a significant reduction in greenhouse gas emissions compared to separate heat and utility power, although emissions will decline over time as the grid becomes cleaner.
- There may be potential benefits to be explored or considered by offering utility-owned CHP systems to large customers with high CHP potential.

2
ASSESSMENT OF DG AND CHP TECHNICAL AND ECONOMIC POTENTIAL IN XCEL ENERGY'S MINNESOTA TERRITORY

As an update to a 2014 assessment of DG and CHP potential, this study aims to provide information on the projected impacts of natural gas-fueled DG and CHP applications in Xcel Energy's service areas, focusing on the large C&I customer base in the Minnesota service territory.

The objectives of the study were to:

- Estimate and analyze technical and economic potential for natural gas distributed generation in C&I end user applications.
- Identify key C&I segments where DG CHP applications could be cost effective for end-users.
- Evaluate the impact of sensitivity scenarios on expected market adoption.
- Present findings and results for the Minnesota service territories.

The focus of this study is on natural gas CHP applications that can utilize waste heat to displace site thermal loads. CHP systems are more efficient and economical than power-only generators. The 2014 study found that natural gas generators in Minnesota were not economical unless they incorporated heat recovery and utilization in a CHP configuration. Additionally, most C&I facilities with significant electric requirements also have a sizable thermal demand that can be served by CHP.

Technical Potential

This study estimated the technical potential for natural gas CHP applications in Xcel Energy's Minnesota service territory. Facility counts and sizes were provided by Xcel Energy, using actual customer data for electric demand (kW) and annual electricity consumption (kWh). This data, along with industry-specific thermal load estimates, is used to approximate the potential size for baseload CHP systems at each customer site. The data was anonymized so that customer names and addresses were not provided. The resulting technical potential estimates are broken down by market sector in Table 2-1.

Table 2-1
Technical Potential in Xcel Energy Minnesota (facilities with at least 1 MW peak demand)

Sector	Sites	Sum of Peak Demand (MW)	Technical Potential (MW)
Commercial	119	289	123
Industrial	120	492	196
Total	**239**	**781**	**319**

The 319 MW of technical potential from 239 sites is relatively small compared to the 941 MW of technical potential from 628 sites in the 2014 study. According to Xcel Energy, this difference was due to a combination of changes in data processing methods and customers implementing distributed energy resources and energy efficiency measures, resulting in lower peak demands.

Based on the economic CHP sizing, over half of these sites could only support CHP systems smaller than 1 MW in size. In this size range, equipment costs are higher on a per-kW basis, so project economics tend to not be as strong. The technical potential in Minnesota (based on economic CHP sizing) is broken down by size range in Table 2-2.

Table 2-2
Technical Potential in Xcel Energy Minnesota by Sector and CHP Size Range

	<1 MW		1-5 MW		5-20 MW		>20 MW	
Sector	**Sites**	**Technical Potential (MW)**	**Sites**	**Technical Potential (MW)**	**Sites**	**Technical Potential (MW)**	**Sites**	**Technical Potential (MW)**
Commercial	76	37	42	75	<15	11	0	0
Industrial	79	29	33	68	<15	68	<15	31
Total	**155**	**66**	**75**	**143**	**<30**	**79**	**<15**	**31**

All of these facilities were analyzed for economic potential, to determine how many sites would be capable of a 10-year or less payback period.

Economic Potential

Installed capital cost, maintenance costs, and performance information for the CHP systems were provided by EPRI from a Request for Information process that was deployed for the recent national study, using typical price and performance data for CHP units across three different size ranges[2]:

1. 100 – 1,000 kW (Medium Commercial/Light Industrial)
2. 1,000 – 5,000 kW (Large Commercial/Medium Industrial)
3. > 5,000 kW (Large Industrial)

The costs were adjusted to reflect inflation rates since the data was provided in 2014.[3] The price and performance data for engines, turbines and fuel cells in these size ranges are shown in Table 2-3.

[2] EPRI Report Natural Gas Distributed Generation Options Cost and Market Benchmarking Assessment 3002004191, October 2014.

[3] 6.1% inflation applied from 2014 to 2018 (US Inflation Calculator, https://www.usinflationcalculator.com); 1.9% 2018 inflation applied annually to 2020 (analysis starts in 2020).

Table 2-3
Price and Performance Data Used in Economic Analysis[4]

	100 - 1,000 kW			1 - 5 MW		5 - 50 MW	
	Engine	Fuel Cell	MT	Engine	Turbine	Engine	Turbine
Installed Cost ($/kW)	$3,310	$6,610	$3,080	$1,980	$2,420	$1,210	$1,380
Maintenance ($/kWh)	0.022	0.028	0.012	0.018	0.020	0.011	0.010
Electric Efficiency (HHV)	29.0%	45.0%	27.0%	37.0%	34.0%	41.0%	32.0%
CHP Efficiency (HHV)	79.0%	83.0%	65.0%	80.0%	68.0%	77.0%	74.0%

The Federal Investment Tax Credit for CHP – scheduled to ramp down from 10% (current rate) to 6% in 2021 and 0% after – was not incorporated into the economic potential results. State average natural gas prices[5] and Xcel Energy's current electricity tariffs were inputs to the model which estimated electricity bills before and after CHP is installed, considering the effect of standby charges, demand charges, and time-of-use components. Then, the installed cost of CHP was compared to the net annual savings when considering maintenance, fuel purchases, and energy bill savings. Economics were analyzed on a site-by-site basis using ICF's CHPower Model™, with the full assumptions and methodology outlined in Appendix A.

Overall, 145 MW of economic potential was found in Xcel Energy's Minnesota service territory, with 99 MW showing payback periods in the range of 5-7 years and the remainder in the range of 7-10 years. Economic potential comes from a mixture of large manufacturing facilities, mining operations, paper mills, chemical plants, commercial office buildings, and other commercial facilities. The results are broken down by sector and payback period range in Table 2-4.

Table 2-4
Economic Potential in Xcel Energy Minnesota by Sector and Payback Period Range

	5-7 Years		7-10 Years		Total	
Sector	Sites	Economic Potential (MW)	Sites	Economic Potential (MW)	Sites	Economic Potential (MW)
Commercial	0	0	15	31	15	30
Industrial	<15	99	<15	16	19	115
Total	**<15**	**99**	**<30**	**47**	**34**	**145**

All of the economic potential comes from sites capable of installing CHP sized larger than 1 MW. While the economics for hospitals and college campuses may not be as strong as large industrial facilities, they have typically been more willing to take on longer payback periods. Industrial facilities tend to require payback periods under five years. For hospitals and college

[4] EPRI Report Natural Gas Distributed Generation Options Cost and Market Benchmarking Assessment 3002004191, October 2014.

[5] The lower of the average industrial gas rate or average citygate price plus $1/MMBtu (EIA average 2017 prices)

campuses, their future is more certain than industrial sites, and they may take on projects with payback periods up to 10 years. Figure 2-1 provides a graphical representation of the economic potential by segment and payback period.

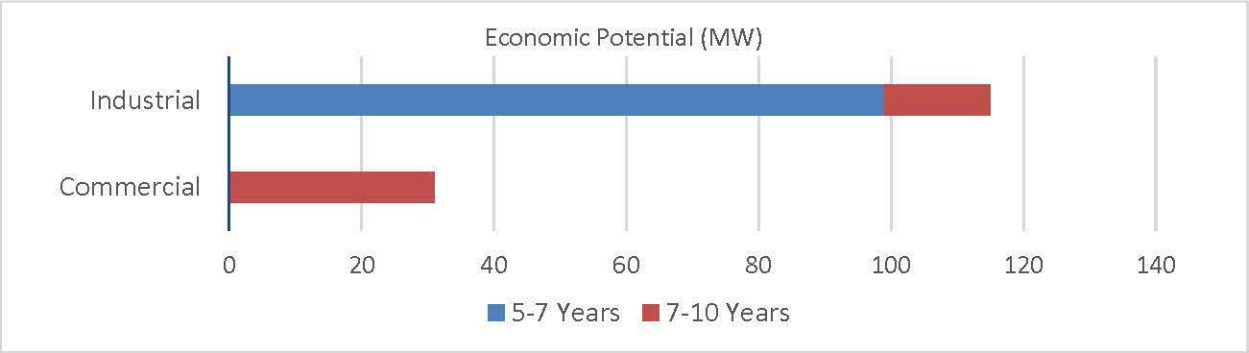

Figure 2-1
Economic Potential in Xcel Energy Minnesota by Sector and Payback Period

The economic potential in Xcel Energy's Minnesota territory is broken down by size range and payback period in Figure 2-2. It should be noted that all of the potential in the >20 MW range comes from fewer than 15 facilities.

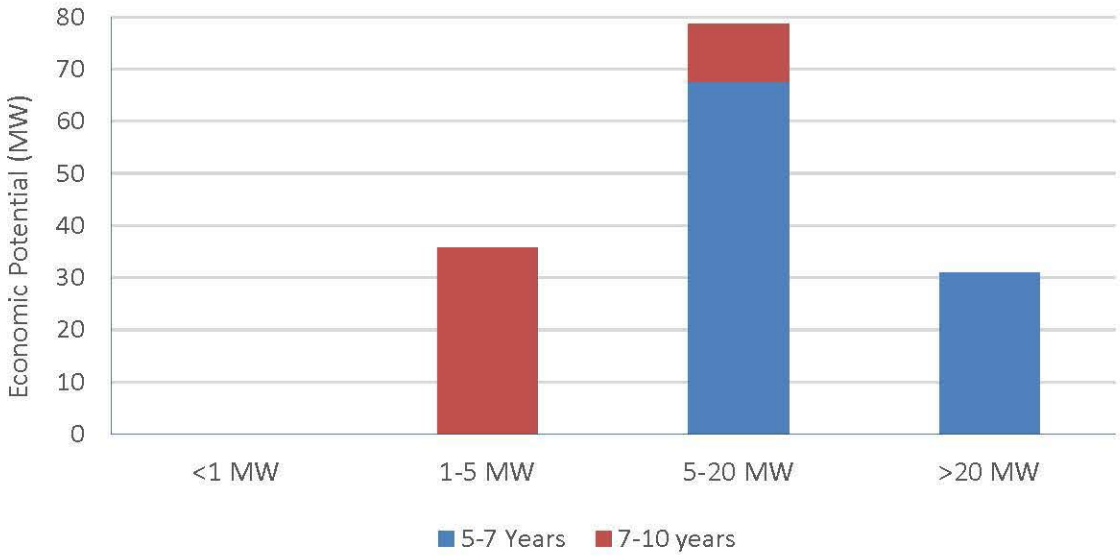

Figure 2-2
Economic Potential in Xcel Energy Minnesota by CHP Size Range and Payback Period

The economic potential analysis showed that project economics are strongest at large, high load factor facilities.

Market Adoption Analysis

The CHPower model™ can estimate the expected adoption of CHP over time. First, market acceptance percentages are applied to each potential installation, based on the sector and payback period. Facility owners in the commercial (and institutional) sectors are more likely to accept

projects with longer payback periods compared to industrial facility owners. Market acceptance curves were developed based on a combination of survey results (including the Primen survey used in the 2014 analysis[6]), interviews with current and potential CHP customers, and experience in the marketplace. The market acceptance curves are shown in Figure 2-3.

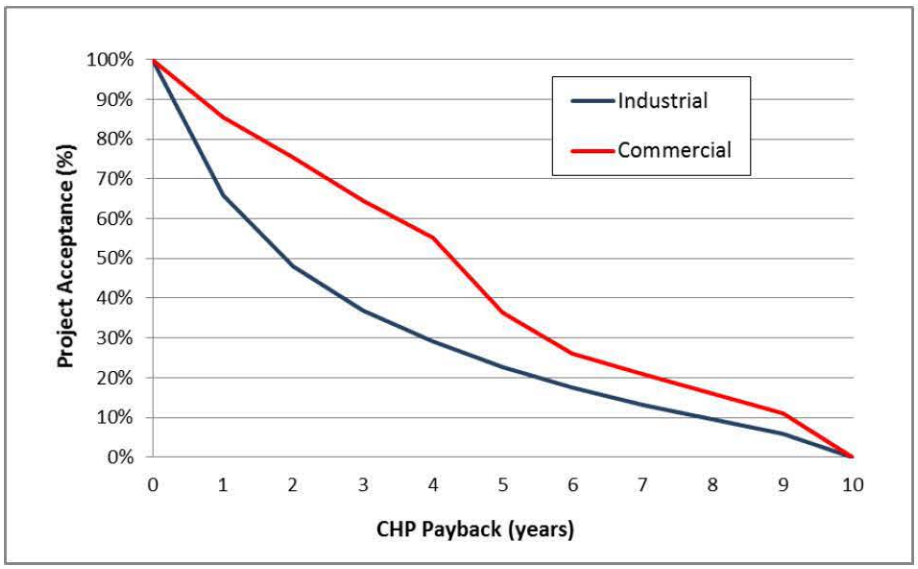

Figure 2-3
Market Acceptance Curves by Payback Period and Sector

The market-accepted potential defines the boundaries of CHP adoption, based on current market conditions. To estimate adoption over time, the model applied a Bass Diffusion model, which includes electricity and natural gas rate escalation with Xcel Energy-provided data, along with industry-specific market growth estimates from the 2018 EIA Annual Energy Outlook.[7] Market adoption was estimated on an annual basis with these changing factors built into the CHPower model calculations. The results for the base case scenario are shown in Figure 2-4, with an estimated 43 MW of CHP adoption from 2020 through 2039.

[6] *Converting Distributed Energy Prospects into Customers*, Primen, December 2003 (EPRI Number 1010294)

[7] U.S. Energy Information Administration, Annual Energy Outlook, 2018, https://www.eia.gov/outlooks/archive/aeo18/

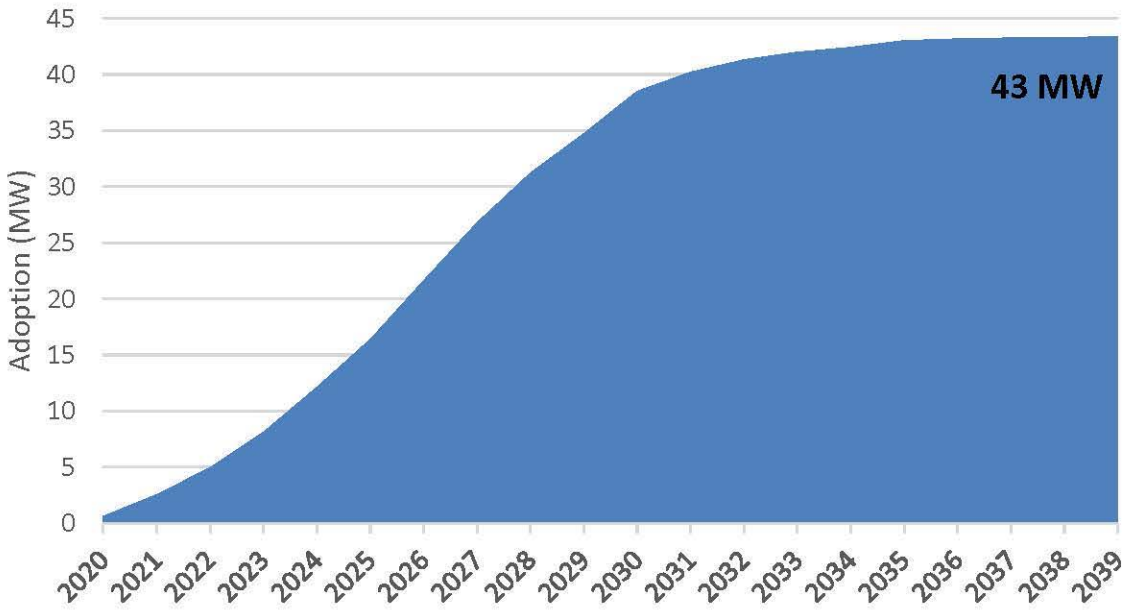

Figure 2-4
Xcel Energy Minnesota Base Case Market Adoption Through 2039

The majority of expected adoption occurs between 2020 and 2030. After 2030, adoption slows due to market limitations and less favorable economics from higher gas prices. Most of this adoption occurs in fewer than 15 sites. Figure 2-5 shows the estimated 20-year adoption by CHP size range. Overall, fewer than 15 sites are expected to adopt CHP, mostly within the 1-5 MW size range.

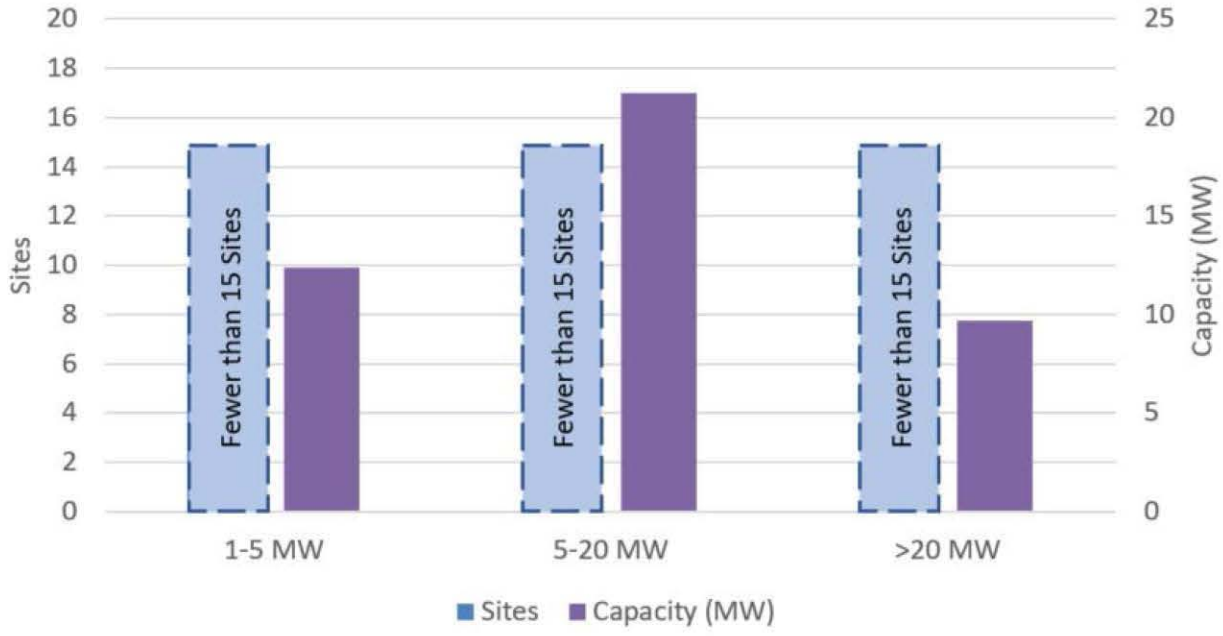

Figure 2-5
Xcel Energy Minnesota Base Case Market Adoption through 2039 by CHP Size Range

Sensitivity Analysis

Five sensitivities were performed for this analysis:

1. capital (installed) costs reduced by 10 percent to show the effect of a CHP incentive
2. capital (installed) costs reduced by 30 percent to show the effect of a larger CHP incentive
3. removal of standby charges
4. using EIA escalation rates for electricity and natural gas
5. removing the escalation of natural gas prices

For each sensitivity, the effects on economic potential and estimated market adoption are shown.

Sensitivity: 10% Installed Cost Reduction

The first sensitivity reduced the installed cost of CHP systems by 10 percent, representing a small government or utility capital incentive. With a 10 percent capital cost reduction, there is a modest increase of 7 MW of economic potential, all found in sites 1-5 MW in size. This new economic potential is found in manufacturing facilities, commercial buildings, colleges/universities, and hotels. While there was not much of an increase in economic potential, the 10 percent cost reduction shortens the payback period of the existing economic potential, moving 65 MW of potential to a payback period under five years (all in sites above 5 MW). The economic potential for this sensitivity is broken down by sector and payback period in Table 2-5.

Table 2-5
Sensitivity: Economic Potential in Xcel Energy Minnesota with 10% CHP Cost Reduction

	<5 Years		5-7 Years		7-10 Years		Total	
Sector	**Sites**	**Economic Potential (MW)**	**Sites**	**Economic Potential (MW)**	**Sites**	**Economic Potential (MW)**	**Sites**	**Economic Potential (MW)**
Commercial	0	0	<15	14	16	21	19	35
Industrial	<15	65	<15	41	<15	11	21	118
Total	**<15**	**65**	**<30**	**55**	**<30**	**32**	**40**	**153**

With a 10 percent capital cost reduction applied, there is a more noticeable change to the total estimated market adoption compared to the total economic potential. Under this sensitivity, expected market adoption increases from 43 MW to 52 MW through 2039, following a similar trend as the base case. The new 20-year market adoption curve with the 10 percent cost reduction can be seen in Figure 2-6.

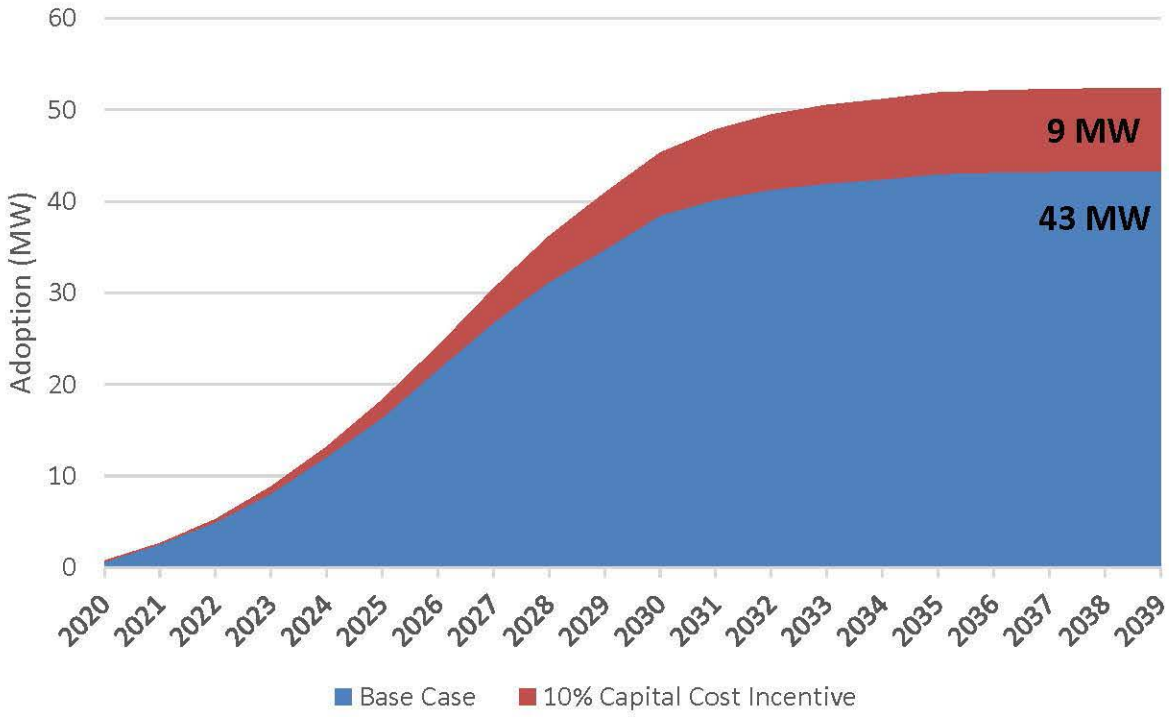

Figure 2-6
Sensitivity: Market Adoption through 2039 with 10% CHP Cost Reduction

Sensitivity: 30% Installed Cost Reduction

The next sensitivity reduced the installed cost of CHP systems by 30 percent, representing incentives similar to those from a larger government or utility capital incentive. With a 30 percent capital cost reduction, there is a much larger impact on economic potential – a total increase of 50 MW. This new economic potential is found in sites 1-5 MW in size across several industrial and commercial sectors. The 30 percent cost reduction also shortens the payback period of much of the existing economic potential. Nearly all of the economic potential at sites larger than 5 MW would now have payback periods under 5 years. The economic potential for this sensitivity is broken down by sector and payback period in Table 2-6.

Table 2-6
Sensitivity: Economic Potential in Xcel Energy Minnesota with 30% CHP Cost Reduction

	<5 Years		5-7 Years		7-10 Years		Total	
Sector	**Sites**	**Economic Potential (MW)**	**Sites**	**Economic Potential (MW)**	**Sites**	**Economic Potential (MW)**	**Sites**	**Economic Potential (MW)**
Commercial	0	0	15	31	16	30	31	61
Industrial	<15	99	<15	16	<15	20	28	134
Total	**<15**	**99**	**<30**	**47**	**<30**	**50**	**59**	**195**

Using a 30 percent capital cost reduction, there is also a large change to the total estimated market adoption. As expected, the additional expected market adoption is more than double that provided by the 10 percent capital cost reduction. Under this sensitivity, expected market adoption increases from 43 MW to 79 MW through 2039, the largest expected market adoption under any of the sensitivities. The new 20-year market adoption curve with the 30 percent cost reduction can be seen in Figure 2-7.

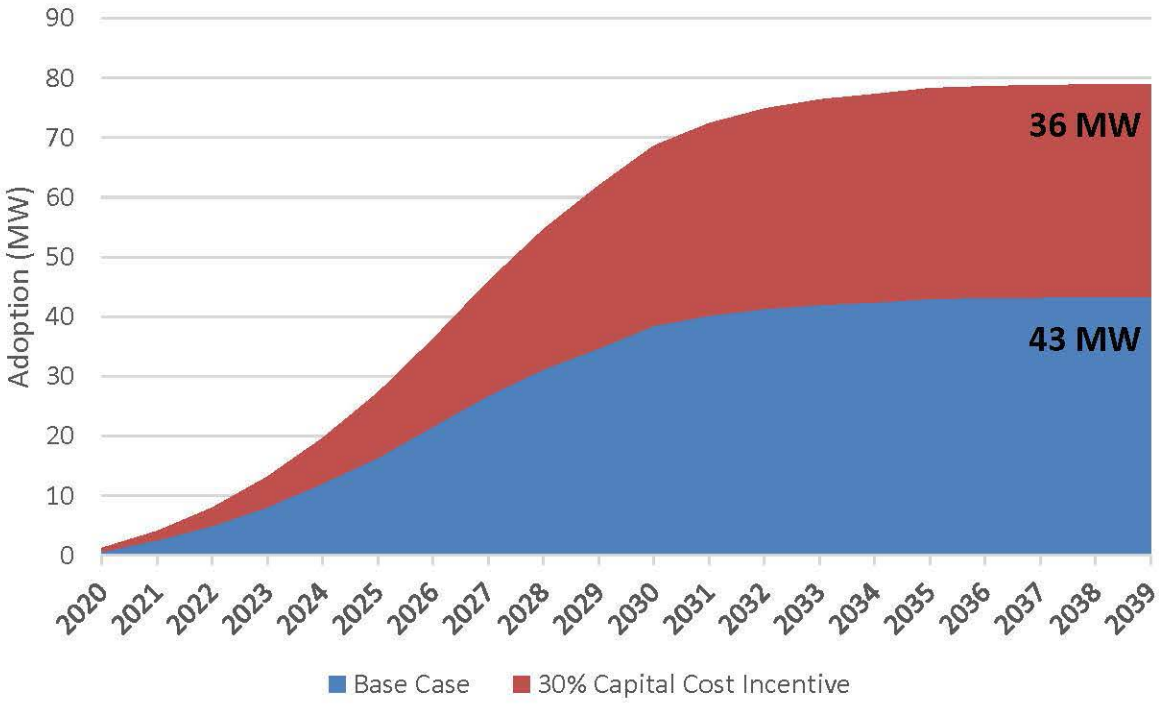

Figure 2-7
Sensitivity: Market Adoption through 2039 with 30% CHP Cost Reduction

Sensitivity: Removal of Standby Charges

Standby charges were modeled using the contract demand charge, assuming all maintenance occurs on a scheduled basis, and no unscheduled downtime or maintenance for the CHP unit that would add additional charges. The contract demand charges, in dollars per kW of CHP system size, are:

- $3.00 per kW for customers receiving service at secondary voltage (assumed to be sites with a maximum demand of less than 3,000 kW),
- $2.20 per kW for customers receiving service at primary voltage (maximum demand of 3,000 – 30,000 kW), or
- $0.65 per kW for customers receiving service at transmission-level voltage (maximum demand of 30,000 kW or higher).

There is a further reduction in standby charges for customers at the sub-transmission level, but for the purposes of this analysis, all customers were assumed to be on either secondary or primary voltage lines.

When the standby charges were removed, economics were improved, resulting in more economic potential and shorter payback periods. 23 MW of economic potential was added in the state, all at sites under 5 MW. Additionally, many of the large industrial facilities over 5 MW that were in the 5-7 year payback range have shifted to <5 year paybacks. The economic potential with no standby charges is presented by segment and payback period in Table 2-7.

Table 2-7
Sensitivity: Economic Potential in Xcel Energy Minnesota with No Standby Charges

	<5 Years		5-7 Years		7-10 Years		Total	
Sector	**Sites**	**Economic Potential (MW)**	**Sites**	**Economic Potential (MW)**	**Sites**	**Economic Potential (MW)**	**Sites**	**Economic Potential (MW)**
Commercial	0	0	<15	14	19	25	22	39
Industrial	<15	65	<15	41	<15	23	26	130
Total	**<15**	**65**	**<15**	**55**	<40	**48**	**48**	**169**

The removal of standby charges had a greater impact on market adoption trends than on the economic potential of sites, due to the longer-term benefits of reducing these costs. Under this sensitivity, expected market adoption increases from 43 MW to 61 MW through 2039. The new 20-year market adoption curve without standby rates can be seen in Figure 2-8.

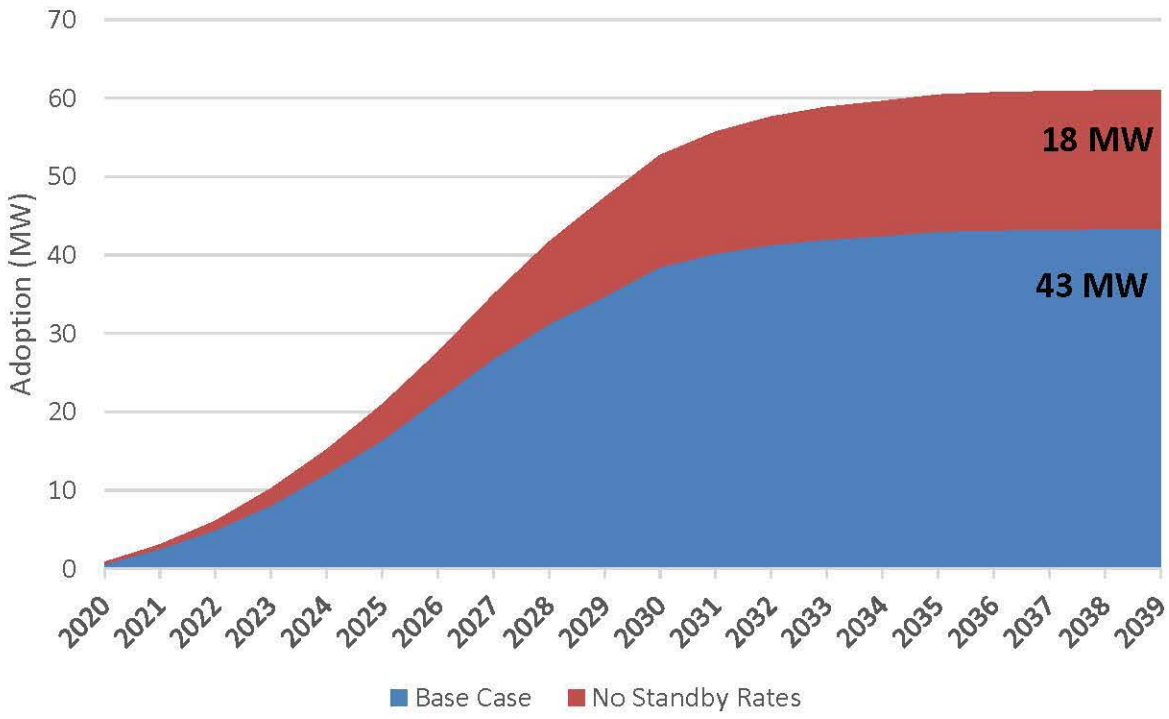

Figure 2-8
Sensitivity: Market Adoption through 2039 with No Standby Charges

Sensitivity: EIA Escalation Rates

Instead of the energy price escalation rates provided by Xcel Energy, the Energy Information Administration's projected escalation rates from the 2019 Annual Energy Outlook were used. With the EIA rates, both electricity (2.23%, compared to 2.70%) and natural gas (3.30%, compared to 4.15%) are projected to escalate at slower rates, leaving little impact on the base case results. This showed in the economic analysis, where there was no change in the economic potential compared to the base case.

However, using the EIA escalation rates did impact the expected 20-year market adoption. Because of the drop in electricity price growth, the economics for CHP projects worsened, leading to a small drop in the estimated adoption. Under this sensitivity, expected market adoption decreased from 43 MW to 41 MW through 2039. The new 20-year market adoption curve with the EIA escalation rates can be seen in Figure 2-9.

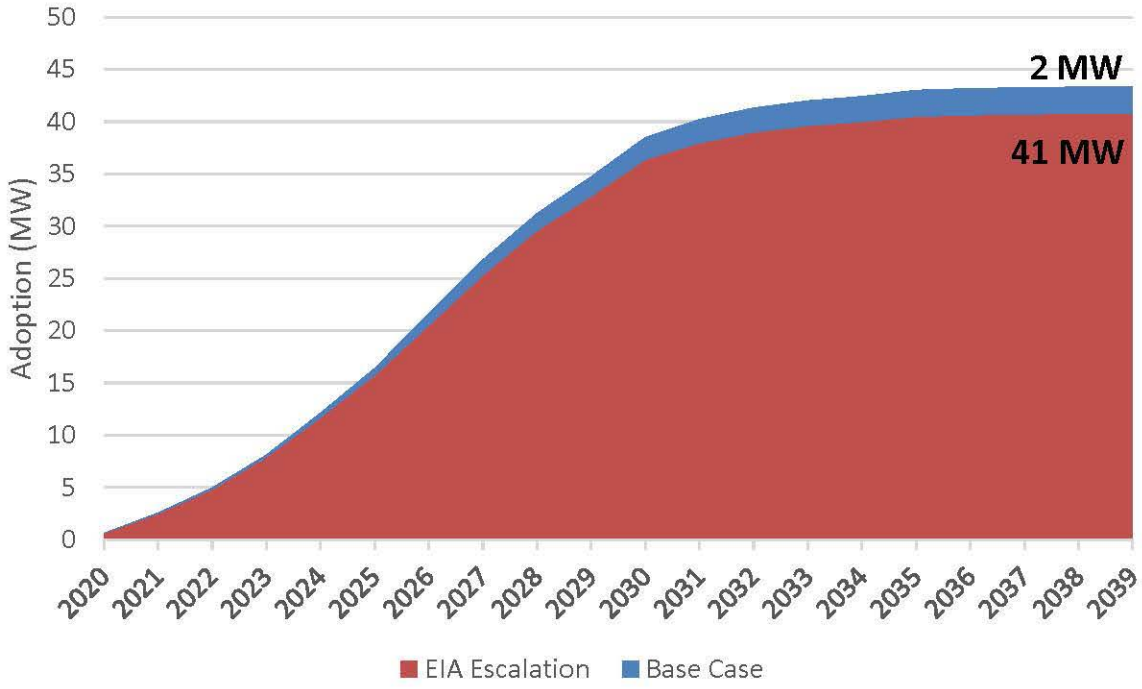

Figure 2-9
Sensitivity: Market Adoption through 2039 with EIA Escalation Rates

Sensitivity: Low Natural Gas Prices

Instead of using the natural gas escalation rate provided by Xcel Energy, there was no price escalation applied to natural gas rates in this sensitivity analysis, to mimic the impact of natural gas prices remaining lower than projected. This had no impact on the economic potential, with no difference in potential from the base case.

However, like with the EIA escalation rates, there was an impact on the expected 20-year market adoption. As expected, with lower gas prices, the economics for CHP projects improves, resulting in a sizeable increase in the estimated adoption. Under this sensitivity, expected market

adoption increased from 43 MW to 52 MW in 2039. The new 20-year market adoption curve with low natural gas prices can be seen in Figure 2-10.

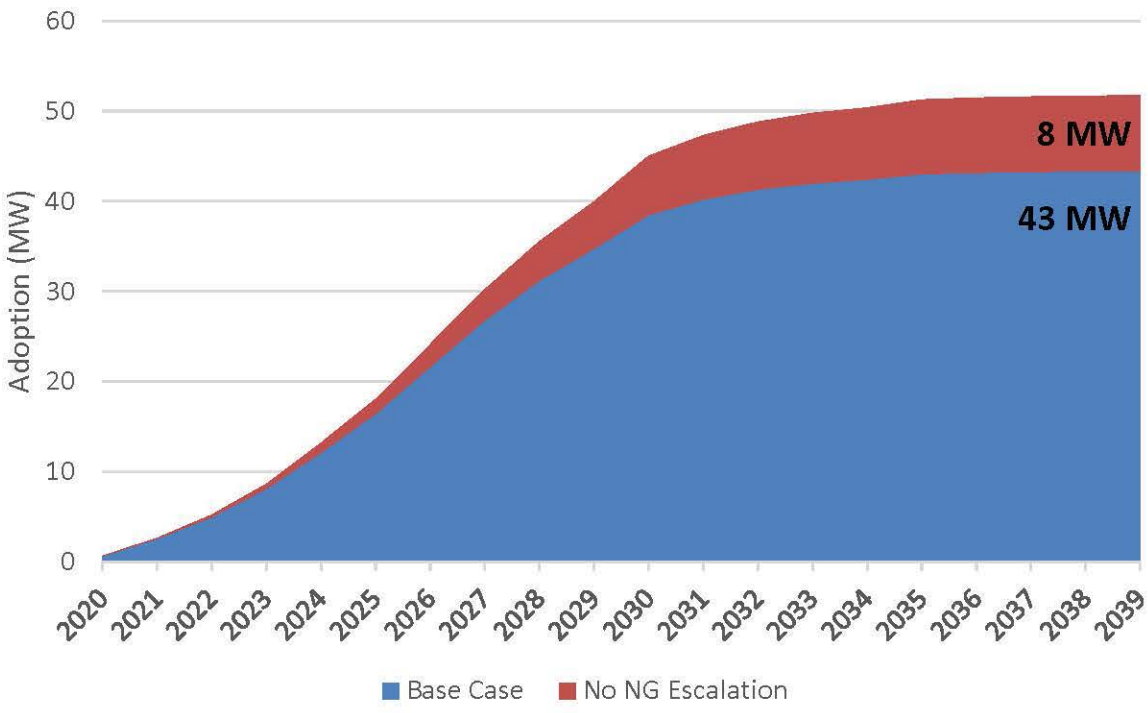

Figure 2-10
Sensitivity: Market Adoption through 2039 with Low Natural Gas Prices

Impact of Adopted CHP on CO_2 Emissions

Efficient CHP systems have a positive impact on CO_2 emissions compared to separate heat and utility power. When a baseload CHP system comes online, demand is reduced and utilities turn down fossil fuel generators in response. For baseload CHP, EPA guidance is to use the eGRID average fossil fuel emissions rate for displaced utility electricity.[8] For Minnesota, the average fossil fuel emissions rate is estimated at 1,854 lbs/MWh. In addition, transmission and distribution line losses produce an average loss of 5.13 percent for delivered electricity. For the customer, natural gas combustion – both for CHP fuel and boiler fuel – produces approximately 117 lbs CO_2 per MMBtu of fuel consumed. However, Xcel Energy recently announced an initiative to become 100 percent carbon-free by 2050, so the grid mix is expected to change significantly over the next twenty years. Between 2030 and 2040, Xcel Energy is expected to retire its coal plants, leaving only natural gas generators to accompany zero-emission nuclear/hydro/renewable resources.

[8] U.S. Environmental Protection Agency, Combined Heat and Power Partnership, Fuel and Carbon Dioxide Emissions Savings Calculation Methodology for Combined Heat and Power Systems, February 2015, https://www.epa.gov/chp/fuel-and-carbon-dioxide-emissions-savings-calculation-methodology-combined-heat-and-power

These factors were combined to develop an estimate of potential emission reductions from expected CHP deployments, both for the base case and the 30% capital cost reduction scenario. The results of this analysis are shown in Figure 2-11. The dotted lines represent the estimated emissions savings using current marginal utility emission rates, while the solid lines represent the estimated emissions savings with Xcel Energy's planned reductions in fossil fuel generation.

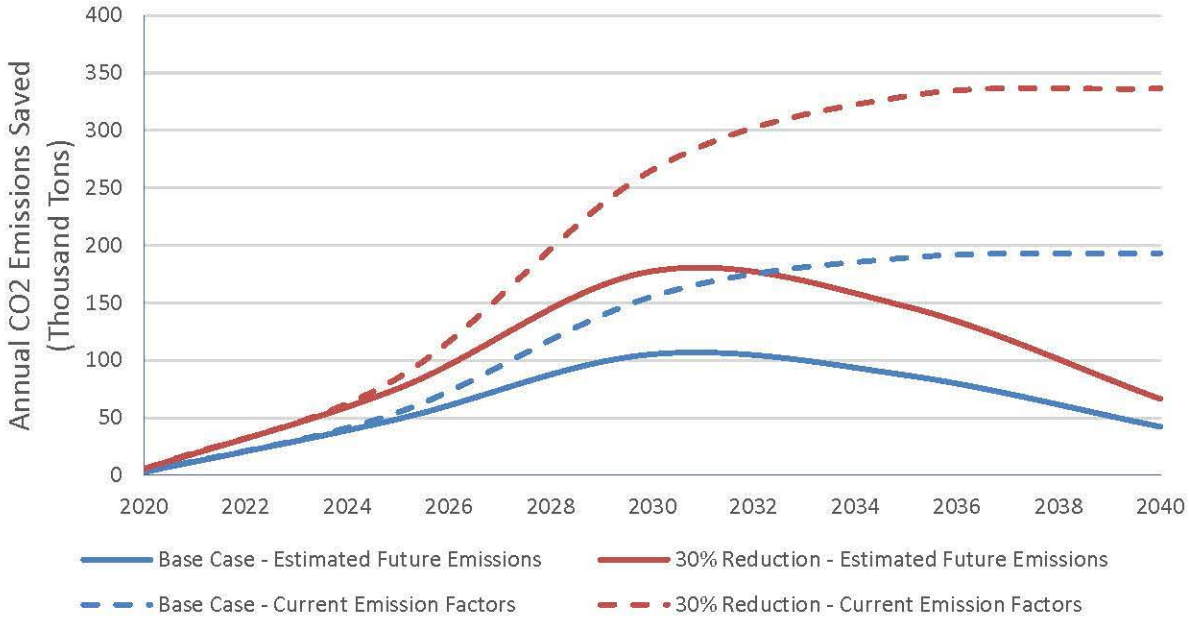

Figure 2-11
Annual Impact of Adopted CHP on Carbon Dioxide Emissions by 2040

Considering the potential impact on CO_2 emissions with 43 MW of base case adoption, an estimated 42,000 tons of CO_2 would be reduced on an annual basis by 2040, down from a maximum of approximately 108,000 tons in 2031. Looking at the increased adoption from deploying a 30 percent cost reduction, a total of 66,000 tons of CO_2 would be avoided on an annual basis by 2040, down from a maximum of 180,000 tons in 2031. While emissions reductions from CHP will be lessened over time compared to Xcel Energy's cleaner grid, there is still expected to be a significant amount of greenhouse gas savings from CHP installations that are installed over the next ten years.

3
CONCLUSION

This study estimates a total of 319 MW of technical potential from 239 sites and 145 MW of economic CHP potential in Xcel Energy's Minnesota service territory. Under current market conditions, large facilities that can install CHP systems over 5 MW in size have the strongest project economics for CHP applications, with payback periods ranging from 5-7 years. Project economics are not attractive for most potential industrial customers, who tend to desire payback periods of five years or less, so CHP adoption is likely to be a relatively slow process in these segments. Under the base case scenario, about 43 MW of adopted CHP is expected through 2039.

When installed costs for CHP systems are reduced by 30 percent, some sites can achieve payback periods below five years, and an additional 36 MW of CHP would likely be adopted through 2039. Removing standby rates has a positive effect on project economics, with an additional 18 MW of expected adoption. Using the EIA's predicted escalation rates for the U.S., the estimated 20-year adoption is reduced from 43 MW to 41 MW. Finally, low natural gas prices over the next 20 years would lead to a modest increase in estimated adoption, from 43 MW to 52 MW.

Overall, the effect of CHP adoption on Xcel Energy's Minnesota territory should be relatively modest in the foreseeable future given current conditions, with economics not strong enough to encourage more widespread adoption. State or utility incentives could speed up adoption, but the ceiling for total economic CHP potential is currently estimated to be less than 150 MW. Even at this relatively modest adoption rate, customers switching to self-generation through CHP can impact current load growth forecasts. There may be potential benefits to be explored or considered by offering utility-owned CHP systems to large customers with high CHP potential. There are a growing number of utilities who are developing rate-based utility owned CHP systems at customer sites to provide customers with energy cost savings on thermal energy, increased resilience, and economic development opportunities.[9]

A
ASSUMPTIONS AND METHODOLOGY FOR CHPOWER MODEL

The CHPower Model

The market analysis of DG/CHP systems was performed using ICF's CHPower Model[10]. This spreadsheet-based model is used to evaluate the technical, economic, and market potential for combined heat and power (CHP) applications across the United States and Canada. The model determines which combination of size, rate schedule, and operating mode is the most economical, and forecasts the commercial and industrial facilities most likely to install CHP systems based on cash flows and simple payback. The model also determines the cumulative CHP market penetration over an analysis timeframe, and provides long-term market forecast for CHP systems operating in commercial, institutional, and industrial sectors. The database of sites for use in the model was provided by Xcel Energy. Figure A-1 illustrates how the CHPower model organizes the key data inputs, performs calculations, and generates the desired outputs.

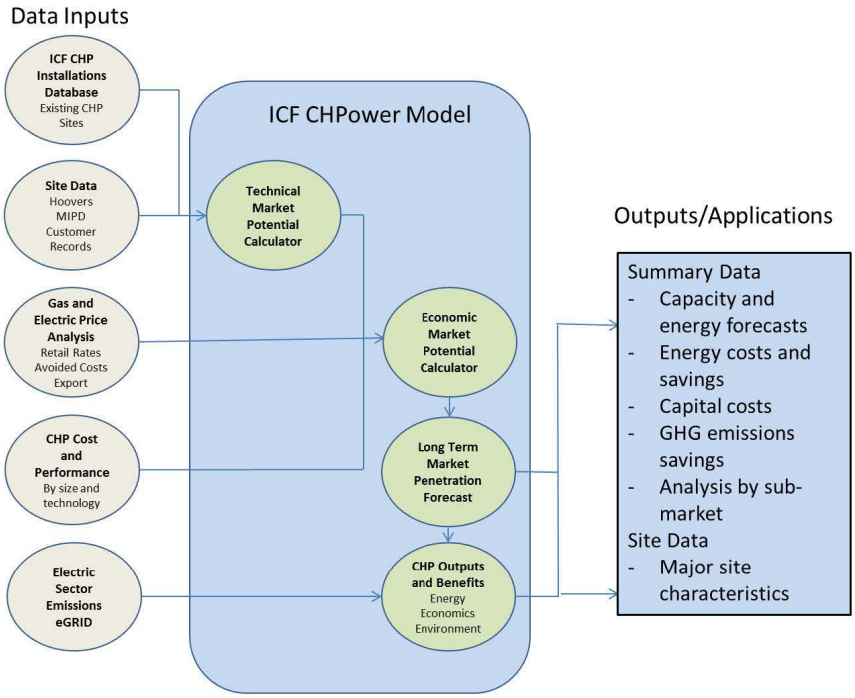

Figure A-1
CHPower Model

[10] ICF, CHPower Model. Fairfax, Virginia, 2019.

The CHPower model has been used for a variety of different geographic, economic, and technical scenarios on projects for utilities, equipment manufacturers, and research organizations. For this effort, the CHPower model was configured to:

- Evaluate the potential for CHP in Xcel Energy's Minnesota and Colorado territory with provided customer data
- Examine the potential for DG/CHP applications at a variety of commercial and industrial sites
- Process the costs and benefits for each DG/CHP unit at each site (versus utility power) and determine the DG/CHP system with the optimal payback period for each site that is analyzed for five different sensitivity scenarios
- Forecast CHP adoption over the 20-year analysis timeframe in Xcel Energy's Minnesota and Colorado territory
- Calculate estimated CO_2 emissions reductions for each site and for each sensitivity over the analysis timeframe

Key Inputs and Assumptions

There are four main components of the model are as follows:

- **Technical Potential Calculator** – Customer data from Xcel Energy was converted into site-by-site estimates of CHP potential using a series of relationships between building type and electric and thermal use.
- **Economic Potential Calculator** – For each site, the simple payback period is calculated based on the appropriate CHP system and energy rates for that system size and application. The payback determines the likelihood that a particular system will be installed by the site.
- **Market Acceptance** – The market acceptance factor or propensity to participate and is based on a national survey of potential CHP customers. The sum of the technical potentials multiplied by the market acceptance factors represents the total market potential – or the estimated quantity of CHP that will ultimately enter the market.
- **Long Term Market Penetration Forecast** – Based on the economic potential estimates, the market penetration over a 10-25 year time horizon is estimated using a diffusion model that provides a realistic representation of how the economic potential will enter the market over time.
- **CHP Outputs and Benefits** – Summary and detailed outputs for each forecast/scenario are characterized including cumulative and annual estimates of market penetration, net effect on gas and electricity consumption, customer economic savings, and emissions both at the site and avoided from the electric power grid.

CHPower has several primary inputs necessary in order to run the model. The key inputs are:

1. Electricity Prices (modeled Xcel Energy rates)
2. Natural Gas Prices (EIA)
3. CHP Technical Potential (Xcel Energy customer data)
4. Market Growth Rates (EIA Annual Energy Outlook (AEO 2018) market sector growth rates)

5. CHP Cost and Performance Assumptions (EPRI)
6. Market Acceptance and Bass Diffusion for expected deployments (ICF)

Key Assumptions Made for Xcel Energy Minnesota

Key assumptions for the DIPSERSE model in this analysis for Xcel Energy are provided in Table A-1, with a comparison to assumptions used in the 2014 analysis.

Table A-1
Assumptions Used for 2019 Analysis (compared to 2014)

Model Inputs	2014 Assumptions/Data	2019 Assumptions/Data
Cost/Performance	2014 EPRI National CHP Assessment	2016 DOE Fact Sheets (or 2014 EPRI Assessment)
Federal ITC	10% reduction for capital costs	10% reduction for capital costs
Discount Rate	7 percent	Simple payback calculation – taxes and depreciation are not applied
Depreciation Schedule	10 year straight line	
Tax Percentage	35 percent	
Property Taxes, Insurance	35 percent	
Natural Gas Pricing	2013 average prices – lower of state average industrial price or city gate price plus $1/MMBtu	2018 average prices – lower of state average industrial price or city gate price plus $1/MMBtu
Natural Gas Escalation	Provided by Xcel Energy	Probided by Xcel Energy
Electricity Pricing	Based on Xcel Energy's latest electricity tariff	Based on Xcel Energy's latest electricity tariff
Electricity Escalation	Provided by Xcel Energy	Provided by Xcel Energy
Standby Service	Contract demand charges for secondary (<3,000 kW) and primary (>3,000 kW) service customers	Contract demand charges for secondary (<3,000 kW) and primary (>3,000 kW) service customers
Value of Backup Power	$0	$0
Part-Load Efficiency	Reductions to 50% of peak load, based on load profile following	DG/CHP sized to operate near full-load, switch to standby during low-load periods
DG Maintenance Escalation	2 percent	N/A (not expected to escalate beyond inflation)
Commercial Load Profiles	Generated from DOE2model building simulations and matched to consumer sites	Annual hours of operation applied to average loads, CHP utilization percentage from load shape
Industrial Load Profiles	Weekday/weekend load shapes collected from representative facilities, matched to consumer sizes	Annual hours of operation applied to average loads, CHP utilization percentage from load shape
CO_2 Emission Reductions	Average Xcel Energy emission rates as of 2014 applied throughout 15-year analysis timeframe	Marginal Xcel Energy emission rates, adjusted over the 20-year analysis period based on plans to reduce fossil fuel generation (100% carbon free by 2050)

The Electric Power Research Institute, Inc. (EPRI, www.epri.com) conducts research and development relating to the generation, delivery and use of electricity for the benefit of the public. An independent, nonprofit organization, EPRI brings together its scientists and engineers as well as experts from academia and industry to help address challenges in electricity, including reliability, efficiency, affordability, health, safety and the environment. EPRI also provides technology, policy and economic analyses to drive long-range research and development planning, and supports research in emerging technologies. EPRI members represent 90% of the electricity generated and delivered in the United States with international participation extending to 40 countries. EPRI's principal offices and laboratories are located in Palo Alto, Calif.; Charlotte, N.C.; Knoxville, Tenn.; Dallas, Texas; Lenox, Mass.; and Washington, D.C.
