600 East Boulevard
Bismarck, ND 58505-0480

RE: XCEL ENERGY 2020-2034 UPPER MIDWEST RESOURCE PLAN
CASE NO. PU-19-___

Dear Mr. Kahl:

Pursuant to the provisions of the Settlement approved by the Commission in Case No. PU-07-776, Northern States Power Company, doing business as Xcel Energy, submits eight (8) copies of its 2020-2034 Upper Midwest Resource Plan (Plan) filed with the Minnesota Public Utilities Commission.

We look forward to continued conversations with Commission Staff regarding this Resource Plan and the opportunity to build upon previous discussions to implement a separate, formalized Resource Plan process in North Dakota for the next planning cycle. We also offer to present this 2020-2034 Resource Plan to the Commission at a future Periodic Information Exchange meeting, Informal Hearing, or another venue of the Commission's choice.

Overview

The development of the Company's 2020-2034 Resource Plan is the product of a stakeholder process in Minnesota involving public workshops, an independent expert analysis, and information sharing. The Plan was also designed to support the Company's goal of reducing carbon emissions (in 2005) 80 percent by 2030, and continue progress toward its ultimate vision of 100 percent carbon-free energy by 2050.

At the same time, this Plan ensures the same level of reliability our customers have enjoyed for decades. This is accomplished primarily through the proposed extension of the Company's Monticello nuclear plant by an additional 10 years and the continued operation of the Prairie Island nuclear units through their current license. In addition, Xcel Energy proposes to purchase the 765 MW Mankato Energy Center combined cycle facility, and construct a new natural gas combined cycle plant at our Sherco site in 2026. These large, dispatchable resources will be critical as we retire 2,400 MW of coal-fired baseload in the next decade and transition to a system that is more than 50 percent intermittent renewables. Finally, we also propose several peaking resources but defer these additions until the latter part of the Plan period with the view that resources such as batteries will continue to improve and decline in cost.

The key components of the 2019 IRP include:

- Extend the Monticello nuclear plant license from 2030 to 2040, and operate both Prairie Island units through the end of their current licenses (PI Unit 1 to 2033 and PI Unit 2 to 2034),
- Retire our last two coal units early: the King plant in 2028 (nine years early) and Sherco 3 in 2030 (ten years early);
- Continue our plan to retire Sherco 1 and 2 in 2026 and 2023, respectively, and commit to offering Sherco 2 into MISO on a seasonal basis until its retirement,
- Acquire and operate the 765 MW Mankato Energy Center (MEC) and build, own and operate a 750 MW Sherco Combined Cycle (Sherco CC) to satisfy capacity and operational need created by coal closures,
- Acquire 4,000 MW of utility-scale solar generation between 2025 and 2034,
- Add 1,202 MW of cumulative wind by 2034 as part of a "no going back" strategy, replacing wind scheduled to retire during that period.
- Starting in 2031, add 1,728 MW of cumulative firm dispatchable resources by 2034,
- Include energy efficiency programs representing an average of approximately 780 GWh of savings in Minnesota annually for each year through 2034, in addition to 400 MW of Demand Response by 2023.

With this proposed Plan, Xcel Energy believes it can keep annual cost growth at or below the rate of inflation. This is accomplished by deferring resource additions until later in the plan, making use of existing assets on our system, and through aggressive Demand Side Management activities, mainly in Minnesota. Additionally, the Company foresees that technological improvements will continue to drive the costs of renewables down - a key consideration in the Plan's inclusion of significant solar additions in the latter half of the next decade.

"North Dakota Plan" Assumptions Scenario (Exclusion of Externalities)

As discussed in the Planning Landscape chapter of this 2020-2034 Resource Plan, Xcel Energy plans and operates a single Upper Midwest system (the NSP System) that serves customers in five states. Consistent with the terms of the Settlement in Case No. PU-07-776, since 2008 we have filed our Upper Midwest Resource Plans with the North Dakota Commission, and included in each of them an analysis of a Resource Plan scenario compliant with Federal and North Dakota laws only.

As with the previous 2016-2030 Resource Plan, the current Plan refers to this scenario as simply the "North Dakota Plan". It differs from the Preferred Plan in three ways:

1. All assigned CO_2 costs have been removed;
2. Exclusion of MN Community Solar Garden program costs; and
3. Exclusion of incremental Demand Response program cost.

While there are no renewable energy objectives or policy mandates currently impacting the expansion resources, the Company's long-term objective relative to power generation is to achieve an 80 percent reduction in its 2005 carbon emissions by 2030, and to achieve carbon-free generation by 2050. For the North Dakota Plan scenario, we maintain this goal and propose the same resource additions to our system as reflected in our Preferred Plan.

You will note that in the modeling for the North Dakota Plan, solar additions for 2027-2029 in the Preferred Plan are delayed to 2029 - 2030. The exclusion of the Community Solar Gardens (CSG) do not impact the resources additions for the North Dakota Plan. Instead, the costs of CSG are allocated so that North Dakota customers pay a market rate for the energy from the CSG resources. The allocation of the costs to North Dakota will also reflect previous cost-recovery decisions that exclude costs related to the disputed resources identified in the rate case Settlement of Case No. PU-12-813 and subsequent cases. As discussed previously, our preferred plan also includes a large incremental addition of demand response in recognition of the Minnesota Commission's Order requiring 400 MW of additional DR by 2023. The Present Value of Revenue Requirements (PVRR) over the 2020 – 2034 period for the North Dakota Plan is $37,598,000 while that of the Preferred Plan is $37,851,000.

While modeling a "North Dakota Plan" scenario may provide some additional insight for this Commission, the Company is committed to exploring how we can improve the resource planning process in North Dakota. We proposed in December 2018 a framework outlining some of the essential pieces of a more formal, focused North Dakota resource plan process, including a presumption that the default approach to NSP System planning would continue to be initiated from an integrated system view. Xcel Energy presented the proposal further at an Informal Hearing with the Commission in March of this year. At that time, the Commission indicated interest in exploring a formalized North Dakota process, so the Company looks forward to engaging further to develop such a framework for the next resource planning cycle.

North Dakota Combustion Turbine

Pursuant to the Settlement in Case No. PU-12-813, the Company agreed to take steps to locate a system natural gas combustion turbine (CT) in the state of North Dakota, to be operational by December 31, 2025. Specifically, Xcel Energy agreed to:

"…develop, own, and operate (or alternatively, cause to be developed and operated on its behalf through a power purchase agreement or other contractual arrangement) a combustion turbine with a capacity of at least 200 MW in eastern North Dakota, no later than December 31, 2025. The costs of the generating facility will be allocated to all state jurisdictions served by the Company in a manner consistent with other NSP System resources. Attainment of this commitment is contingent on the Company's receipt of all necessary and appropriate permits and regulatory approvals. Further, except as modified by this Section II, all provisions of the 2036 Commitment remain in place, including without limitation, the requirements that the combustion turbine agreed to in this paragraph reasonably 1) addresses a system capacity need and 2) represents a least-cost resource when also considering the local reliability and system benefits of developing thermal generation in North Dakota."

The 5 year Action Plan within this 2020-2034 Resource Plan runs from 2020 through 2024. Thus, the Commission will not find specific mention of a North Dakota natural gas CT addition in the current short term Action Plan; rather, proposed resource additions in 2025 will be within the Action Plan developed in the next Resource Planning cycle and addressed directly in that filing.

While the longer term plan for resource additions does not reflect a firm peaking plant need until 2031, Xcel Energy acknowledges the Negotiated Agreement commitment and will continue to assess 1) NSP System capacity needs over the next couple of years, 2) the likelihood of gaining the necessary approvals in all NSP System states, and 3) the operational feasibility and cost-effectiveness of a peaking plant located in eastern North Dakota. Given the long planning horizons in these Resource Plans, many

things can change in the next 5 to 10 years in terms of energy policy, technology, and economic conditions. The Company remains committed to locating more generation in the state, and a more timely and beneficial option may become evident over time.

Summary

This plan demonstrates that we can achieve our 2030 environmental goal with existing technologies and resources while maintaining both reliability and affordability. And it advances a framework that achieves our objectives in manageable steps as opposed to transitioning the entire system and grid all at once. By doing so, we can continue to ensure the reliability of our system and maintain flexibility to respond to future market trends, technology advancements, and changing regulatory policies.

Please contact me at (701) 241-8632 or via email at dave.sederquist@xcelenergy.com. Alternatively, you may wish to contact PJ Martin at (612) 321-3065 or Philip.J.Martin@xcelenergy.com if you have any questions regarding this filing.

Sincerely,

David H. Sederquist

RE: 2020-2034 UPPER MIDWEST INTEGRATED RESOURCE PLAN
DOCKET NO. E002/RP-19-368

Dear Mr. Wolf:

Northern States Power Company, doing business as Xcel Energy, is pleased to submit our 2020-2034 Upper Midwest Integrated Resource Plan to the Minnesota Public Utilities Commission. This plan identifies the resources we will need to serve our customers over the next 15 years.

This Resource Plan charts the path toward achieving some of the most ambitious decarbonization goals of any utility in the U.S. Specifically, we aim to reduce carbon emissions from 2005 levels by 80 percent by 2030, and provide 100 percent carbon-free energy by 2050. This Resource Plan sets out our plan to reach the 2030 goal through retirement of our coal fleet, extension of nuclear, aggressive renewable additions and demand-side management including both energy efficiency and demand response, and a mix of load-supporting, firm dispatchable resources. Not only does this Resource Plan achieve these goals, it does so reliably and affordably.

We look forward to discussing this Resource Plan with the Commission, stakeholders, and the community.

Request for Protection of Trade Secret Information

The Company recognizes and supports the need for transparency in review of our Resource Plan. We also take seriously our responsibility to maintain the security of

the information and systems involved in the delivery of safe, reliable energy to our customers.

Appendix J3: Y2 Study: King & Sherco Unit 3 Coal
Attachment J3 is marked as "Non-Public" in its entirety and is provided with Critical Energy Infrastructure Information (CEII) redacted. Attachment J3 contains information regarding the MISO area grid, including specific information about the Xcel Energy and other transmission owner systems as it relates to the potential retirement of Xcel Energy's Allen S. King and Sherburne County Generating Plant (Sherco) Unit 3. While MISO has redacted all CEII from the report, Xcel Energy maintains that the balance of the information is "security information" as defined by Minn. Stat. § 13.37, subd. 1(a).

Pursuant to Minn. R. 7829.0500, subp. 3, the Company provides the following description of the excised material:

1. **Nature of the Material**: Prepared study.
2. **Authors:** The study was prepared by MISO.
3. **Importance:** The study contains security information.
4. **Date the Information was Prepared**: The study was finalized November 14, 2018

Appendix J4: Y2 Study: Monticello, Prairie Island, & All Coal & Nuclear
Attachment J4 is marked as "Non-Public" in its entirety and contains redactions to CEII for the same reasons noted for Attachment J3. Xcel Energy maintains that the balance of the information is "security information" as defined by Minn. Stat. § 13.37, subd. 1(a).

Pursuant to Minn. R. 7829.0500, subp. 3, the Company provides the following description of the excised material:

1. **Nature of the Material**: Prepared study.
2. **Authors:** The study was prepared by MISO.
3. **Importance:** The study contains security information.
4. **Date the Information was Prepared**: The study was finalized November 27, 2018

Appendix N1: NSP 2013 Annual Electric Utility Forecast Report
Certain portions of Appendix N1 are marked as "Non-Public" as it contains private data on individual customers, including names, addresses, and energy usage data for our largest electric customers. This information is maintained by the Company as "nonpublic data" and "private data on individuals" pursuant to Minn. Stat. §§ 13.02 and 13.03. This report also contains forecast data of annual system consumption and generation. This information is trade secret information as defined by Minn. Stat. §13.37(1)(b). This information derives independent economic value from not being generally known or readily ascertainable by others who could obtain a financial advantage from its use.

Appendix N3: 10-Year Plan: South Dakota
Certain portions of Appendix N3 have been designated as Trade Secret information pursuant to Minnesota Statute § 13.37, subd. 1(b). In particular, the information includes confidential pricing and other contract terms, as well as confidential forecast data. The information designated as Trade Secret derives independent economic value, actual or potential, from not being generally known to, and not being readily ascertainable by proper means by, other persons who can obtain economic value from its disclosure or use.

Appendix N5: Biennial Report: Renewable Energy Obligation-Renewable Energy Standard Compliance Report
Certain portions of Appendix N5 have been designated as Trade Secret information pursuant to Minnesota Statute § 13.37, subd. 1(b). In particular, this report contains forecast data of annual system consumption and generation. The information designated as Trade Secret derives independent economic value, actual or potential, from not being generally known to, and not being readily ascertainable by proper means by, other persons who can obtain economic value from its disclosure or use.

Appendix N7: Annual Report: Solar Energy Standard
Certain portions of Appendix N7 contain information we have marked as "Non-Public" including information identifying customer names, locations, energy usage or bill credits. This information is maintained by the Company as "nonpublic data" and "private data on individuals" pursuant to Minn. Stat. §§ 13.02 and 13.03.
We have also marked as "Non-Public" capacity factor information relating to specific Purchase Power Agreements (PPAs). The terms of the Commission approved PPAs require that this information be non-public. Further, this is considered to be "nonpublic data" pursuant to Minn. Stat. §13.02, Subd.9, and is

also "Trade Secret" information pursuant to Minn. Stat. §13.37, subd. 1(b) as it derives independent economic value, actual or potential, from not being generally known to, and not being readily ascertainable by proper means by other persons who can obtain economic value from its disclosure or use.

Appendix R: Study: Interconnection Cost Estimates-CC (Excel Engineering)
Appendix R is marked as "Not Public" in its entirety as it includes information the Company considers to be trade secret data as defined by Minn. Stat. § 13.37(1)(b). As set forth below, the information designated as Trade Secret derives independent economic value, actual or potential, from not being generally known to, and not being readily ascertainable by proper means by, other persons who can obtain economic value from its disclosure or use.

Pursuant to Minn. R. 7829.0500, subp. 3, the Company provides the following description of the excised material:

1. **Nature of the Material**: Prepared study.
2. **Authors:** The study was prepared by Excel Engineering.
3. **Importance:** The study contains competitively sensitive data related to project costs.
4. **Date the Information was Prepared**: The study was prepared during the fourth quarter of 2018.

Copies of the filing have been served on Commission staff, the Department of Commerce, and the Office of the Attorney General – Residential Utilities Division. We have also provided a copy to the Minnesota Environmental Quality Board. Interested parties will be able to obtain copies from our web site at xcelenergy.com/UpperMidwestEnergyPlan

Please contact Bria Shea at (612) 330-6064 or bria.e.shea@xcelenergy.com if you have any questions regarding this filing.

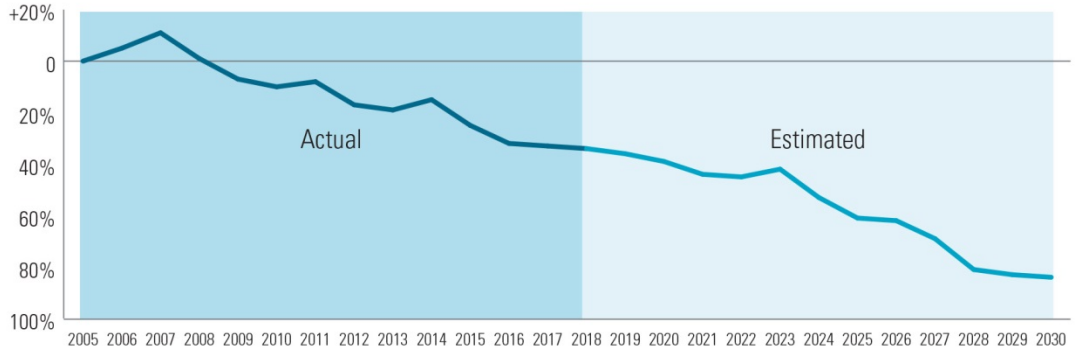
2020-2034 UPPER MIDWEST INTEGRATED RESOURCE PLAN

CHAPTER 1
EXECUTIVE SUMMARY

I. INTRODUCTION

This 2020-2034 Upper Midwest Integrated Resource Plan charts the path toward achieving some of the most ambitious carbon reduction goals of any utility in the U.S. Specifically – we aim to reduce carbon emissions 80 percent by 2030, and provide 100 percent carbon-free energy by 2050. This Resource Plan not only reaches the 2030 goal through retirement of our coal fleet, extension of nuclear, aggressive renewable additions, and demand-side management including both energy efficiency (EE) and demand response (DR), and a mix of load supporting, firm dispatchable resources – it embraces technology and innovation and is well-grounded in reliability and affordability. And while the last stretch of total carbon reduction – from 80 to 100 percent – will require technologies that have not yet been developed or deployed economically, we are confident that we can work with regulators, policymakers, and stakeholders to position ourselves so we are prepared to take advantage of the cost-effective solutions that emerge over the course of the next 30 years.

Figure 1-1: Projected Carbon Emissions Through 2030



Our Preferred Plan is the product of an unprecedented stakeholder process that included 13 public workshops, independent expert analysis, and months of information sharing as we developed a Preferred Plan. As a result of those efforts, our Preferred Plan is the product of an unusual amount of consensus this early in the Resource Plan process. That consensus is represented by an agreement signed by the Company, the Clean Energy Organizations,[1] Center for Energy and Environment,

[1] The Clean Energy Organizations include Clean Grid Alliance, Minnesota Center for Environmental Advocacy, Fresh Energy, and Union of Concerned Scientists.

Sierra Club, and LIUNA Minnesota and North Dakota that resolves (among those parties) many of fundamental building blocks of our plan.

Those building blocks include the elimination of coal-fired generation from our system by 2030, as well as the reduced, seasonal dispatch of Sherco 2 until its retirement in 2023. The agreement also includes the acquisition of at least 3,000 megawatts (MW) of utility-scale solar by 2030, and a substantial increase in EE programs, representing an average annual savings of over 780 gigawatt hours (GWh). Finally, the agreement includes support for the Company's proposal to take ownership of the Mankato Energy Center (MEC) combined cycle (CC), which will be central to our reliability strategy as we retire 2,400 MW of coal and integrate several gigawatts (GW) of new renewable resources. The Company's Preferred Plan builds upon this agreement and adds proposals to operate our carbon-free Monticello nuclear plant for an additional 10 years beyond its current license, add a significant amount of DR resources, and construct a new CC at our Sherco site. In total, we have an ambitious plan that supports the Company's goal of reducing carbon emissions 80 percent by 2030, and it moves us toward our ultimate vision of 100 percent carbon-free energy by 2050.

Figure 1-2: Preferred Plan Highlights

Close coal plants
Retire the last of our coal plants in the Upper Midwest by 2030, a decade earlier than planned

Add renewables
Add at least 3,000 megawatts of solar by 2030, enough to power more than 650,000 homes each year, and complete our largest-ever wind expansion by 2022

Continue carbon-free nuclear
Start the process to gain regulatory approval to run our carbon-free Monticello nuclear plant until at least 2040

Bridge to carbon-free
Use natural gas-fired plants in the coming years as a reliable, cleaner source of electricity as we bridge toward future carbon-free technologies

Throughout this process, we have taken steps to ensure that we can meet these progressive carbon reduction goals while preserving the reliability our customers have enjoyed for decades. To that end, the Company's engineering and operations teams have conducted extensive analyses to ensure that we can continue to serve customers

every hour of every day, even as we progress toward relying on intermittent resources for a majority of our generation. In this work, we have aimed to embrace change while addressing the physical realities of our system and the responsibility that comes with providing a genuinely essential service.

The addition of several gigawatts of renewable resources requires that we consider not only our traditional summer peak, but also whether we have sufficient dispatchable resources to meet other peaks, including in winter when solar energy is typically unavailable and wind resources may not be available for long periods of time. Our Preferred Plan addresses these reliability issues in three ways. First, the extension of Monticello by an additional 10 years and the continued operation of Prairie Island will anchor our grid in around-the-clock, carbon-free energy. Second, we are proposing to take ownership of the Mankato Energy Center and build a new CC plant at our Sherco site in 2026. These dispatchable resources will be critical as we retire 2,400 MW of coal-fired baseload and transition to a system that is nearly 60 percent renewable and intermittent generation. Finally, we propose several firm dispatchable, load-supporting resources – but defer these additions until the latter part of the decade, in anticipation of technological advancements that will improve the functionality and drive down the cost of resources, like storage, that can take the place of traditional gas peaking units.

We also recognize that the achievement of our carbon reduction goals will depend on our ability to keep rates affordable. We believe that our Preferred Plan accomplishes this by keeping annual cost growth below the rate of inflation. The modest cost of our plan is facilitated by our strategy of deferring resource additions until later in the plan and making use of existing assets on our system. Additionally, we believe technological improvements will continue to drive the costs of renewables down, which is a key element in our strategy of proposing significant solar additions in the latter half of the next decade.

We also know that our proposed plan includes impacts both on the communities we serve and our employees. We appreciate not only the challenge – but the stakes for those impacted – and we plan to build on our successful track record of working with our communities, policymakers, stakeholders and employees to successfully manage this clean energy transition.

We further recognize that the agreement underlying our Preferred Plan is simply the beginning of a process. And although elements of our Preferred Plan are captured by the Settlement, the parties to the agreement have not endorsed the entire plan and the Commission has not yet approved the plan. As a result, we look forward to a healthy discussion on the best way forward. That said, we view the agreement – which

promises the elimination of coal and the new prominence of solar on our system – as a great foundation from which to work. We believe both the process and outcome of this collaborative effort are a testament to the regulatory landscape in the states we serve, and we look forward to continuing the discussion around this transformational plan and our collective energy future.

II. EXECUTIVE SUMMARY

In our last Resource Plan (Docket No. E002/RP-15-21), we discussed the rapid evolution of our industry due to changing technology, enhanced customer expectations, and the increasing consensus around the importance of carbon reduction. We also noted that partnership among our stakeholders, communities, and the Company would become even more important to navigating these changes. In approving our prior plan, the Commission likewise noted that resource planning is a collaborative and iterative process and that a full understanding of the relevant facts requires exposure to the views of engaged and knowledgeable stakeholders.

We are filing this 2020-2034 Upper Midwest Integrated Resource Plan following an unprecedented stakeholder process that included 13 public workshops with topics from the evolving resource planning process, to more technical considerations, such as transmission and system reliability. We also engaged a third-party consultant—Energy and Environmental Economics, Inc. (E3) to conduct independent, parallel analysis to inform the Company's future resource strategy. E3 presented its findings to a diverse group of stakeholders at a workshop in April 2019. We then presented our own preliminary Preferred Plan at our final stakeholder workshop in May 2019.

We believe this combination of a significant internal effort, extensive collaboration, independent expert analysis, and transparency has improved not only the process that led to the development of our Preferred Plan but also the plan itself. In fact, it was through this stakeholder engagement that the Company, the Clean Energy Organizations,[2] Center for Energy and Environment, Sierra Club, and LIUNA Minnesota and North Dakota were able to reach an agreement that addressed many of the cornerstones of our Preferred Plan, including: (1) retirement of our last two coal units by 2030; (2) seasonal dispatch of Sherco 2 until its retirement in 2023; (2) acquisition of the MEC CC; (3) acquisition of at least 3,000 MW of utility-scale solar by 2030; and (4) a substantial EE goal.

We acknowledge that this agreement is just the start of the process – a process that

[2] The Clean Energy Organizations include Clean Grid Alliance, Minnesota Center for Environmental Advocacy, Fresh Energy, and Union of Concerned Scientists.

began with the Commission and its request to conduct a holistic review of our baseload resources. As we return to the Commission and begin to engage with the Commission directly in this Integrated Resource Plan docket, we look forward to the opportunity to demonstrate the substantial benefits of our Preferred Plan. It is also true that the terms of the agreement outlined above do not cover all components of our Preferred Plan, and we recognize that stakeholders continue to have wide-ranging perspectives on our collective energy future. We welcome those perspectives as part of this process, and we look forward to more collaboration and iteration as this docket moves forward. That said, we view the agreement as a very good start and a positive outcome from our stakeholder process; we appreciate the Commission setting us on the path; and, we believe the agreement demonstrates that stakeholders and the Company can find common ground and build consensus around key building blocks of a plan that satisfies the needs of our five-state Upper Midwest region – and meets individual state goals as well. Indeed, meeting the varied interests of our integrated system was an important foundation of our planning process.

Both the agreement and our overall Preferred Plan are consistent with the Company's environmental goals. For more than a decade, Xcel Energy has been a leading wind energy provider in the nation and has pursued a successful strategy to transition to clean energy. We have surpassed both national and international goals, including the U.S. commitment under the Paris Climate Accord of 26-28 percent reduction in carbon emissions by 2025. To-date, we have reduced carbon emissions 38 percent companywide from 2005 levels. We are proud of these achievements and grateful to our many stakeholders who have played a role in our journey.

In December 2018, the Company expanded on its commitment to clean energy by announcing industry-leading goals to reduce carbon emissions 80 percent Company-wide by 2030,[3] and to provide 100 percent carbon-free electricity across our service territory by 2050. This 2020-2034 Upper Midwest Integrated Resource Plan charts a path to accomplishing these goals through the elimination of all coal generation on our system by 2030, the addition of over 5,000 MW of renewables, and the expansion of our industry leading EE and DR programs. It accomplishes these environmental milestones while not sacrificing operational reliability or affordability. Specifically, we propose to do the following:

- ***Coal Resources -*** Retire our last two units early: King in 2028 (nine years early) and Sherco 3 in 2030 (ten years early). Additionally, continue our plan to retire Sherco 1 and 2 in 2026 and 2023, respectively, and commit to offering Sherco Unit 2 into Midcontinent Independent System Operator (MISO) on a seasonal basis until its retirement.

[3] From 2005 levels.

- ***Nuclear Resources-*** Operate our Monticello unit through 2040 (10 years longer than its current license) and operate both Prairie Island units through the end of their current licenses (PI Unit 1 to 2033 and PI Unit 2 to 2034).[4]
- ***Renewable Resources –*** While the exact wind and solar mix could vary based on a variety of reasons, at this time we propose to add 4,000 MW of cumulative utility scale resources by 2034 (the first being in 2025) and approximately 1,200 MW of cumulative wind by 2034 to replace wind that is set to retire from our system during that period.
- ***Combined Cycle Resources –*** Acquire and operate MEC and build, own and operate the Sherco CC to satisfy significant capacity and operational need created by coal closures.
- ***Firm Load Supporting Resources –*** Starting in 2031, add approximately 1,700 MW of cumulative firm dispatchable, load-supporting resources by 2034.
- ***Demand Side Management (DSM) -*** Include EE programs representing approximately 780 GWh of savings annually through 2034 (compared to average annual energy savings of 444 GWh in our last Resource Plan) and the addition of 400 MW of incremental DR by 2023 with a total of over 1,500 MW DR by 2034.

This plan demonstrates that we can achieve our 2030 goal with existing technologies and resources while maintaining both reliability and affordability.[5] However, it also creates opportunities to introduce emerging technologies as part of the solution. We see opportunities for innovation in our ongoing EE and DR programs. Likewise, we believe the industry will deliver new and improved technologies that will support our long-term need for firm, load supporting resources. The plan also advances a framework that achieves these goals in manageable steps as opposed to transitioning the entire system and grid all at once. By doing so, we can continue to ensure the reliability of our system and maintain flexibility to respond to future market trends, technology advancements, and changing regulatory policies
Below, we discuss our proposed resource mix further, as well as the priorities and considerations that drove the development of our plan.

[4] Given that our operating licenses for Prairie Island run until 2033 and 2034, we believe there is sufficient time to address the future of that plant in upcoming resource plans.
[5] As we explained our December 2018 announcement, we recognize that serving customers with 100 percent carbon-free electricity will likely require technologies not yet commercial available, and we look forward to discussing these technological developments in future resource plans.

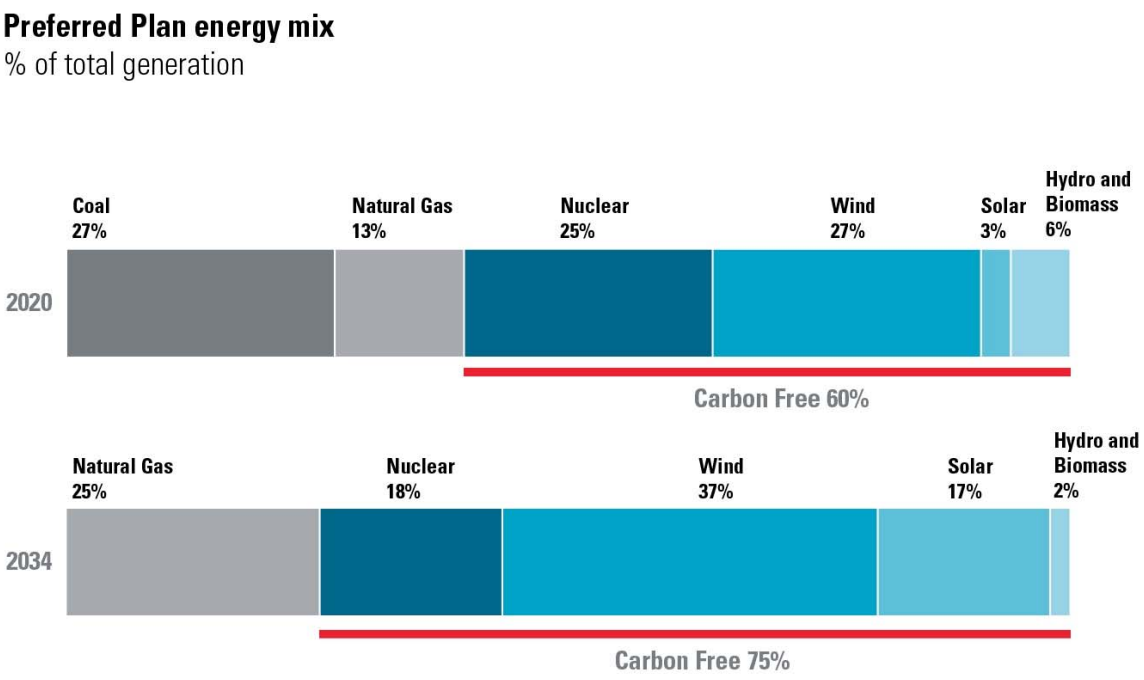
A. Proposed Resource Mix

Our Preferred Plan reflects a significant transformation of our resources. We have more than 1,300 MW of energy resources subject to power purchase contracts that are expiring. Our plan is also informed by an extensive study of all of our baseload resources, completed in response to the Commission's last Resource Plan Order. That study included seven Attachment Y2 studies by MISO and a more traditional NERC-based analysis of our fleet by an external consultant. All of these potential retirements were then studied in conjunction with the addition of significant renewable resources needed to meet our 80-by-30 goal, which identified reliability and stability issues that will need to be resolved as we move through the planning period.

As a result of this work, our Preferred Plan takes a measured approach to adding and retiring resources, and it prioritizes reliability and long-term system planning – as it must. In the first five years, we have no incremental capacity needs and propose only minimal additions.[6] In fact, there are no significant resource additions until 2025 when our first utility-scale solar is proposed. By relying on our existing resources in the near term, we preserve flexibility to respond to changing customer needs and regulatory policies, and we can monitor technological change to ensure we make future resource investments at the speed of value when they are in the best interest of our customers. We will continue our aggressive support of EE and DR and are looking to emerging resources to be part of that solution.

[6] Our actions in the next five years will address previously approved or pending resource additions and retirements, wind repowering and procurement to meet specific customer or program needs, community solar garden growth, and DSM programs.

Figure 1-3: Preferred Plan Energy Mix through 2034



That said, in light of the potential baseload retirements and expiring power contracts, we must address nearly 75 percent of the energy-producing resources on the NSP System during the 15-year planning horizon. We developed the Preferred Plan with an eye toward maximizing cost-effective renewable resources, backed by natural gas to support renewable integration and system reliability, in an effort to minimize market and commodity exposure. By doing so, our system will not be overly reliant on any one fuel source, and we will retain our trademark reliability – along with the flexibility to consider the economics of new resources as our baseload plants retire.

We discuss the components of our proposed resource mix in greater detail below.

1. Coal

With respect to coal-fired generation, our 2020-2034 Resource Plan represents a monumental step forward in transitioning our fleet. Today, as a result of our agreement with the Clean Energy Organizations, Center for Energy and Environment, Sierra Club, and LIUNA, we are proposing to retire our King plant in 2028 and Sherco 3 in 2030 – meaning that Xcel Energy will complete its transition away from coal-fired generation in 2030 – a full decade earlier than previously anticipated. In total, we plan retire approximately 2,400 MW of coal-fired generation in the next decade.

The early retirement of these plants allows us to reduce and ultimately eliminate our reliance on coal, enable additional cost-effective renewable resources, and save customers money. In addition to these retirements and the early retirements of Sherco Units 1 and 2 approved in our 2015 Resource Plan, we are also proposing to offer Sherco Unit 2 into MISO on a seasonal basis until its retirement in 2023, which we expect will reduce its carbon emissions in the near term.

This accelerated transition away from coal requires the Company to plan for the retirement of 2,400 MW of coal-fired generation in the next decade, which represents almost one-fourth of the total capacity in our current generation fleet. This will be an unprecedented period of transition for our system that necessitates a prudent replacement strategy. Our strategy for replacing these MWs includes a combination of natural gas CC resources, continued reliance on nuclear generation, large renewable additions during the planning period, and a continued commitment to both EE and DR, all of which will be critical to maintaining reliability throughout this baseload transition. We discuss each in turn below.

2. Nuclear

Carbon-free nuclear generation has been a cornerstone of our generation fleet for nearly half a century. Today, our nuclear plants generate about half the carbon-free energy for our Upper Midwest customers – amounting to the avoidance of about 7 million metric tons of carbon dioxide annually. This is equivalent to removing 1.5 million cars from the road. Our nuclear fleet is therefore critical to meeting our "80-by-30" goal and maintaining that level into the future.

Our nuclear units enable the Company to achieve and maintain our carbon reduction goals while incorporating incremental renewables at a reasonable pace and maintaining reliability. Nuclear is also an important system resource during the winter months, as it does not experience fuel supply issues and has a great track record during cold weather events – making it a critical piece of our reliability strategy, which we discuss below.

In light of these considerations and others discussed later in this filing, our Preferred Plan includes operating our Monticello nuclear plant until 2040, along with the continued operation of Prairie Island through its current operating licenses (which expire outside the planning period of this Resource Plan, in 2033 and 2034). By continuing the operation of these plants and extending our Monticello license, we can continue to enjoy the substantial carbon-free benefits these baseload units provide while saving our customers money by leveraging existing assets on our system.

Absent a Monticello operating extension, based on the reliability needs of the system, any suitable replacement resource would add carbon to our portfolio. We simply could not maintain our system reliably, or affordably, given the massive renewable additions and corresponding transmission infrastructure that would be required to replace our Monticello nuclear plant, if it were even possible by 2030, given MISO's current transmission expansion issues.

The recommendation to extend the Monticello unit is supported by its operational performance, which has achieved an average capacity factor of 96.5 percent over the past three years (including a record-setting 99.3 percent in 2018). Moreover, we achieved this performance all while reducing production costs by more than 20 percent since 2015. We believe this performance demonstrates that we can achieve deep carbon reduction along with industry-leading safety and reliability at an affordable cost. For all of these reasons, our nuclear strategy is sound and is in our customers' best interest and consistent with the public interest.

Procedurally, we intend to bring a petition for a Certificate of Need (CON) to address the Monticello license extension request to the Commission in the coming years. In that filing, we will provide detailed capital budgets and O&M forecasts, as well as economic modeling to justify our request. Given that the Prairie Island Units' licenses do not expire until 2033 and 2034, we believe we have time to address the future of these units in our next Resource Plan. We look forward to engaging with the Prairie Island Indian Community, Monticello, and Red Wing as we begin a discussion about the role of nuclear in our energy future.

3. Renewable Resources

Substantial renewable additions are a central component of our energy future and thus a cornerstone of this Preferred Plan – which proposes to add 4,000 MW of cost-effective, utility-scale solar generation and approximately 1,200 MW of cumulative wind resource additions. While the exact mix of wind and solar added to our system may vary (in concert with a variety of factors including technology advancements and price changes), our commitment to renewable energy will not.

In total, our Preferred Plan envisions a system that is approximately 60 percent renewable energy – a level that puts us among those leading the nation. And, while we are confident in our ability to deliver on our reliability commitment at this high level of renewable penetration, we are somewhat cautious at the same time about going much beyond those levels in light of our own experience, as well as recent industry studies regarding the complexity and complications of an exceedingly high

renewable grid.[7] That said, some of our customers and municipalities have environmental goals that include the achievement of 100 percent renewable energy to meet their needs, and we are confident we can meet those needs given the substantial renewable additions proposed in this Resource Plan.

The capacity value of renewables combines with our cost-effective gas and nuclear generation to deliver safe and reliable service that will withstand the summer and winter peaks of the Upper Midwest. Significantly, with these additions, there would be enough solar generation to power more than 650,000 homes each year.

Wind generation also continues to play a prominent role in this Resource Plan. Xcel Energy has long been one of the nation's leading providers of wind energy, and we are currently engaged in the largest build-out of new wind resources in our Company's history – thanks in large part to the Commission's approval of our last Resource Plan and our 1,850 MW wind portfolio. By 2024, wind will provide approximately 35 percent of the electricity for our customers in this region, making it the largest component of our overall generation portfolio.

4. Combined Cycle Resources

In addition to our carbon-free nuclear baseload resources, the continuation of dispatchable generation on our system will be vital to our ability to manage the retirement of approximately 2,400 MW of coal-fired generation over the next decade while maintaining reliability. It will also facilitate our ability to successfully integrate large amounts of renewables; we can ramp the output of these resources up or down in response to our system's changing needs throughout the day, as renewable resources generate more or less energy due to their variable nature. Finally, dispatchable generation will also help us plan for the expected marginal decline in load carrying capability from renewables as their penetration increases, which we believe could result in additional capacity needs.

To that end, our Preferred Plan includes our acquisition of MEC (a 760 MW two-unit CC), as proposed in Docket No. IP6949,E002/PA-18-702,[8] as well as our plan to build the approximately 800 MW Sherco CC located in Becker, Minnesota in the mid-2020s. As discussed in the pending MEC docket, that plant is already an integral part of our system, as its output is committed to the Company through two Commission-approved PPAs. By securing ownership of the plant, we can mitigate the risk

[7] *See* https://twin-cities.umn.edu/news-events/research-brief-planning-future-energy-demand-renewable-energy and MISO's *Renewable Integration Impact Assessment* (RIIA), which we discuss in Appendix J2: Reliability Requirement.
[8] We will incorporate any Commission decision from that docket into our modeling and supplement the record as necessary.

associated with expiration of the first PPA in 2026, thereby achieving additional certainty with respect to capacity and dispatchable energy.

As discussed in our last Resource Plan, we propose to locate a CC at the existing Sherco site because it will allow us to cost-effectively address significant transmission issues identified by the MISO Attachment Y2 study, ensure the stability and reliability of the transmission system, mitigate impacts to the local community and our employees, and potentially provide improved access to natural gas supplies for communities in Central Minnesota.

Together, our MEC acquisition and constructing the Sherco CC will not materially impact the amount of gas generation on our system. As already discussed, MEC is already an existing resource on our system, and the Sherco CC will primarily offset the retirement of other gas generation on our system, including the Cottage Grove facility (approximately 250 MW in 2027) and Black Dog 5 (approximately 300 MW in 2032). This additional gas generation is not only reasonable, but an operational necessity in light of the much larger coal retirements planned – and the large amounts of variable renewable additions we anticipate in the same period.

5. Load Supporting Resources

Reliability is the bedrock of any resource plan. We are particularly focused on the reliability of our system in this plan, however, as we plan for such a large turnover of our baseload fleet and transition to a portfolio that is approximately 60 percent renewable and intermittent generation. We recognize that our transition to cleaner energy will only be successful if we can execute our vision without disrupting our customers' lives and businesses, so we are steadfastly committed to maintaining our performance when it comes to this core tenant of our business.

Based on the results of extensive reliability studies that we discuss further below, we are proposing approximately 1,700 MW of cumulative additions of firm dispatchable, load supporting resources from 2031-2034. The need for these dispatchable resources emerges in this later timeframe due to the major plant retirements already discussed, as well as the expiration of several PPAs. Our reliability analysis demonstrates that these additions are necessary to continue to support grid reliability and resiliency in light of the increased renewables being added to the system and the baseload units being retired. That said, because these units are not needed until the out years of our current plan, we have not identified a specific resource type to meet this need. However, with the expected price declines and technology development, between now and the 2030s, we fully expect utility-scale storage will be an integral resource used to meet this need. Likewise, we believe the deployment of advanced

grid investments could position DR to better compete with traditional generation to fill some of this firm dispatchable need. We are committed to pursuing all of these options not only in the longer term, but in the near term as well in order to position ourselves to leverage this technology as it matures.

In addition, as discussed in our last Resource Plan, system retirements will impact our current blackstart plans and we are currently analyzing our blackstart path to determine the best fit for our system needs. While we do not propose any action related to the system blackstart at this time, we anticipate addressing this in our next Resource Plan or earlier, if system needs dictate the need to do so.

By keeping options open and remaining technology agnostic, we can acknowledge the need for a firm resource at the tail end of our plan but allow the market to advance as we file future resource plans and continue to collaborate with our stakeholders and the Commission as the need for these resources begins to materialize.

In the meantime, we are analyzing potential locations and sizing of storage solutions as well as the potential values storage assets might provide to the system.

6. Energy Efficiency

Our Preferred Plan also proposes to add significant amounts of EE based on the December 2018 *Minnesota Energy Efficiency Potential Study: 2020-2029*. In fact, our proposal includes an annual average of over 780 GWh of savings for 2020-2034. Our last Resource Plan included 1.5 percent annual EE savings assumption, but our current proposal achieves much higher levels of savings – ranging from approximately 2 to 2.5 percent annually. Relative to a 1.5 percent assumed savings level, our proposal achieves more than 200 MW of additional demand savings by 2023, and more than 800 MW by 2034.

7. Demand Response

Finally, consistent with the Commission's Order in our last Resource Plan, our Preferred Plan proposes to add 400 MW of incremental DR by 2023 (with a total of over 1,500 MW of DR by 2034). When it comes to DR, the Company leads the way in MISO, with 830 MW registered in the current planning year. In the last Resource Plan, the Commission ordered the addition of 400 MW of incremental DR by 2023. As we understood the Commission's reasoning, it sought to add incremental, cost effective DR to avoid near-term reliance on additional combustion turbines. As can be seen in our analysis, however, no combustion turbines or other firm, dispatchable resource additions are required until the 2031 timeframe as the model instead prefers

solar additions as the most attractive resource in the 2025-2030 timeframe.

That said, we decided to include the DR in our Preferred Plan for several reasons: (1) to be consistent with the Commission's Order in our last Resource Plan, (2) to fill gaps if/when the solar capacity credit declines, (3) to help meet firm dispatchable resource needs in the 2030s, (4) to help support customer programs, and (5) to integrate new and emerging technology and tools. We note that for purposes of our modeling, we have included all of the DR identified in the Brattle study as cost-effective, including expansions to conventional DR programs (i.e., Savers Switch, smart thermostats, and interruptible rates) and a non-conventional smart electric water heater program. Additionally, we included the addition of Auto DR, another non-conventional DR program that automates control of various end-uses like HVAC and lighting. We believe the advancement of our grid and technology generally may take the form of less traditional DR, so we are requesting the flexibility to evaluate and pursue the required incremental DR through a variety of means and technologies over the coming years.

In this filing, our objective is to bring forward information on all of the viable options so the Commission, stakeholders, and the Company can engage in an informed exchange.

B. Plan Priorities

1. Reliability

The foundation of our business is providing safe and reliable electric service, and the purpose of a Resource Plan is to identify the appropriate resources to continue providing that service to our customers. Building on the reliability and stability issues identified as part of our Baseload Study and renewable integration work, and recognizing that many other utilities within the MISO planning area are also planning to retire their baseload units, we made reliability and resilience a primary consideration of this Resource Plan.

To that end, we have conducted a detailed analysis of what resources will be necessary over the full planning period – once many of our baseload units are retired and the renewable resources have taken their place as our primary source of generation. As part of that work, we have paid increased attention to analyses around our winter peak, when solar is diminished and wind facilities can also drop off as a result of extreme temperatures. That analysis points to a baseline operational level of firm resources needed to continue to support a reliable and resilient grid at all hours of the day, on all days of the year. This operational guidance was then used in our modeling

tool, Strategist, to inform the resource decisions and ensure that all resource mixes we considered would be operationally feasible and reliable to meet our ongoing need to serve our customers. Below, we summarize how we determined the appropriate operational requirement.

Within a large pool of generation resources and an established wholesale energy market like MISO, there is a tendency for market members to project reliance on market resources based on the size of that pool, rather than the specific performance of those resources and the capabilities of the overall system to deliver additional resources. As we move further into a future that relies less on centralized and dispatchable generation resources, these operational considerations around system and resource capabilities become exponentially more important. In other words, as renewable penetration increases throughout the MISO footprint, it becomes increasingly important to consider the variable nature of these resources and their effect on the overall pool when considering reliability and market reliance. Thus, while we can, and do, still rely on the market, that reliance should be tempered during extreme events, because the nature of these events is such that they tend to impact a geographical footprint that is broader than a single plant or transmission line outage. While MISO is working to address these transmission needs, there is a clear need for more collaboration to enable transmission capability to help support the market's ability to facilitate carbon-free objectives going forward.

Due to the variability of renewable generation, the current generation fleet encounters times in which Net Load (defined as the difference between gross demand and renewable generation supply at a given point in time) is near, or even equal to, the gross demand on the system. This is evident in extreme cases, such as the 2019 polar vortex (when MISO used an average of 6,500 MW resource "reserves[9]" to remain operational), but also during normal winter operations like February 5, 2019, which was representative of conditions we typically experience throughout the winter season. For instance, on February 5th, the system encountered 16 hours of demand greater than 5,500 MW (60 percent of annual peak demand). During this same time, the Net Load was above 5,400 MW, with wind and solar together producing only 6 percent of their installed nameplate capacity (dipping at certain hours to 3 percent). Another example, on July 29, 2018, the entire MISO wind portfolio (over 17,000 MW at that time) had a combined output of minus 11 MW – meaning the wind turbines that were online, were taking more power than they were producing. This hour was part of an approximately 110 hour sustained stretch in which the combined output of all wind resources in the MISO footprint fell well below the accredited values used in

[9] These reserves consisted of non-firm resources offered by neighboring regional transmission organizations into the MISO market

present planning processes.

This real-world experience reveals several operational truths:

- First, variable resources cannot meet demand in all hours of the year; firm dispatchable resources are necessary.
- Second, simply increasing the level of renewables on the system cannot address resource shortfalls. With an increased level of renewables, we see some improved ability to meet demand but still encounter several hours in which the net load is very close to the gross load. In fact, the amount of additional renewable generation that would be required to meet customer demand in the above scenarios and without other resources could be in excess of 180,000 MW.
- Third, our ability to rely on the MISO market during winter peaking events is limited by periods of extremely low renewable generation across the MISO footprint and a shortfall of these resources compared to their accredited capacity.
- Finally, the current state of battery storage technology does not have the ability to match the duration of such events without significant (and very expensive) over-build of those resources, and DSM programs also lack the scale to significantly impact the analysis.

In light of these issues, we have determined that sufficient firm, dispatchable resources are required to meet the approximate 6,400 MW winter peak load obligation, and we have imposed this requirement in our Strategist modeling as part of this Resource Plan. Figure 4 below demonstrates the calculation of the firm resources used meet this need.

Figure 1-4: NSP System Reliability Requirement Calculation

Peak Demand Proxy	6,400 MW
Firm Demand Response Proxy	-200 MW
Firm Market Supply Proxy	-500 MW
Reliability Requirement (Firm Dispatchable Resources)	5,700 MW

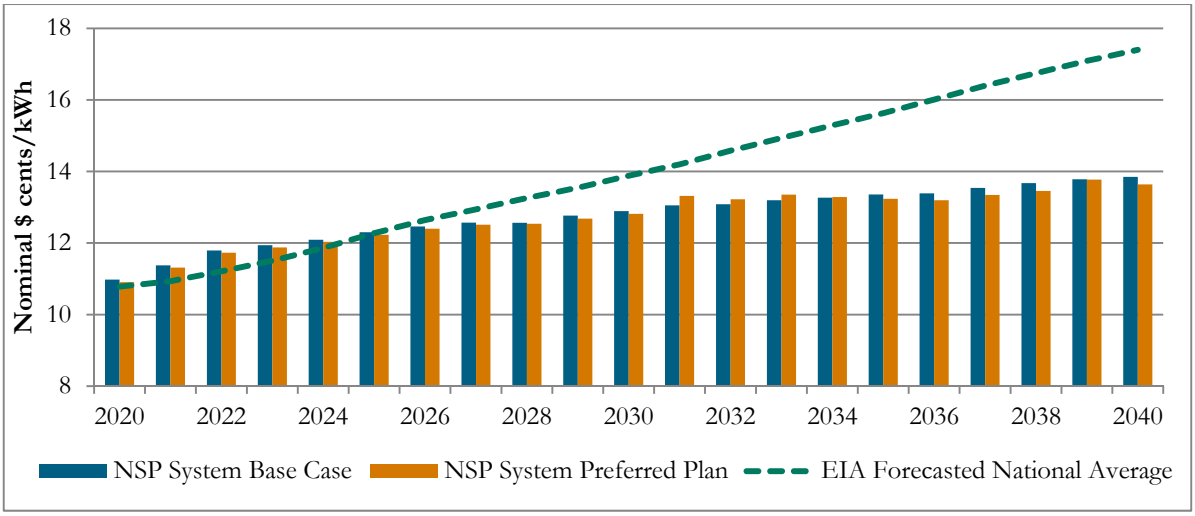
Our analysis shows that these resources will help us match the net load gaps discussed above by ensuring that we maintain a stable and reliable energy system for customers,

while moving through our baseload transition and achieving our nation-leading carbon goals. We discuss our reliability and operational analysis in greater detail later in this filing.

2. *Affordability*

Another priority for Xcel Energy, and our Resource Plan, is energy affordability. Currently, the average monthly Minnesota Xcel Energy residential customer's electricity bill is below the national average. Our goal is to keep bill increases at or below the rate of inflation – and this Resource Plan positions us well for success. In fact, our Preferred Plan achieves over 80 percent carbon reductions (from 2005 levels) for a nominal customer cost of just over one percent Compound Annual Growth Rate (CAGR) over the plan period. The opportunity to achieve such significant reductions in our carbon emissions for a nominal increase in cost is one of the principal benefits of our Preferred Plan. The following graph shows the relative cost growth of our Preferred Plan in comparison to the national average:

Figure 1-5: Preferred Plan Average Rate Impact for the NSP System



To be clear, the resources the Company needs to add over the next 15 years to continue providing safe and reliable service, to comply with state energy requirements, and to address plant retirements and PPA expirations come at some cost. But we believe that cost – which keeps rates at or below the level of inflation – is both modest and appropriate compared to the substantial benefits we have described here.

III. CONCLUSION

Our Preferred Plan – which accounts for more variables and changes than any other previous Xcel Energy resource plan – proposes to eliminate coal, add even more renewables, and continue our industry-leading EE and DR programs, all while preserving reliability and affordability for our customers. It also meets the varied interests of our five-state Upper Midwest region. And by planning ahead and charting an orderly, gradual transition of our generation fleet, we believe we can achieve all of these goals while managing the impacts to our host communities and employees, preserving the reliability and stability of our system, and maintaining affordability for our customers. For these reasons, and those discussed throughout this filing, we believe our Preferred Plan is in the public interest and merits Commission approval.

CHAPTER 2
PLANNING LANDSCAPE

I. INTRODUCTION

Northern States Power Company, doing business as Xcel Energy, submits to the Minnesota Public Utilities Commission this 2020–2034 Upper Midwest Integrated Resource Plan, which eliminates coal-based generation from our system by 2030, proposes to add thousands of megawatts of renewable resources – and charts the path toward achieving some of the most ambitious carbon reduction goals of any utility in the United States.

Northern States Power Company-Minnesota is a wholly-owned operating subsidiary of Xcel Energy, Inc. that owns and operates, in conjunction with its affiliate Northern States Power Company-Wisconsin, the integrated NSP System of generation and transmission assets that serves more than 1.8 million customers in Michigan, Minnesota, North Dakota, South Dakota, and Wisconsin. This Resource Plan builds on our strong foundation of cost-effective environmental performance and the generating fleet transition we began in our last Resource Plan.

Our plan is founded on unprecedented levels of stakeholder engagement and technical analyses that examined an orderly retirement of our baseload generating units. We analyzed numerous assumptions and sensitivities to identify the plan that best meets customer needs, achieves our obligations and goals, and ensures we maintain a resilient and reliable grid. The Preferred Plan we propose emerged as the best suite of resources that balances our planning objectives, as follows:

Figure 2-1: Xcel Energy Integrated Resource Plan Objectives

To understand our Preferred Plan, we first present a Reference Case. The Reference

Case is the baseline scenario identifying the resources necessary to continue meeting our customers' needs, comply with renewable energy requirements, achieve our 80 percent CO_2 reduction from 2005 levels objective, add 400 MW of incremental Demand Response (DR) consistent with the Commission's Order in our last plan, and achieve the significant EE targets identified in the *Minnesota Energy Efficiency Potential Study*.[1]

The Commission's Rules provide the factors to consider in issuing its findings of fact and conclusions.[2] In addition to considering the characteristics of the available resource options and of the Preferred Plan as a whole, resource options and plans must be evaluated on their ability to:

A. Maintain or improve the adequacy and reliability of utility service,
B. Keep the customers' bills and the utility's rates as low as practicable, given regulatory and other constraints,
C. Minimize adverse socioeconomic effects and adverse effects upon the environment,
D. Enhance the utility's ability to respond to changes in the financial, social, and technological factors affecting its operations, and
E. Limit the risk of adverse effects on the utility and its customers from financial, social, and technological factors that the utility cannot control.

Our Preferred Plan meets these criteria, and provides the flexibility to address the evolving planning landscape, including the changes we expect to the NSP System to achieve our ambitious vision of a 100 percent carbon-free energy mix by 2050. That said, we respectfully request the Commission to approve our Preferred Plan, as follows:

- ***Coal Resources.*** Retire our last two units early: King in 2028 and Sherco Unit 3 in 2030. Additionally, continue our plan to retire Sherco 1 and 2 in 2026 and 2023, respectively.
    - Our plan also commits to offer Sherco Unit 2 into MISO on a seasonal basis until its retirement, and working with our employees at, and the communities around, the Sherco and King plants to support them through the transition of our remaining coal fleet.
- ***Nuclear Resources.*** Operate our Monticello unit through 2040 (10 years longer than its current license) and operate both Prairie Island units through

[1] Available at: http://mn.gov/commerce-stat/pdfs/mn-energy-efficiency-potential-study.pdf
[2] Minn. R. 7843.0500, subp. 3

the end of their current licenses (PI Unit 1 to 2033 and PI Unit 2 to 2034).[3]

- We expect to initiate a Certificate of Need proceeding with the Commission within the next five years and begin working toward license extension with the Nuclear Regulatory Commission during this timeframe.

- ***Renewable Resources.*** While the exact wind and solar mix could vary based on a variety of reasons, at this time we propose to add 4,000 MW of cumulative utility scale resources by 2034 (the first being in 2025) and approximately 1,200 MW of cumulative wind by 2034 to replace wind that is set to retire from our system during that period. We specifically request flexibility in the timing and amounts of renewable additions to take advantage of market and other conditions that we believe will provide value to our customers.
  - ***Wind.*** We are committed to pursuing repowering and/or contract extension opportunities for this resource and we intend to pursue incremental wind resources as needed to meet customer needs in growing customer programs like Renewable*Connect.
  - ***Solar.*** Our Preferred Plan proposes an initial planned addition of 500 MW in 2025. Our plan includes forecasted growth of distributed solar. If actual distributed solar capacity exceeds our expectations, we anticipate this will displace a portion of our proposed grid-scale solar resources.

- ***Combined Cycle Resources.*** Acquire and operate the Mankato Energy Center and build, own and operate (Sherco CC) to satisfy significant capacity and operational need created by coal closures.[4]

- ***Firm Load Supporting Resources.*** Extend the life of Blue Lake Units 1-4 through 2020-2023.[5] Add approximately 1,700 MW of cumulative firm dispatchable, load-supporting resources between 2031-2034. Because these units are not needed until the out-years of our current plan, we have not identified a specific resource type to meet this need. With the expected price declines and technology development between now and the 2030s, we believe utility-scale storage will be an integral resource used to meet this need.

- ***Demand Side Management.*** EE programs representing 2-2.5 percent of savings annually (over 780 GWh for each of 2020-2034), compared to average

[3] Given that our operating licenses for Prairie Island run until 2033 and 2034, we believe there is sufficient time to address the future of that plant in upcoming resource plans.
[4] MEC is currently pending Commission consideration in Docket No. IP6949, E002/PA-18-702. For the Sherco CC, we expect to submit our plans in a separate proceeding.
[5] Pending decision in Docket E,G002/D-19-161.

annual energy savings of 444 GWh in our last Resource Plan, and the addition of 400 MW of DR by 2023. We are requesting the flexibility to evaluate and pursue the required incremental DR through a variety of means and technologies over the coming years.

- ***Storage and Other Emerging Technologies.*** Pursue storage and other emerging technologies, on both a large and small scale.

Finally, as we have previously discussed, system retirements will impact our current blackstart plans, or our ability to restart the system in the event of a catastrophic failure. While we do not propose any action related to the system blackstart at this time, we anticipate addressing this in our next Resource Plan or earlier, if system needs dictate the need to do so.

The balance of our Resource Plan discusses the evolving planning landscape, presents our Preferred Plan and the economic modeling framework from which it emerged, and estimated customer cost and rate impacts. We additionally provide Appendices that include the results of our Baseload Study, Load and Distributed Energy Resource (DER) forecasts, and discussion about our Supporting Transmission and Distribution Infrastructure, Environmental Regulations and Compliance, and numerous others.

II. PLANNING LANDSCAPE

Every business that conducts long term planning needs to account for both its internal goals and the external environment within which it operates. In this Chapter, we discuss some of the key internal and external market contexts that affect how we have developed, and plan to execute on, our Preferred Plan – which supports our ambitious carbon reduction vision, to reduce our carbon emissions to 80 percent below 2005 levels by 2030.

Specifically in this section we examine:

- Xcel Energy's Carbon Reduction Goals
- Regional Reliability and Market Constructs
- Distributed Energy Resources (DER)
- Community and Employee Considerations
- Customer Preferences
- Supply and Technology Trends
- Jurisdictional Updates

While all of these factors affect how we develop our plan, a few stand out above others as being particularly influential in this Integrated Resource Plan cycle – chief among them, regional market constructs and renewable integration. While the regional system operator that designs many of our market and planning requirements continues to examine the effects of high renewable adoption on the grid, it has not yet developed robust and forward-looking capacity accreditation constructs to account for how renewables' contributions to peak demand will change over time. This introduces complexity to designing a plan far into the future, and how we carry out those plans.

Likewise, while we are committed to substantially increasing renewables on our system to achieve our carbon reduction goals, we also anticipate facing challenges to integrating this new clean generation, given the delayed interconnection studies and current limited state of open transmission availability. Our ability to connect these new renewables in a cost-effective manner depends materially on constructs that enable careful management of our interconnection rights in the near-to-medium term as well as new transmission in the long term.

These and other factors, such as DER adoption rates, community and employee impacts, and satisfying the needs of five different states, all affect how we developed the Preferred Plan presented in this filing – and the issues we anticipate encountering as we pursue our goals to lead the energy transition while keeping our grid services

reliable and affordable.

A. Carbon Reduction Goals

In December 2018, the Company announced its goals to reduce carbon dioxide (CO_2) emissions 80 percent by 2030 below 2005 levels companywide, and to serve customers with 100 percent carbon-free electricity by 2050. We believe our 2030 goal is achievable with the clean generation and energy storage technologies available today. We believe our 2050 vision, however, will be achievable only with advancements in new technologies such as: carbon-free dispatchable generation technologies and longer-duration storage that are not currently available at the necessary scale and cost, or carbon capture and sequestration. Until these or other technologies are further developed and commercialized, we will require a certain amount of conventional flexible and dispatchable generation to integrate increasing levels of renewables on the grid.

To achieve our 80 percent reduction by 2030 goal, we anticipate the following elements will be essential parts of future plans, across one or more of our service areas:

- Adding thousands of megawatts of additional renewable resources to our system and incrementally retiring emitting baseload generation, while also incorporating flexible, dispatchable generation to enable grid reliability throughout this transition;
- Operating our carbon-free nuclear units at least through the remainder of their licenses, with the potential for license extensions;
- Supporting the strategic electrification of certain end uses and enabling flexible demand, which will help to reduce carbon emissions in other sectors while also providing flexible loads to help integrate more renewables;
- Investing in critical infrastructure, such as transmission and advanced grid technology on our distribution system, to integrate the DER our customers choose, as well as improve reliability and the customer experience.

These goals, the science behind them, and the path we will take to achieving them, are all detailed further in Appendix E: Xcel Energy Carbon Report:Building a Carbon-Free Future.

With these aggressive carbon goals in mind as one of the main tenets of our Preferred Plan, below we discuss the key forces that affect how we have developed, and plan to execute on, our Preferred Plan.

B. Regional Reliability and Market Constructs

The Company's Upper Midwest system is part of the Midcontinent Independent System Operator (MISO) market. MISO is charged with several responsibilities, chief of which are overseeing wholesale energy markets in the member region and planning for bulk system reliability (i.e. transmission planning, generator interconnection, and ensuring sufficient reserve margins). Many aspects of MISO's operations affect how we conduct resource planning, but here we focus primarily on system reliability constructs that will be increasingly tested as we and others transition to a fuel mix relying on more variable renewable resources.

1. Reserve Margin

One of MISO's core responsibilities includes administering resource adequacy requirements to enable utilities like us, and other Load Serving Entities (LSEs), across the region to fulfill their obligation to serve customers reliably. Trends are emerging, however, that raise questions regarding how planning constructs will adapt to ensure the system remains reliable as emitting, but stable, baseload generation continues to retire and be replaced by clean, but variable, renewable energy.

MISO and its system reliability oversight organization, the North American Electric Reliability Corporation (NERC) undertake studies to determine the appropriate level of reserve capacity that should be maintained, what affect a resource retirement has on the broader system, and how increasing renewable adoption will change how they analyze and ensure grid reliability. All of these studies point toward an increasingly complex grid that will have to be carefully managed through the transition to a lower-carbon future.

MISO's Planning Reserve Margin (PRM) analysis is one important piece of the current reliability planning paradigm. The PRM is an estimation of how much generating capacity, over and above expected customer load, needs to be present on the system to ensure reliability in all but the most extreme circumstances (called a 1-in-10 year Loss of Load Expectation or LOLE). In the 2018 report, MISO established a reference planning reserve margin of 17.1 percent for the 2018-2019 planning year; in other words, they determined that the total installed capacity available on the system should be 17.1 percent higher than the system's peak load.[6] This reference threshold is provided to the NERC, which sets standards and studies

[6] MISO's PRM for the 2018-2019 Planning Year indicates a PRM for both installed capacity (ICAP) and a rating that derates capacity to account for potential outages (called UCAP). The UCAP PRM for the 2018 planning year is 8.4 percent These two measures of PRM are discussed further in the next section on Minimum System Needs.

reliability across the continent, and of which regional system and transmission operators like MISO are a part.

As part of its oversight and governance activities, NERC conducts a reserve margin analysis across all system operators in North America, in a report called the Long Term Reliability Assessment (LTRA). The 2018 LTRA indicated that MISO is one of three regions that are projected to drop below their reference reserve margin levels by the year 2023, unless certain measures are taken.[7] This report indicates that inclusion of Tier 2 resources (those that are in more advanced stages of planning but not yet under construction) would likely allow for the MISO footprint to preserve system reliability. However, the unprecedented rate of announced, but not yet evaluated, baseload generation retirements and uncertainty in future firm capacity additions creates a tension between maintaining reliability and transitioning away from baseload generation.

It is important to note that retiring some baseload generation and transitioning to a cleaner grid with more wind and solar does not present an insurmountable challenge; indeed we are proposing to retire all of our coal by 2030. Rather, the transition will need to be actively and carefully managed, likely with incremental retirements and supporting transmission upgrades that are carefully studied.

2. Renewable Integration Challenges

In addition to challenges around baseload retirement issues, we also see planning issues developing around how renewable additions are evaluated for their reliability impacts. In the aggregate, when MISO has studied high levels of renewable penetration on the grid, grid instability increases and capacity values of variable resources decline, sometimes significantly. Retaining firm dispatchable generating units helps ensure the system will continue to operate reliably.

MISO has also recognized that its capacity accreditation framework – the manner by which it assesses variable renewables' ability to contribute to peak demand needs – will likely change as these resources become more prevalent on the grid. However, MISO has not yet developed sufficiently robust forward guidance for resource planning processes to account for how those values might change in the future, which creates uncertainty in the resource planning process. We discuss these renewable integration studies and specific capacity accreditation issues in more detail below.

[7] *See* "NERC Long Term Reliability Assessment 2018" at 14. Available at: https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2018_12202018.pdf

a. Renewable Integration Impact Assessment

In preparation for an expected future grid with high levels of non-dispatchable renewable penetration and declining baseload generation, MISO is undertaking additional studies with respect to its system's reliability and resource adequacy of its system. The *Renewable Integration Impact Assessment* (RIIA) seeks to inform future long-term planning by understanding what the power system will need to operate reliably with these high levels of variable resources, specifically by examining operational adequacy, transmission adequacy, system stability and resource adequacy limitations.

In Phase I, the study examined a scenario in which variable generation achieves a 40 percent share of the total capacity on the MISO system. It found that the complexity of operating such a system reliably is significantly higher than that of even a system with 30 percent variable resources. Under the circumstances studied, the system experienced more dynamic stability issues and other operational stressors, and resource adequacy requirements increased. For example, the modeled system exhibited high levels of energy curtailment and very high ramping rates in the hours when variable resources were not always available to meet demand. In this scenario, loss of load projections were narrowed to fewer likely hours during the year, but the probability of occurrence increased significantly over the current state. This points to the value that flexible, dispatchable resources supporting grid stability continue to provide in these scenarios; while they run for fewer hours than the current market constructs would warrant, they need to be able to respond quickly, moving from minimum generation levels to higher levels of output to meet these fluctuations in net load quickly.

Further, at high levels of wind and/or solar adoption, the RIIA study found that appropriate resource adequacy values to assign these resources degraded, sometimes significantly from current levels. As a key piece of planning our future system, these resource adequacy capacity accreditation values are discussed in more depth below.

b. Capacity Accreditation Values

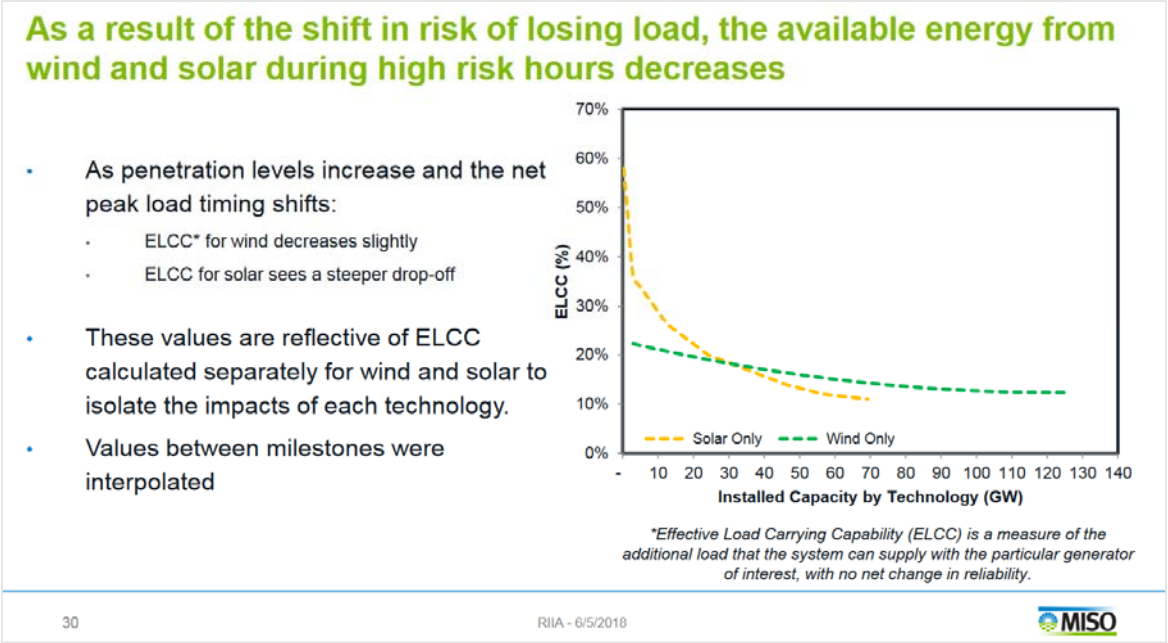
Variable renewable resources such as wind and solar are becoming more cost competitive and utilities across the region, including the Company, are increasingly adopting these technologies as important components of their resource mixes. This generation is largely displacing more traditional, thermal dispatchable units. As variable resources are dependent on natural resource availability in a given moment (i.e. wind blowing or sun shining), their capacity does not replace retiring dispatchable units one-for-one in terms of the amount of energy it produces, or assurance that this capacity will produce energy when needed. To account for this, MISO applies a

certain accreditation discount to these resources to get a more appropriate probabilistic view of how much capacity can be counted on to contribute to peak demand across the year. This is captured in a measure called the Effective Load Carrying Capability (ELCC).

These administratively set values have a significant impact on how we achieve our carbon reduction goals while maintaining affordable and reliable service. Currently, MISO assigns wind generation an average ELCC value of 15.7 percent; meaning that for every 100 MW of wind installed, only 15.7 MW can be counted as capacity toward the planning reserve margin. For new solar resources, in the absence of an observed historical value, MISO assigns the current initial year default ELCC of 50 percent. The appropriateness of these values in reflecting actual grid conditions is dependent on the pace at which wind and solar penetration increases on the grid, and subsequently how MISO conducts review and adjusts the values. The ELCC is currently evaluated as an annual average, and forward values are not projected.

In reality, however, the capacity value these intermittent resources can provide are subject to diminishing marginal returns. When a single variable resource type increases its penetration level on the grid, each incremental unit of capacity inherently provides a little less capacity benefit to the system than the last unit. For example, MISO's RIIA study estimates that solar in particular would experience steep ELCC reductions within the first 10 gigawatts installed, and this value continues to drop off at higher levels of adoption. Further, in particular for these variable assets, the realized capacity value may change throughout the year, as the capacity value a wind or solar plant can provide reasonably changes in accordance with seasonally variable environmental conditions.

Figure 2-2: Modeled Wind and Solar ELCC as Penetration Increases[8]



The operational realities surrounding future variable resource additions and their seasonal aspects aside, we continue to use the administratively-set annual average ELCC levels in our planning that MISO has established for today's market.

While we recognize that it is difficult for MISO to accurately project future wind and solar penetration levels and load shapes (two key variables in determining future ELCC values), this presents a key challenge as we plan our future system. As the ELCC construct does not currently provide forward-looking values, we have to apply current values to our resource modeling process, even though we are modeling 15 years into the future. However, we know in reality that these values will degrade as we and others add variable renewables to the MISO system, and so what appears to be a net capacity surplus today may look rather different in future assessments.

It is worth noting here that we may encounter changing assumed resource adequacy contributions for use-limited resources in the future as well. In general, resources such as DR and energy storage would be subject to declining ELCC values as they become more prevalent on the system, in the same way wind or solar ELCCs realistically decline.[9] Notably, MISO is also considering changes to how it accounts

[8] MISO. *"Renewable Integration Impact Assessment"* Workshop presentation June 5, 2018. Available at: https://cdn.misoenergy.org/20180605%20RIIA%20Workshop%20Presentation213125.pdf

[9] *See* the E3 Study in Appendix P2 for further discussion on how marginal ELCC for DR and energy storage resources may decline as adoption increases.

for DR's capacity accreditation overall, such as enforcing more stringent testing requirements. MISO is also following up on actual performance during DR events, which may result in accredited value reductions going forward. Both these factors mean that the DR we currently depend on as a baseline resource in our portfolio, in addition to that which we may select in this or future resource plans, may not yield the same benefits in future years as we have historically expected.

c. Interconnection Queue

The current state of grid interconnection processes and transmission capabilities in MISO introduce complexity not only to our planning processes, but also how we execute on the plan.

The MISO generator interconnection process is designed to allow generators reliable, non-discriminatory access to the electric transmission system, in a timely manner, while maintaining transmission system reliability. Recently, as the number of proposed projects in MISO has expanded significantly, this process has been mired in delays. Delay impacts are particularly evident in the Definitive Planning Process (DPP) phases, where MISO undertakes generation interconnection studies. Current studies are a number of months behind, due to the large volume (including speculative requests) and a generator interconnection process that allows late withdrawals from the queue with limited consequences. Despite some recent process reforms, MISO has not been able to keep pace with the expanding queue. And where projects do make it through the DPP, they are sometimes assigned high transmission system upgrade costs that challenge the project's economic viability. MISO's interconnection challenge is multi-faceted.

First, there is a substantial volume of capacity currently in the queue requesting study and interconnection approval. As of early June 2019 there were over 100 GW of new capacity in the active MISO queue (although this number has fluctuated substantially), the vast majority of which is comprised of wind and solar projects.[10] Each cycle of the DPP is handling expanding levels of requested capacity; for example, the recently completed cycle for the MISO West region (started in August 2016) started out with 31 projects totaling just over 5,600 MW.[11] The April 2019 DPP study cycle,

[10] MISO "Generator Interconnection: Overview." Updated as of June 1, 2019, at: https://cdn.misoenergy.org/GIQ%20Web%20Overview272899.pdf
[11] *See* "MISO DPP 2016 August West Area Phase 1 Study." Siemens (August 20, 2018). Available at: https://cdn.misoenergy.org/GI_DPP_2016_Aug_West_Phase1_SIS_Report277263.pdf

scheduled to begin in March 2020, includes 58 projects totaling 8,800 GW in the same area.[12] While the level of proposed new renewable project is a positive indication of aspirational renewable development in the region, MISO has also indicated that a substantial amount of this capacity is speculative, in early stages of project development or representing duplicative requests.

Further, the existing transmission system's capability to interconnect new projects without substantial infrastructure upgrades is limited, and thus, the generation interconnection planning studies indicate there will likely be costly upgrades assigned to the prospective generators. In the past, initiatives such as CapX2020 and Multi-Value Projects (MVPs) were able to integrate large quantities of new renewable power and socialize transmission infrastructure costs across a larger swath of benefitting MISO customers. However, wind power in particular expanded on the MISO grid faster than expected, and the interconnection capacity afforded by these projects has been largely used. Since then, few new transmission lines have been proposed or approved for the purposes of renewable integration.

Generally speaking, this means that, if new generation projects in the queue want to interconnect, the generation interconnection study process identifies substantial additional transmission system upgrade costs and assigns them to the generation owner(s). In the aforementioned MISO West DPP cycle that recently completed, for example, the approximately 5,600 MW of proposed projects were expected to incur approximately $3.2 billion in transmission upgrades, if all were to interconnect to the system.[13] These assigned high-cost transmission system upgrade requirements can sometimes render projects uneconomic, forcing a queue withdrawal and additional MISO study on the remaining projects.

d. Regional Seam Issues

Limitations on transmission infrastructure and coordination, both within MISO and between MISO and the Southwest Power Pool (SPP), illustrate further challenges.

Within MISO, the transmission system is showing constraints and the resulting curtailment slows our progress toward a cleaner energy future across the Upper Midwest system. Currently, wind generation from the western part of MISO flows toward the load centers in the east such as the Minneapolis–St. Paul area and load centers across the transmission interconnection between Minnesota and Wisconsin. However, existing west-to-east transmission capacity is, at times, operating at its limit.

[12] *See* MISO "Definitive Planning Phase Estimated Schedule." Updated as of June 1 2019. Available at: https://cdn.misoenergy.org/Definitive%20Planning%20Phase%20Estimated%20Schedule106547.pdf
[13] "MISO DPP 2016 August West Area Phase 1 Study." Siemens, September 2018, at xvii.

The transmission interface across the Minnesota-Wisconsin border in particular is currently stability-limited, and trying to force additional renewable energy through these lines could result in voltage collapses in Northern Wisconsin that would destabilize the grid. Curtailing this energy at its source in the west is operationally and economically inefficient, keeping us from fully utilizing the inexpensive and clean energy to which we have access; but, without additional transmission capacity, we will more frequently encounter this problem as we add more renewable generation to our system.

Further, coordination (or historical lack thereof) between MISO and SPP introduces challenges to bringing onto the system, and utilizing, more clean energy. First, for projects that can be considered interregional in nature, a project must currently meet economic benefit hurdles in a joint review, as well as separate MISO and SPP regional evaluations. This slows the process significantly, and may overestimate the amount of interconnection upgrades required, adding to project uncertainty and cost.

Second, although our load and generation sit within MISO, the nature of power flows inevitably results in some of our energy entering the SPP system. In turn, both MISO and SPP may charge to transmit that energy from the point of generation to the load, challenging a project's economic viability or raising customer costs for projects already online.

Finally, MISO and SPP disagree on what should happen when one region or the other has to "lean" more on the system than its contracted delivery amounts for a certain time. Where SPP would levy penalties in this scenario, MISO views this situation as a normal and acceptable result of an integrated grid. All of these issues increase transaction costs and uncertainty for a given generation project coming online, and represents a potential barrier to efficiently bringing additional renewable generation to the grid.

3. Mitigation Efforts

In response to direction from FERC and in recognition of the challenges described above, MISO is undertaking several actions that could serve to mitigate challenges to bringing new, clean resources online. In essence, they allow generation owners to leverage existing interconnection agreements to maximize utilization and fit renewable additions into the relatively few remaining open spaces on the grid. While we expect these processes to mitigate some of the near term challenges to additional renewable capacity, they do not address all challenges (in particular our ability to depend on neighboring regions for renewables and maintaining reliability) and we expect that longer term solutions will eventually need to be developed.

a. Generator Replacement Process

Interconnection study delays and speculative queueing are challenges not only to projects that are actually commercially viable, but also to generation owners that are looking to retire aging assets. Companies that are required to meet a certain level of reserve capacity, like Xcel Energy, face potential compliance and commercial risk if we retire existing assets without the ability to re-utilize that interconnection capacity. Recognizing these issues, MISO filed and received approval for a proposed Replacement Generator Process that would allow current generation owners to retain and re-utilize these interconnection rights where a resource plans to retire, within certain technical limitations on the new generator's attributes. The new generating units could be developed on the same site, or on a site in close proximity that uses the same grid interconnection point. Per the new MISO tariff provisions, the new generation resource would need to have an in-service date not later than three years after the existing generator ceased operation. Importantly, these projects would be studied outside the traditional DPP timeline, with the intention of avoiding the significant delays associated with that process, as described above.

b. FERC 845

In 2018, FERC issued Order 845, *Reform of Generator Interconnection Procedures and Agreements*[14] that also opens additional opportunities for generation owners to add resources to the system outside the normal interconnection queue process. The Order directs all transmission providers to develop a procedure to allow interconnection customers to use surplus availability at an existing point of interconnection without that new project entering the full MISO queue and planning process, within certain technical limitations. MISO has referred to surplus interconnection availability as "Net Zero" interconnection, as the addition of this new project would not result in an overall increase to the interconnection capacity requirements of the site; rather, it would be expected to increase the overall *utilization* of the interconnection site.

While MISO allowed Net Zero resources prior to FERC 845, the new Order also allows existing interconnection rights owners the first right to utilize the surplus availability on that interconnection. It also revises the definition of a generating facility to explicitly include energy storage resources. These actions work to support generation owners increasing renewable utilization on existing interconnections, and could support future project hybridization (e.g. solar and storage or wind and storage). We expect that generator replacement, Net Zero, and other FERC Order

[14] See Reform of Generator Interconnection Procedures and Agreements, 163 FERC ¶ 61,043 (2018) (Order No. 845).

implementation efforts will alleviate some of the barriers to planning and executing on a future with substantial renewable additions. However, these do not address the underlying challenges around queue length and timeline, intra-MISO and interregional seams congestion challenges, and integrating high levels of renewables reliably and affordably. MISO has recently attempted to mitigate the queue volume challenge by proposing process reforms that increase the stringency of entering this phase of interconnection process; however, while recognizing the challenges MISO faces, FERC recently rejected the proposal.[15] While the Company and others have begun contemplating new MVP-like projects, the lack of alignment across MISO and long lead-times required for such projects mean that these challenges are unlikely to be resolved in the near term.

C. Distributed Energy Resources

At the same time as we work to clean our power supply, we also recognize that customers are now exercising more choice around how and from where they consume energy. This is a key consideration as we plan our resource mix for the next 15 years.

Some customers are choosing DER that can reduce customer consumption and even provide energy back to our system from decentralized locations on the grid. Examples of DER include, but are not limited to: rooftop solar panels, energy storage, community solar gardens, or the EE enabled by a smart thermostat or time of use electric rate. To-date, community solar gardens makes up the clear majority of the DER on our system in the Upper Midwest.

Our customers' adoption of DER and new types of load mean that consumption patterns from our centralized power system are changing. This can represent an opportunity: if we can harness the benefits of these resources to make demand more flexible, we can use this to better match demand to energy production from our large, variable renewable resources. For example, we could utilize managed or "smart" charging of electric vehicles (EVs), to delay charging to off-peak hours or to times when renewable output is the highest. We could also use advanced metering technology alongside customer programs and tariffs to enable load shifting away from peak hours.

There are also DER coming onto our grid, in the form of electric transportation options – enabling not only flexible load opportunities but also broader economy-wide emissions reduction – and we have developed several programs and rate options

[15] *See* FERC "Order Rejecting Tariff Revisions re: Midcontinent Independent System Operator, Inc. under ER19-637." Available at: https://elibrary.ferc.gov/idmws/file_list.asp?accession_num=20190319-3076

to encourage that adoption.

The transportation electrification initiatives we have implemented and continue to develop are not only enabling customer choice, but also to the broader economy in helping to meet greenhouse gas (GHG) emissions reductions goals. The transportation sector is now the leading contributor to Minnesota's overall emissions,[16] and as our system (and the state's electric sector more broadly) continues to transition to a cleaner energy mix, transportation's share of GHG emissions will continue to expand. This shift highlights an opportunity for the electric sector to facilitate GHG reductions in the transportation sector, as electricity is increasingly used for transportation fuel.

While the opportunities are exciting, it is also important to recognize that customer adoption of DER and new types of load behind the meter introduce uncertainties in our planning processes, particularly if we do not have adequate visibility into how and when that new DER or demand is coming onto our system.

One tool we have to mitigate this DER and electrification uncertainty is our Integrated Distribution Plan (IDP) and grid modernization efforts. Our IDP process and proposed investments will help us leverage DER and new load to enable more flexible demand management, improve reliability and, we anticipate, enable better decision-making about large-scale investments as well. In our last IDP we discussed these enabling technologies, which include: Advanced Distribution Management Systems (ADMS), which will allow us to better integrate DER onto our grid and maintain reliability; the Field Area Network (FAN), which enables two-way communication from field devices and Company back office operations; Advanced Metering Infrastructure (AMI), which enables time of use rates by metering consumption at smaller time intervals; and automated, remote reliability-sensing and enhancing technologies such as and Fault Location, Isolation, and Service Restoration (FLISR). Many of these investments will help us develop capabilities to use load more flexibly. We also hope to enhance the customer experience by creating new programs and offerings that fit their needs and preferences based on the capabilities these investments provide.

Our Preferred Plan is substantially dependent on anticipated customer load, which incorporates the best estimates we have about customer adoption of DER, as well as robust statistical forecasting methods. We have also modeled sensitivities to address some of this uncertainty. But we still often do not have visibility into which

[16] See the Minnesota Pollution Control Agency's statewide GHG inventory data, available at https://www.pca.state.mn.us/air/greenhouse-gas-emissions-data.

technologies, and at what pace, customers will adopt and thus, how that changing load will affect our grid needs in the future.

D. Community and Employee Considerations

As we move forward with our carbon reduction goals, we are cognizant that phasing out some of our legacy generation assets has a significant impact not only on our energy mix, but on the economies of communities where those plants are located and the employees who work in those plants. This is particularly true of our coal facilities, where the plants are prominent places of employment and contributors to the property tax base in the community. This is why we make efforts to spur economic development in locations where our current units will eventually be phased out.

For example, since our most recent Resource Plan, where we proposed to retire the Sherco 1 and 2 coal units in Becker, we have worked extensively with local units of government, community stakeholders, and the State to draw new development to support the local economy. This includes a planned CC generating unit at the Sherco site, the relocated Northern Metal Recycling facility, and, prospectively a new Google data center with energy matched by a wind facility. Some of that activity (e.g. the Google data center) is also anticipated to spur new renewable energy development on our system.

Related, we are participating in a study overseen by Center for Energy and Environment (CEE) that will examine the impacts of the large baseload generation plants in Minnesota on the host communities. The other participants in the study include the Coalition of Utility Cities, Minnesota Power, and the Prairie Island Indian Community. The study will consist of a quantitative and qualitative component. The quantitative component of the study is similar to the study we conducted for Sherco 1 and 2 in our last Resource Plan. For the qualitative component, CEE will engage with host community residents and business to gauge awareness, opinions and concerns around potential power plant closures. Efforts on both components are underway and we will supplement this Resource Plan filing when each component is completed. As this docket progresses, we expect to be able to incorporate further findings and hold additional discussions incorporating the finalized report outcomes. Further discussion of the scope and status of this study is included as Appendix O2.

In addition to community impacts, we are also aware that these plant closures impact our employees and their families. With this in mind, and consistent with our past practices, we will work with these impacted employees to transition them to other Xcel Energy plants or areas of the company. In the past, when plants have been closed or converted (and impacted headcount) we have provided résumé writing

services, support for interview practice, job training, and job shadowing opportunities. Through natural attrition and job relocations, we have been able to successfully "re-home" nearly all impacted employees from plant closures and conversions to-date.

Moving forward we will work with local unions and set a course to negotiate multiskilling for our impacted sites. This skill set will position our employees for other job opportunities within Xcel Energy. As we get closer to closure dates, temporary workforce will be utilized to back fill benefit employees who have relocated to other positions within the company. This strategy lessens the burden and stress for benefit employees to find positions, as plants near closure dates. In addition, plant management, Work Force Relations and Human Resources will work together with other business organizations within the company to help coordinate interviews for affected employees.

And, as we continue toward achievement of our aggressive carbon goals, we will continue to make significant investments in clean energy in the states we serve. As we do so, we will look for opportunities to create fair access to clean energy programs, jobs and economic development opportunities. Going forward, we continue to be dedicated to working with employees, communities, and stakeholders to manage community impacts throughout our clean energy transition.

E. Customer Preferences

Our Upper Midwest system continues to serve a diverse mix of customers with varied interests and preferences. While most customers continue to prioritize affordability, we have seen increasing interest in sustainability, carbon reduction, and clean energy objectives. Again, these are important considerations to keep in mind while planning our resource mix for the future.

1. Municipal

Cities and municipalities are increasingly setting and developing strategies around sustainability and climate goals. In fact, there are 11 cities in our Upper Midwest jurisdiction that have set carbon reduction or renewable energy goals. Minneapolis is the most prominent example, as evidenced by the Clean Energy Partnership that had just started when we filed our last Resource Plan. Since then, the partnership has flourished and advanced, helping to achieve progress toward the city's sustainability goals. Other municipalities and communities are also developing goals and action plans around renewable energy and climate goals. We work with many of these communities through our Partners in Energy program to support achievement of these goals.

2. Commercial and Industrial Customers

Our commercial and industrial customers place a high priority on keeping costs low to remain competitive in their own markets. This is particularly true of large industrial customers, where energy costs can make up a substantial portion of their operating expenses. However, corporate efforts to achieve sustainability goals are also increasing, both in the US broadly and within our system. And as the cost of renewable energy declines, affordability and sustainability goals increasingly go hand in hand. Within our system, several of our corporate customers are co-members of the Minnesota Sustainable Growth Coalition, which is a business-led public-private partnership working to advance clean energy and other sustainability and circular economy objectives. We hear from these and other corporate customers across our Upper Midwest system that sustainability and clean energy are important to them, and they want us to offer products that meet these needs, and Renewable*Connect is one such product.

In 2015 we worked with customers to develop Renewable*Connect. The program achieved full subscription in its first year, and in January 2019 we filed for an expansion of this program, and included an option for high load factor customers (i.e. those that operate continuously during the day) to be served primarily with competitively priced wind and a smaller portion of solar. Significantly, this program advances the sustainability goals of the participating companies without creating additional costs that must be carried by other, non-participating customers. In 2019, we also developed a new program called Certified Renewable Percentage (CRP). The CRP is a new Renewable Energy Certificate (REC)-based accounting methodology that clarifies the percentage of our system energy delivered to customers that is renewable. The CRP is not a subscription service or program customers need to enroll in. Instead, the Company will retire sufficient RECs on behalf of all our retail customers such that the total RECs retired annually reflects the portion of delivered energy that is renewable. This will allow all retail customers to claim the percentage of renewable energy on the system as the starting point towards their sustainability goals.

Our willingness to work with customers to balance clean energy objectives and affordability needs, while facilitating economic development opportunities, has also attracted new customers to the service area. The new Google Data Center slated for development in Becker is a clear example. Google has an objective to match 100 percent of its energy consumption needs with renewable energy purchased from incremental projects, and has future plans to go even further by sourcing carbon-free energy for its operations on a 24/7 basis. We were able to work together with Google to develop a proposal to help it achieve its renewable energy goals.

3. Residential Customers

Residential customers likewise tell us that they value choices and clean, affordable, reliable energy. In response, we have developed programs that offer more convenient payment options, rebates for EE upgrades, and the chance to reduce the environmental impact of their consumption by choosing renewable energy. Customers are taking advantage of these programs in large numbers – and they have expressed strong satisfaction with their ability to select programs that best meet their individual energy needs.

F. Supply and Technology Trends

Trends around the supply of generation and energy storage equipment we need to fulfill our resource plan have a significant impact on the mix and timing of our resource proposals.

In the years since our last Resource Plan, wind and solar technology costs have continued to improve overall; solar in particular has experienced significant cost declines, with installed costs falling over 35 percent on average since 2015.[17] Consistent with past years, we generally expect wind and solar capital costs will continue to decline, although at perhaps a slower pace as these technologies advance on their respective maturity curves. We also expect technology advancements improve capacity factors. These two factors continue to improve the cost competitiveness of wind and solar resources in real terms, changes to incentive policies notwithstanding, relative to the other resource options we may consider. For example, the National Renewable Energy Laboratory projects that large-scale solar prices could decline 17 percent in real terms over the next 10 years.[18] For modeling purposes, however, our generic representations of these resources are static in terms of capacity factor and accredited capacity, and we have represented the combined future cost and performance trends through the levelized energy cost forecast for these technologies.

We also continue to examine the role energy storage can play in meeting our system needs. The Company has been developing our experience around the type of services energy storage can provide to our system, through the operation of an existing

[17] Bolinger, Mark and Seel, Joachim. *Utility Scale Solar 2018 Edition*. Lawrence Berkeley National Laboratory September 2018. Available at: https://emp.lbl.gov/utility-scale-solar

[18] This projection reflects data provided by the NREL's *Annual Technology Baseline* report, which we use in our modeling. This trend reflects changes in projected solar levelized costs in real terms (2016$) and are not adjusted for the potential impact of tax credits.

pumped hydro facility in Colorado and several pilot battery energy storage installations across Xcel Energy's service areas. Technologically, we expect grid-scale energy storage will support our clean energy goals in the future, by helping us maintain grid stability and supporting peak management while integrating the higher quantities of intermittent renewable generation we envision on our system. We are committed to pursuing this technology although challenges remain, in particular for battery energy storage, to managing seasonal renewable energy variability and longer duration demand-shifting needs.

From a cost perspective, battery energy storage has experienced significant improvements over the last few years and we would expect battery energy storage costs to further decline going forward. There are also other battery chemistries and different types of storage that may emerge as technology research and development continues. While we are confident utility-scale battery storage will be a part of our long-term resource mix, we are also evaluating the potential for near-term battery storage around our service territories to fulfill distribution system or other needs.

Finally, as we have noted, achieving our 100 percent carbon-free electricity by 2050 goal will require further development of technologies that have not yet been identified and commercialized. While not included in our resource planning optimization, we continue to monitor industry activity around other emerging technologies that may contribute to achievement of our goals. In addition to potential new battery chemistries mentioned above, potential emerging clean energy technologies include advanced nuclear reactors, carbon capture and storage applications, hybridized gas-hydrogen generators, other types of energy storage technologies beyond batteries, and others. As new technologies achieve commercialization, we will remain technology agnostic as we consider including them in our future resource planning analyses.

G. Jurisdictional Updates

Our integrated Upper Midwest system provides service on a multi-jurisdictional basis to 1.8 million customers across five states. Through this integration, we have historically leveraged economies of scale to support needed investments. Each resource on the Upper Midwest system – whether generation or transmission – was developed in consideration of the whole system, to take advantage of the economies of scale available through integrated system planning. Below we provide a brief overview of key prevailing and emerging energy policy in Minnesota, North Dakota, South Dakota, Wisconsin, and Michigan, where these objectives may affect our future planning for the Upper Midwest system as a whole.

1. *Minnesota*

In 2007, Minnesota passed the Next Generation Energy Act, which set successive, economy-wide greenhouse gas reduction goals relative to 2005 levels; 15 percent below reduction by 2015, 30 percent below by 2025, and 80 percent below by 2050. Since that time, the electric sector has outpaced emissions reductions in all other sectors, achieving a 29 percent reduction below 2005 levels by 2016 (the most recent year reported). However, the state has missed its economy-wide goal, achieving approximately 12 percent reduction over the same time period.[19] This data drives our view that the electric sector can, and likely must, facilitate reductions in other sectors, such as transportation and building energy use, if Minnesota is to meet its economy-wide carbon reduction goals.

Specific to the electric sector, the Minnesota Renewable Portfolio Standard, passed in 2007, remains our prevailing clean energy requirement. The 2019 session included passage, however, of energy storage provisions that (1) enable utility-owned energy storage pilot projects, and clarifying cost recovery for such pilots, (2) requiring resource plans to include an Energy Storage Systems Assessment, including how storage may contribute to generation and capacity needs and ancillary services, and (3) requiring a cost-benefit study of energy storage systems by the Department of Commerce.[20] We provide our Energy Storage Systems Assessment in Appendix F7.

2. *North Dakota*

Since our last Resource Plan, we submitted a Resource Treatment Framework (RTF) simultaneously to the Minnesota Public Utilities Commission (MPUC) and the North Dakota Public Service Commission (NDPSC). The RTF filing was submitted to the NDPSC in compliance with a Commission Order adopting the Negotiated Agreement in the Company's last rate case,[21] with the purpose of establishing a framework to address the costs and benefits of the Company's Upper Midwest system resources in a way that was both fair to all customers and aligned with North Dakota's policy objectives.

In the RTF, we developed a proposal that evaluated four potential implementation structures: (1) legal separation of the North Dakota portion of the system; (2) pseudo

[19] *See* Minnesota Pollution Control Agency "Greenhouse Gas Emissions Data." Available at: https://www.pca.state.mn.us/air/greenhouse-gas-emissions-data
[20] "19-5227 – Omnibus Jobs, Economic Development, Comerce and Energy." Available at: https://www.senate.mn/committees/2019-2020/3098_Committee_on_Jobs_and_Economic_Growth_Finance_and_Policy/19-5227.pdf
[21] See North Dakota Case No. PU-12-813. In Minnesota, the Company submitted the RTF consistent with our commitments made in MPUC Docket No. E002/M-16-223

separation, applying generator-specific cost/benefit allocations; (3) proxy-pricing, which would replace the cost of a disputed generation resource with a proxy price deemed acceptable; or (4) gaining regulatory alignment in the selection of resources, so that all states could fully participate in the integrated NSP system. Our intent was to seek a framework solution that can not only address current resource disputes, but also those that may arise in the future.

Our initial proposal would have legally separated the North Dakota portion of our service area into a separate operating company, with pseudo-separation identified as a second best option. Under the legal separation framework, we felt confident we could retain the benefits of economies of scale in our resource planning, yet be able to customize resource portfolios for certain states, to the extent necessary. Pseudo-separation could also prove feasible, if each state agreed to the method by which we would propose to conduct these cost allocations.

In response to this proposal, the North Dakota Staff recommended against legal separation, instead preferring a solution that used a form of proxy pricing to determine appropriate resource cost allocations for resources in the Upper Midwest system. Further, Staff was interested in pursuing the Company's proposal to institute a formal resource planning process in the state, in order to provide the North Dakota Commission with more information about planned resource additions earlier in the process, and to provide the Company more certainty regarding the state's policy objectives and deemed customer needs.

While we do not see proxy pricing as a viable forward-looking solution for reconciling resource treatment, we continue to believe that instituting a formal resource planning process is beneficial and will provide more clarity to the Commission and the Company on what resources may work as system resources. In response to the Commission's request for a more detailed proposal, we submitted a framework outlining essential pieces of a North Dakota Resource Plan, including a default presumption that the system would continue to be planned in an integrated fashion, and a proposed timeline for filing that is consistent with the Minnesota process. We discussed the proposal at an informal hearing with North Dakota Commissioners in March of this year, where the Commission confirmed that it is interested in a more formalized resource planning process.

Currently, we do not recover the full PPA costs of the Aurora, Marshall, and North Star solar PPAs, the Community Based Energy Development (C-BED) PPAs, or the Renewable Development Fund (RDF) PPAs from our North Dakota customers.

3. South Dakota

We have also faced challenges in recovering the costs of certain resources in South Dakota. In December 2016, the South Dakota Public Utilities Commission (SDPUC) suspended the fuel clause adjustment in order to investigate the costs of certain disputed resources recovered through the fuel clause.[22] The Company worked with South Dakota Commission Staff to development a Settlement to address these concerns. In September 2017, the Commission approved a Settlement Stipulation that addressed the costs recovery for the Aurora solar resource and several biomass resources. The Settlement also required the development of proxy prices for several remaining disputed resources, which include the Marshall and North Star solar PPAs, C-BED PPAs, and Renewable Development Fund PPAs. The Company submitted a proxy price proposal to the South Dakota Commission which provided eight potential proxy pricing options for the Commission's consideration and recommends a combination of market-based and index-based pricing, depending on the particular resource.[23] We are engaging in ongoing discussions with South Dakota Staff as we work toward a resolution of these outstanding issues. While we are working to develop proxy prices as a resolution for past resources, when disputes arise in the future we would work to develop a cost allocation mechanism to allocate the costs and benefits of new resources to the participating jurisdictions.

Currently, we do not recover the full PPA costs of the Aurora solar project from our South Dakota customers and we are recovering the costs of the PPAs for the disputed resource subject to refund based on the resolution of the proxy price proceeding.

4. Wisconsin

In Wisconsin, the Company is subject to a Renewable Portfolio Standard (RPS) equal to 12.89 percent of its three-year average in-state retail energy sales. In 2018, excluding renewable energy used for voluntary renewable programs, NSPW provided 24.3 percent of its retail energy sales from RPS-eligible renewable-based energy sources, and the Company is in compliance with its 2018 RPS requirements.[24] This requirement has not changed recently. However, the state's newly elected governor has identified climate objectives as one focus of his administration. In line with these goals, the administration has proposed carbon reduction goals for the state's electric sector that are broadly consistent with our objectives to reduce emissions by 80 percent from 2005 levels by 2030, and 100 percent by 2050. It is not yet clear

[22] *See* South Dakota Docket No. EL16-037.
[23] *See* South Dakota Docket No. EL18-004.
[24] *See* Docket 5-RF-2018 *Renewable Portfolio Compliance Plan for CY 2018. Northern States Power Company, a Wisconsin Corporation.*

whether these proposed goals will result in additional mandates for the electric sector.

5. Michigan

In Michigan, the Company is subject to a Renewable Energy Standard (RES) equal to 15 percent of retail sales by 2021, with a goal of 35 percent renewables and 25 percent energy waste reduction by 2025. We are ahead of schedule on both these goals, already exceeding the 2021 RES requirements and expecting to meet the 2025 goals by 2020.

This year will also be the first time we are required to submit a Resource Plan to the Michigan Public Service Commission, in accordance with Public Act 341 of 2016. Michigan's new Resource Plan process allows us to file the same resource plan in Michigan as we are filing with the Minnesota Commission, and on a similar timeframe, with the understanding that the Michigan Commission may ask for additional supplemental information to help them evaluate the plan as it relates to Michigan.[25] We plan to file this multi-state Resource Plan in Michigan on July 31.

H. Conclusion

We believe our progressive carbon reduction goals are the right path forward for the our customers, our employees, our Company and the State. We are confident in our ability to achieve these goals while maintaining the reliability and affordability our customers count on. This transition, while exciting, is not without challenges. We will continue to navigate significant market and regulatory uncertainty, jurisdictional differences, technology changes and more. That said, we are optimistic that these challenges also present opportunities to engage with customers, regulators, market operators, communities, and employees on our goals in a way that meets multiple stakeholders' objectives.

CHAPTER 3
MINIMUM SYSTEM NEEDS

Our resource planning process focuses on deep carbon reductions while serving our Upper Midwest customers reliably and affordably. In this Chapter, we describe in more detail how we arrived at the minimum amount of resources our system will need through the planning period. The system needs and existing resources evaluated here formulate the baseline upon which we have developed the Reference Case, our modeling scenarios, and ultimately our Preferred Plan.

We have made the following changes to aspects of our Minimum System Needs approach with this Resource Plan:

- *Supply-side Resource Treatment for DSM.* In this Resource Plan we are treating both EE and DR as supply-side resources, rather our previous treatment of EE as an adjustments to future load. Supply-side resources available to the model now include incremental EE and DR in "bundles," or amounts of achievement that we formed from the *Minnesota Energy Efficiency Potential Study* and *Brattle Demand Response Potential Study*, respectively.
- *Reliability Requirement.* We have developed and applied a threshold requirement for firm dispatchable resources. This Requirement is needed to ensure system reliability and resilience until MISO evolves its capacity accreditation construct to better recognize the variability and declining incremental electric load carrying capability of wind and solar resources.

I. MEETING CUSTOMER NEEDS

Forecasting customers' needs for electricity is a key component of any resource plan, and provides the foundation for determining the type and amount of resources that will be needed over the 15 year planning period. The first step is forecasting the amount of electricity our customers will need over the planning period. To this, we add a reserve margin that is prescribed by MISO. We then subtract the resources we already have or expect to have (with some adjustments), to determine our net surplus or need.

We illustrate this concept and discuss each of the components below.

Figure 3-1: Net Resource Need/Surplus Calculation

Customer Needs Forecast
Plus MISO Reserve Margin
Equals **Total Capacity Obligation**
Minus Demand Response Capability
Minus Generation Capacity (measured by UCAP)
Minus Generation Adjustments
Equals **Net Resource Need/Surplus**

A. Customer Needs Forecast

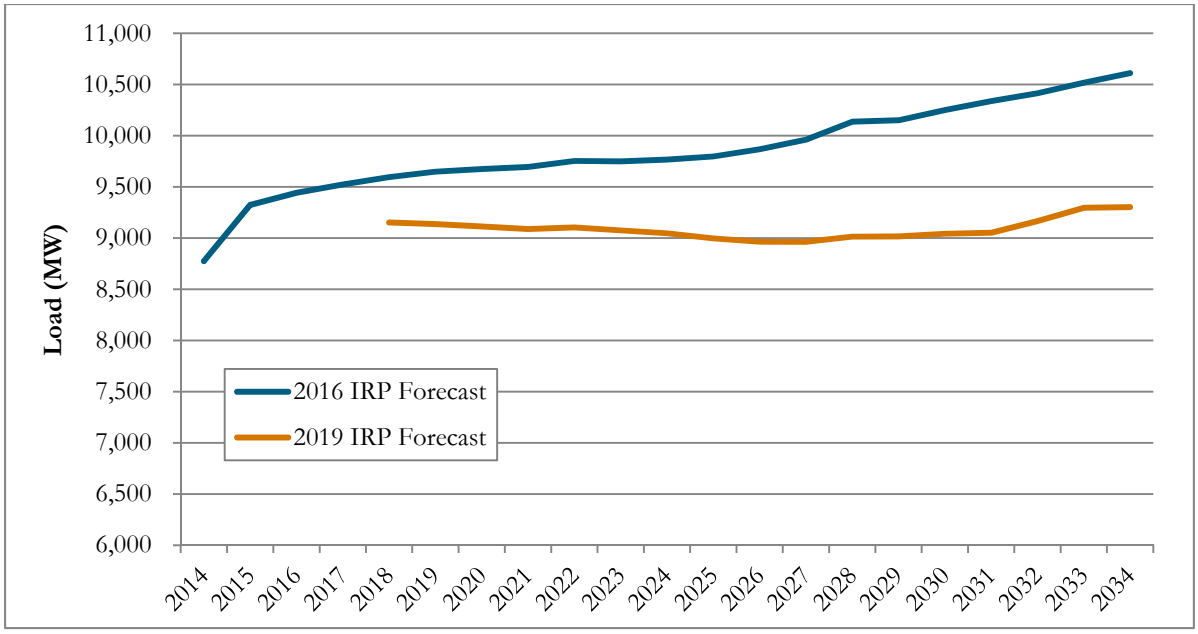
Forecasting our customers' energy needs starts with a capacity, or peak demand, assessment, which informs the total amount of generating capacity (in megawatts, or MW) needed to meet our customers' needs in the highest demand hour (i.e. peak-hour) in each year of the planning period. We also assess the amount of total energy (measured in megawatt hours or MWh) we expect customers to consume in each year of the planning period. Together, the peak demand and total energy needs inform the type of generating resources that will best meet customer needs.

1. Peak Demand Requirements

We use econometric analysis and historical actual coincident net peak demand data to determine system capacity requirements for each year. We provide a detailed discussion about our peak demand forecasting methodology in Appendix F1.

Our current forecast shows essentially flat load relative to current levels, with an average annual growth rate of less than 0.2 percent, after accounting for EE. Figure 3-2 below shows the current forecast in relation to the forecast from our last Resource Plan.

Figure 3-2: Forecasted Peak Load, After Energy Efficiency Adjustments (MW)[1]



We have changed our approach to how we present our peak forecast from our last Resource Plan based on our treatment of EE as a supply-side resource in this Plan. The peak forecast in our previous Resource Plan included both a demand reduction associated with historic EE, as well as from the impact of future incremental EE as approved in the previous Resource Plan.

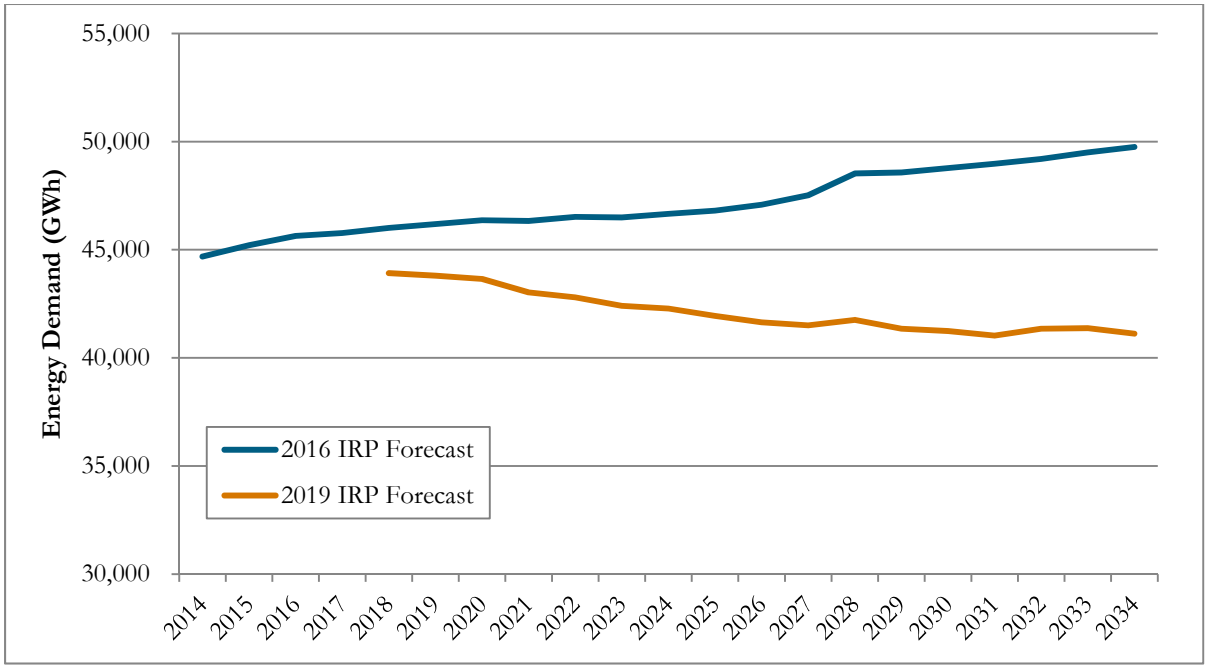
For this Resource Plan, we have changed our approach to addressing EE in two ways. First, the load forecast used in our Strategist modeling no longer has embedded incremental EE, although it is shown in that manner in the charts above for comparison purposes with previous Resource Plans. Instead, we treat EE as a supply-side option that the Strategist model can select in its resource optimization. To do so, we developed EE "Bundles," which we describe in Part III below and in more detail in the Strategist Assumptions Appendix F2. As a result, rather than adjust our peak forecast based on an assumed level of future EE adoption (this would have been 1.5 percent per the level approved in our last Resource Plan), we are reflecting our commitment to *higher* levels of EE achievement (approximately 2.5 percent reduction) in our Reference Case. This level of EE reflected in the Reference Case is representative of two of the EE Bundles available for Strategist to select.

[1] Although we modeled EE bundles as supply-side resources in this Resource Plan, we show the estimated resulting EE as a load reduction from gross load for purposes of the chart above.

2. Energy Requirements

We forecast declining energy needs of approximately 0.4 percent over the 2020-2034 planning period, after accounting for EE included in the Reference Case. As discussed above, the inclusion of two incremental EE Bundles reflects achievement of approximately 2.5 percent EE, which leaves our Net Demand substantially lower than forecast in our last Resource Plan. Figure 3-3 below compares our estimated net energy demand adjusted by the two EE Bundles, to the energy forecast in our last Resource Plan.

Figure 3-3: Forecasted Net Energy Requirements, After Energy Efficiency Adjustments[2] (GWh)



3. Forecast Adjustments

After determining the base peak capacity and energy demand forecasts, we make certain forecast adjustments to account for the impact of events or trends we reasonably expect to occur in the planning period. We summarize our key adjustments below:

DSM. In past Resource Plans, the load forecasts used by Strategist were adjusted for

[2] Although we modeled EE bundles as supply-side resources in this Resource Plan, we show the estimated resulting EE as a demand reduction from gross demand for purposes of the chart above.

the expected effects of existing DSM programs. In this Resource Plan, based on feedback from stakeholders, incremental EE is no longer embedded in the load forecast, rather EE is treated as potential supply-side resource in our modeling, like DR. Both EE and DR are shown as separate line items in our Loads and Resources table below, though in an effort to maintain consistency with Load and Resource reporting between this and previous Resource Plans, we show EE "above the line" as a subtraction from gross load. We further discuss the EE and DR (collectively, DSM) in the context of our resource planning process in Appendix G1.

Distributed and Small Scale Customer Solar Generation. We have historically considered customer adoption of distributed solar (i.e. DG solar as well as CSG) installations as a modification to load in the resource planning process. In this Resource Plan, we have accounted for DG solar including CSG resources as a supply-side resource with assumed adoption levels, as shown in the Loads and Resources calculation below. Reference Case assumptions currently take into account interconnection requests and expectations based on policy-driven programs. However, we also conduct sensitivity testing around potential increased levels of adoption and are working to develop new tools that improve our understanding of how key market drivers will affect customer distributed solar adoption going forward. We note that our methods for projecting distributed solar installations are currently evolving. As our tools and methods mature, we will increasingly incorporate them into both our Resource Plan and IDP processes.

Expected Customer Changes. We also make adjustments to account for known changes in load on our system. These typically reflect expected changes in specific large customers' electricity usage, either as a result of increased behind the meter energy generation (decreasing demand) or increased production activities (increasing demand).

Light Duty Electric Vehicle Adoption. We adjust our residential energy and peak demand forecasts to account for increasing use of plug-in electric vehicle charging. These forecasts are based on expectations around current stock and future adoption (including the effect of financial incentives to facilitate adoption), and the expected electricity consumption per vehicle.

We use standard statistical modeling techniques to reflect these and other potential sources of variation around our expected forecasts. We discuss our forecasting process, inputs, assumptions, adjustments and results in more detail in Appendix F1: Load and Distributed Energy Resource Forecasting.

II. MISO RESOURCE ADEQUACY REQUIREMENTS

MISO prescribes Resource Adequacy (RA) requirements that are intended to help ensure adequate reliability of the bulk electric supply system. MISO's RA process requires load serving entities (LSE) like the Company to maintain resources that exceed their level of demand by a specific margin (planning reserve margin or PRM) to cover potential uncertainty in the availability of resources or level of demand.[3] The RA requirements are fundamental to the resource planning process, and inform the level of capacity we need in our portfolio to adequately serve customers over a long-term planning process. We describe the various aspects of the calculation below, and note that our effective reserve margin is 2.98 percent.

MISO's RA requirements are set based on an annual planning period; the 2018/2019 planning period covers June 1, 2018 through May 31, 2019. Prior to each planning year, MISO determines two different capacity obligations for each LSE; one for the entire MISO footprint as a whole, and one for the Local Resource Zone (LRZ or Zone) where the LSE resides.[4] For any particular planning year, an LSE's PRM is the greater of the LSE's capacity obligation for the MISO footprint or its capacity obligation for its LRZ.

A. MISO Footprint Capacity Obligation

By November 1 prior to a planning period, MISO issues the finalized PRM applicable to all LSEs within its footprint. MISO determines the PRM by performing a technical probabilistic analysis to determine the minimum PRM needed to achieve a Loss of Load Expectation (LOLE) of 0.1 day per year, expressed as a percentage. For example, for the planning year covering June 1, 2018 through May 31, 2019 the overall MISO PRM was 17.1 percent on an installed capacity (ICAP)[5] basis and 8.4 percent on an unforced capacity rating (UCAP) basis.[6] The study also provides

[3] The factors affecting availability and demand include: Planned maintenance, Unplanned or forced outages of generating facilities, Deratings in resource capabilities, Variations in weather, and Load forecasting uncertainty.

[4] Almost all of the NSP system load is located within LRZ 1, which includes almost all of Minnesota, western Wisconsin, and the Dakotas. Approximately 7 MW of load along the Minnesota-Iowa border is located in LRZ 3.

[5] ICAP refers to units' Installed Capacity Rating, which is a capacity accreditation measure based on annual or historical tested generating. The ICAP is the lesser of the generator verification testing capacity or the interconnection service capacity.

[6] UCAP refers to units' Unforced Capacity Rating, which is a function of the unit's installed capacity and its anticipated forced outage rate. A generator's anticipated forced outage rate is typically based on the individual unit's historical performance. UCAP = ICAP x (1 – Forced Outage Rate). *See* "Planning Year 2018-2019 Loss of Load Expectation Study Report" at 5. Available at: https://www.misoenergy.org/api/documents/getbymediaid/80578

forward-looking PRM values, through 2028. Over the planning period MISO examined in the 2018-2019 LOLE study, the UCAP PRM remained relatively constant between 8.3-8.4 percent.

Each LSE is required to have resources sufficient to meet the forecasted demand at the time of MISO's peak demand, plus its PRM margin. MISO's tariff acknowledges a state regulatory body's authority to establish a PRM for LSEs within its jurisdiction, which would override the PRM otherwise determined by MISO. None of the NSP System states have established a PRM separate from MISO.

B. Zonal Capacity Obligation

Additionally, MISO makes an annual determination regarding the amount of capacity required within each of MISO's Zones, called the Local Clearing Requirement (LCR). The LCR is determined as a function of each Zone's Local Reliability Requirement (LRR) and its Capacity Import Limit (CIL). The LRR represents the necessary resource requirement in order for a Zone to achieve an LOLE of 0.1 day per year, without relying on resources outside of the Zone. Each Zone, having a smaller footprint than the overall MISO footprint does not benefit from the same level of peak load diversity as does the larger, more diverse MISO footprint. Thus, it can be expected that a Zone's LLR is greater than the sum of its LSEs' MISO footprint obligations. If a Zone within which an LSE operates has import capacity, however, the resulting LCR is reduced. As a result, LSEs usually plan their minimum system needs based on the MISO-wide PRM rather than the zonal requirement.

For the 2018-2019 planning year, Zone 1 was assigned an LRR of 114.8 percent, which, in capacity terms equates to an LRR of 20.2 GW. However, when accounting for Zone 1's CIL of 4.4 GW, Zone 1's LCR is 15.8 GW. This is less than the MISO footprint PRM of 18.4 GW. Thus, Zone 1's import capabilities allow LSEs within Zone 1, including the Company, to plan to the MISO-wide UCAP PRM of 8.4 percent rather than the higher LRR value.

C. Capacity Obligations Derived From Forecasted Demands

After determining the relevant PRM, each LSE can derive its MISO-wide and zonal capacity obligation from its forecast of peak demand (peak load). While LSEs typically forecast the peak demand for their individual system, the resource adequacy process requires the LSE to also forecast:

- The LSE's demand at the time of the MISO footprint's peak demand (MISO Coincident Peak Demand, or MISO CPD), and

- The LSE's demand at the time of the LRZ's peak demand (Zonal Coincident Peak Demand, or Zonal CPD).

Again, because each LRZ footprint is smaller than the MISO footprint, the LRZ's load diversity is lower than the load diversity of the MISO system, and an LSE's Zonal CPD is equal to or greater than its MISO CPD.

The NSP System CPD factor measures how closely our system peak matches the MISO system peak. A coincidence factor of 95 percent indicates that we expect to experience load levels that are approximately 95 percent of our peak load during times when the total MISO system load is peaking. In other words, the timing of our peak and the MISO peak does not match exactly, so we are able to reduce the amount of reserves we carry as a result. After accounting for the coincidence factor, our effective reserve margin drops from 8.4 percent to 2.98 percent. We illustrate this calculation in Figure 3-4 below.

Figure 3-4: MISO Planning Reserve Margin Calculation – NSP System Planning Year June 1, 2018 to May 31, 2019

$$(95\ percent\ coincidence\ factor)x\ (1 + 8.4\ percent) - 1 = 2.98\ percent\ effective\ reserve\ margin\ for\ NSP$$

Putting these pieces together, we used our effective reserve margin, in combination with our annual load forecasts over the planning period, to determine our overall capacity obligation for the same period. For 2020, this calculation results in the following approximate obligation:

Table 3-1: Capacity Obligation Calculation – 2020 Example

Total Capacity Obligation Component	Value
Forecasted load	9.1 GW
NSP Effective Reserve Margin	x (1+ 2.98%)
NSP Obligation	**= 9.4 GW**

Our estimated obligation for all planning period years can be found in the Load and Resources table in Section VI. below.

D. Capacity Accreditation of Resources

After these obligation levels have been determined, we consider the type of resources

suitable to meet that requirement. MISO's tariff and business practices set forth procedures to enable various types of resources to be used to achieve our RA requirements. While there are different requirements among the various types of resources, common characteristics require resources participate in the annual registration process, requiring annual testing and reporting of capability or reporting of historical output. Each resource must have firm delivery to load, and resources must be available throughout the entire planning period.

Resources used to achieve MISO's RA requirements are referred to as "Planning Resources." Planning Resources include the following sub-types:

- *Capacity Resources*: Physical Generation Resources (i.e. physical assets and purchase agreements), External Resources if located outside of MISO's footprint, and DR Resources participating in MISO's energy and operating reserves market, available during emergencies.
- *Load Modifying Resources*: Behind-the-Meter Generation and DR available during emergencies, which reduces the demand for energy supplies coming from the LSE.
- *Energy Efficiency Resources*: Installed measures on retail customer facilities designed and tested to achieve a permanent reduction in electric energy usage while maintaining a comparable quality of service.

MISO's resource accreditation represents a measure of a resource's reliable contribution to the system's resource adequacy needs. A generator's operation, maintenance, and utilization directly impact the portion of nameplate capacity rating recognized as an accredited resource. Therefore, instead of using installed or nameplate capacity (i.e. ICAP), MISO calculates the unforced capacity value (i.e. UCAP) for each resource to determine its expected contribution to RA. These are calculated differently depending on the resource's dispatchability or variability:

- *Dispatchable generation resources, DR and EE* – MISO assigns a UCAP value for dispatchable generation resources by discounting their installed capacity by an anticipated forced outage rate. Resources where availability depends on other factors are measured differently; for example, MISO has a process to determine the UCAP for DR resources using a documented process of assessing the resource's observed responsiveness and load reduction effectiveness.
- *Variable resources* – MISO assigns variable resources, such as grid-scale solar and wind, a UCAP value that is a function of the individual unit's historical performance during the peak hours of the planning period. Currently, these units are measured on historical performance during the operating hours of

1500 to 1700 in the months of June-August over the three most recent summers. Each site must have one complete historic period of data prior to unit accreditation. If sufficient operating history is not available, MISO assigns a proxy value.

Our modeling selects resources based on their UCAP values, to ensure we maintain adequate capacity on our system over the planning period. Additionally, as discussed below in Section IV, we included a further Reliability Requirement in our planning process to address MISO's evolving processes.

III. DEMAND SIDE MANAGEMENT

DSM programs offer our customers opportunities to lower their energy use and manage their peak demand, in particular through our Conservation Improvement Programs. As noted previously, these programs include both EE and DR. We base our forecasts and potential incremental additions on historic achievements through our programs, as well as external studies about expected and potentially achievable adoption rates.

As previously discussed, we adjusted the customer capacity and energy forecasts in this Resource Plan to distinguish incremental EE from the load forecast. We modeled incremental DR and EE achievements as "Bundles" to be evaluated alongside other resource options. Each Bundle represents a combination of program achievements expected to lead to a certain amount of avoided load or energy per year, at an estimated blended cost.

For EE, these Bundles include measures that work to reduce a customer's overall energy usage throughout the year. The DR Bundles, on the other hand, reflect a customer's commitment to discrete reductions in demand (e.g. on a day when peak load is expected to be high otherwise). These actions are expected to reduce the anticipated annual system peak demand, as well as smooth demand on specific days when weather or other conditions lead to high demand at a certain point in time. In the Order approving our last Resource Plan,[7] the Commission directed that the Company "shall acquire no less than 400 MW of additional DR by 2023." In this Resource Plan, we included one DR Bundle in our modeling for both the Reference Case and Preferred Plan.

We discuss the studies that informed our expected EE and DR levels, our analysis,

[7] *See* E002/RP-15-21 Order Approving Plan with Modifications and Establishing Requirements for Future Resource Plan Filings (January 11, 2017), Order Point 10.

and the changing DSM landscape in more detail in Appendix G1.

IV. RELIABILITY REQUIREMENT

A new planning element we included in this Resource Plan is a Reliability Requirement which, in short, will ensure that we can serve customers with reliable energy every hour of every day.

The need for the Reliability Requirement stems from the inherently variable nature of renewable resources and availability of any time limited resource. Further, as the penetration of these resources increases, their value to meet peak customer needs decreases. Although MISO is beginning to recognize these challenges, its current planning constructs do not yet incorporate any measures to address them. Until MISO determines how best to address these gaps, we believe it is incumbent on us as the utility to take steps to ensure that our system is resilient and that our customers will be reliably served. Fundamentally, we have a responsibility to ensure we have access to a sufficient level of firm dispatchable resources in all grid conditions that can flexibly adapt to variable renewable resource performance to meet our customers' needs.

To develop the Requirement, we analyzed industry insights and data from case studies, including the 2019 polar vortex and normal winter and summer days. From this information, we developed a method determine a threshold level of firm dispatchable resources needed to serve customer loads, that reflects a reasonable level of reliance on MISO resources and DR to meet a portion of the need.

Figure 3-5 below demonstrates the calculation of the Reliability Requirement we applied in our modeling for this Plan.

Figure 3-5: NSP System Reliability Requirement Calculation – 2020 Example

Peak Demand Proxy – 6.4 GW
Minus Firm DR (Winter) Proxy – (0.2) GW
Minus Firm Market Supply Proxy – (0.5) GW

Reliability Requirement - 5.7 GW
(Firm dispatchable resources)

To implement this Requirement, we applied it as a threshold in our Strategist modeling to ensure that our firm dispatchable resources do not fall below this level – even while our Preferred Plan achieves an 80 percent carbon reduction by 2030. In

the 2020-2034 planning period, the Requirement ranges from approximately 5.6 GW early in the planning period, to about 6.0 GW by the end of the planning period. We clarify here, however, that while this concept is essential to include until MISO evolves its capacity accreditation constructs, the Requirement as applied in our modeling has little effect for this Resource Plan. The model does not select any firm dispatchable additions as a direct result of the Reliability Requirement until near the end of the planning period, in 2031. This long runway leaves ample time for MISO and its stakeholders to address this aspect of its planning and provide additional direction.

V. EXISTING RESOURCES

Our current generating resources[8] comprise a diverse portfolio including nuclear, coal, wind, biomass, solar, hydro, natural gas and oil-fueled facilities. Physical generating assets owned by the Company have a net maximum capacity of over 9,500 MW, including 850 MW of wind.[9] In addition to these assets, we maintain PPAs representing a net maximum capacity of over 3,700 MW.[10] Together, these provide over 13,200 MW of generation resources, of which over 4,300 MW[11] is supplied by renewables. A total of over 6,000 MW[12] is supplied by carbon-free resources.

A. Renewable Resources

In total, we currently have over 4,300 MW of renewable capacity serving the NSP System, including:[13]

- Over 2,600 MW of wind
- 840 MW of solar, including community solar programs and grid-scale solar[14]
- 680 MW of hydroelectric power[15]
- 160 MW of biomass and landfill gas

[8] As of July 2019; excludes some resources included in modeling that are expected to be online by the end of 2019.
[9] Maximum capacity represented here reflects capacities included in Strategist modeling. It approximates Net Maximum Capacity, which is defined as the units Gross Maximum Capacity, less any capacity that is used for that unit's station service or auxiliary load.
[10] This total excludes 425 MW of renewable diversity capacity credit from contracts with Manitoba Hydro.
[11] *Id.*
[12] *Id.*
[13] Note: these values are approximate.
[14] Per Docket No. E002/RP-15-21 Order Point 4a (January 11, 2017), our solar acquisitions will exceed the 650 MW through CSG resources or other cost-effective acquisitions. The CSG program is on track to exceed the ordered 650 MW by year ending 2019, per the most recent forecast CSG Monthly Report (filed June 14, 2019) and included in this filing as Appendix N8.
[15] Excluding capacity associated with diversity agreement contracts with Manitoba Hydro.

B. Nuclear

Our Monticello and Prairie Island nuclear plants provide nearly 1,740 MW of clean energy and capacity to our customers and play an important role in achieving our goal of an 80 percent reduction in system carbon emissions by 2030, while maintaining reliability and affordability. The monthly capacity factors of our nuclear facilities are historically 90 percent or higher. Together, our nuclear plants currently provide nearly 30 percent of our energy mix. In terms of production costs (fuel plus O&M), both plants have achieved reductions of more than 20 percent since 2015, with average costs now below $30/MWh.

C. Coal

Our coal fleet includes our Sherco Units 1, 2, and 3 in Becker, Minnesota and the Allen S. King plant in Oak Park Heights, Minnesota. This coal fleet provides almost 2,400 MW of baseload and cycling generating capacity, and supports system reliability. In our last Resource Plan, the Commission approved our proposal to retire Sherco Units 1 and 2 in 2026 and 2023, respectively. These retirements are reflected in our Reference Case discussed below. Our Preferred Plan further proposes to retire the King plant in 2028 and Sherco 3 in 2030, after which coal would no longer be part of our energy mix.

D. Natural Gas (and Oil-Fired) Fleet

Our natural gas fleet consists of both intermediate and peaking generation. We have five owned or contracted intermediate-type generating assets that provide just over 2,400 MW of capacity. We have peaking-type resources located at seven sites, providing another 2,350 MW of capacity. Combined, these facilities provide valuable load following capabilities for our system, cycling as necessary to provide important flexibility to our generation operations and support to our growing renewable resources. Our Reference Case also includes pending and proposed capacity resource additions including MEC as proposed in Docket No. IP6949,E002/PA-18-702, and the Sherco CC that the Commission acknowledged in its Order in our last Resource Plan.[16] These pending resources appear in separate line items in our net resource calculation below.

[16] The Commission approved our proposed schedule to retire Sherco Units 1 and 2, and found that more likely than not there will be a need for approximately 750 MW of intermediate capacity coinciding with the retirement of Sherco Unit 1 in 2026. *See* In the Matter of Xcel Energy's 2016-2030 Integrated Resource Plan, ORDER APPROVING PLAN WITH MODIFICATIONS AND ESTABLISHING REQUIREMENTS FOR FUTURE RESOURCE PLAN FILINGS, Ordering Point Nos. 7 and 8, Docket No. E002/RP-15-21 (January 11, 2017).

VI. NET RESOURCE SURPLUS/DEFICIT

As described above, our forecast of customers' peak demand and MISO Resource Adequacy requirements are used to determine our overall total generating capacity obligation. From this, we deduct our expected load management achievements and UCAP generating capacity of the various resources we have included in our Reference Case to determine our net generation capacity surplus or deficit. We anticipate a net surplus through 2026 and a deficit thereafter.

While the Order also addressed next steps for the replacement generation at Sherco, legislation was passed as part of the 2017 Legislative Session that in summary, allows the Company to proceed with the construction of the replacement unit at Sherco in accordance with the parameters specified in the legislation, and without a Certificate of Need. *See* Laws of Minnesota 2017, chapter 5 – H.F. No. 113, section 1.

[17] In addition to existing and approved resources, those indicated with a * include pending or proposed resources that we have included across all Scenarios, including the Reference Case.

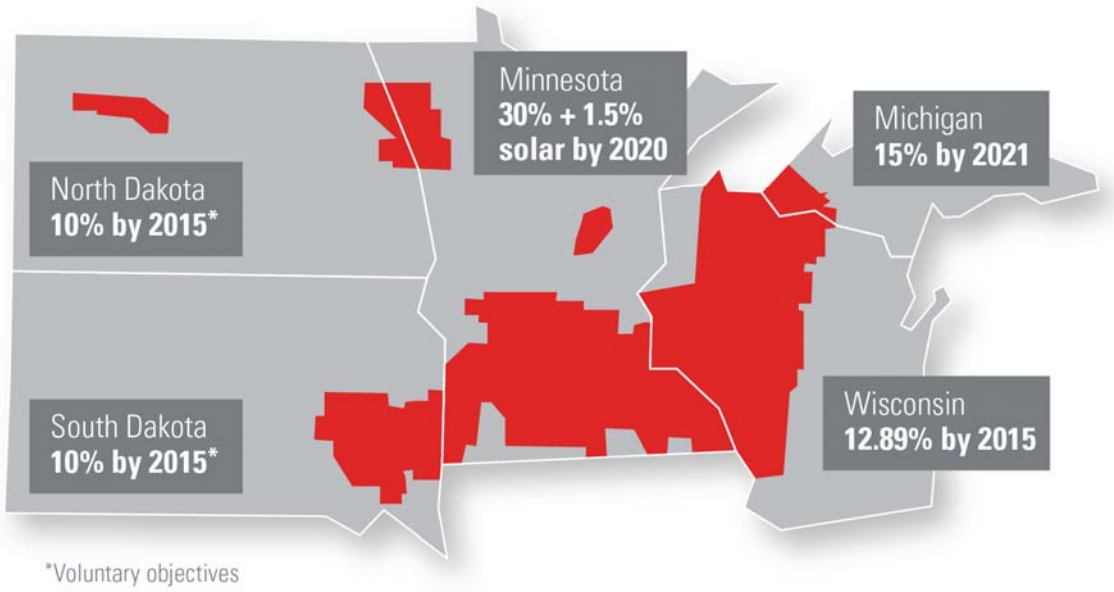
[18] Includes EE savings from historically installed measures, as well as future EE from bundles modeled in this Resource Plan, achieving 2-3% savings levels. Also includes minimal EV and coincidence adjustments.

VII. MEETING RENEWABLE ENERGY REQUIREMENTS AND GOALS

A. Minimum Compliance Requirements

Each of the states in the NSP System has a different public policy with respect to renewable energy requirements or objectives. Figure 3-6 below illustrates each state's renewable energy standard (RES).

Figure 3-6: Renewable Energy Requirements and Objectives – NSP System



Three of our states have renewable standards expressed as a percentage of electric retail sales from qualifying resources by a certain date. Minnesota's RES is the highest, requiring that 30 percent of the Company's energy come from renewables, with at least 24 percent of the electricity we provide to retail customers coming from wind energy by 2020[19] Legislation passed in the 2013 session also established a Solar Energy Standard (SES) for Minnesota that requires that investor-owned utilities in the state generate 1.5 percent of 2020 retail sales, net of customer exclusions, from solar energy resources. Of that 1.5 percent, 10 percent must come from systems with

[19] This requirement is included in the total 30 percent RES, and we are authorized to count a limited amount of solar energy towards an overall 25 percent wind and solar requirement (amounting to 1% of total sales). The SES is assessed separately. Large hydro does not count as a renewable energy source for purpose of the Minnesota RES. Minn. Stat. § 216B.1691.

capacity less than 40 kW.[20] The legislation also established a goal of 10 percent of energy sales from solar by 2030.

North Dakota and South Dakota each have a voluntary objective that includes renewable or recycled energy.[21] Further, our North Dakota regulators have indicated that compliance with the North Dakota Renewable Energy Objective should be accomplished with competitively-priced energy.

To-date we have implemented a strategy to have the entire NSP System comply with, at the very least, the highest of renewable energy requirements across our jurisdictions; in this case, the Minnesota RES. This strategy also places us in compliance with the specific requirements in each of our other jurisdictions. As a result, we have been planning for renewable energy additions, and allocating their benefits, to all of our jurisdictions (with certain exceptions as discussed in the Planning Landscape). As state energy policies continue to evolve, however, we will continue to examine whether this requires a strategy change going forward, and engage our Commissions as needed on that topic.

B. RES Compliance

Given existing and previously approved resources, we project continued compliance with the renewable energy goals and standards in each of our NSP states. The Company currently maintains a set of banked Renewable Energy Credits (RECs) for future compliance.[22] In the past, we have leveraged our REC bank to manage the size, type, and timing of renewable energy additions on our system, to ensure that we identify and acquire the renewable generation resources that provide our customers with the greatest value at the lowest cost. Given our recent focus on adding renewable capacity, however, we now generate RECs in excess of our baseline obligations each year. We currently generate sufficient RECs annually from eligible renewable resources to account for over 40 percent of the energy we provide our NSP System customers, which outpaces our annual requirement

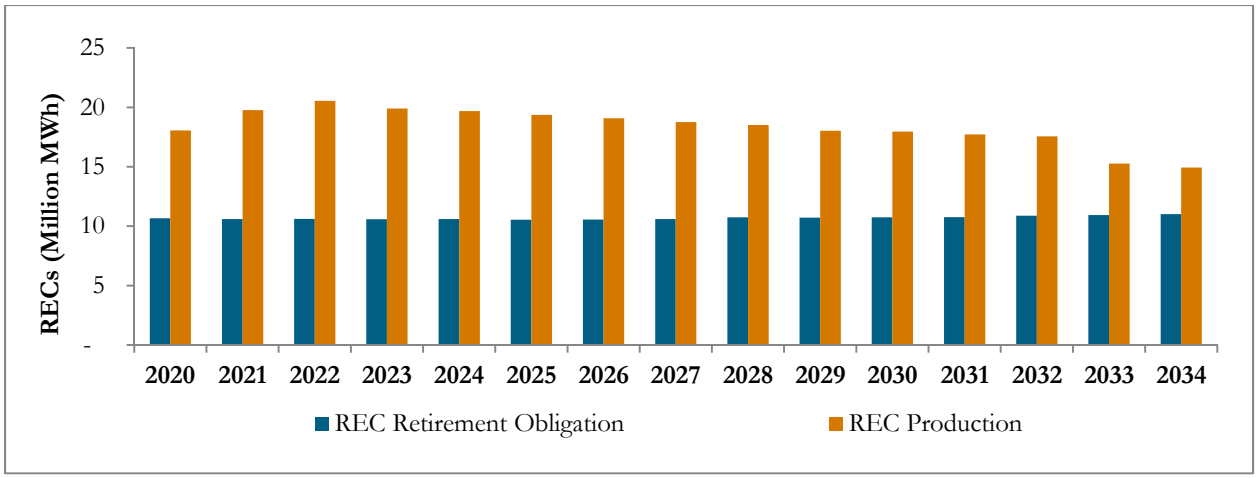
[20] The original legislation set a threshold of 20 kW, but was increased to 40 kW in 2018, per HF3232. *See* "Minnesota Renewable energy Standard: Utility Compliance." Minnesota Department of Commerce (January 2019) at 7. Available at: https://www.leg.state.mn.us/docs/2019/mandated/190330.pdf

[21] As defined in North Dakota Century Code, 49-02-25, recycled energy means "systems producing electricity from currently unused waste heat resulting from combustion or other processes into electricity and which do not use an additional combustion process. The term does not include any system whose primary purpose is the generation of electricity unless the generation system consumes wellhead gas that would otherwise be flared, vented, or wasted." South Dakota Codified Law 49-34A-94 contains a similar definition.

[22] A REC is an accounting device designed to reflect the renewable energy attributes of a particular MWh of renewable energy generation. RECs are the currency for compliance with state renewable targets.

Figure 3-7 below illustrates annually generated RECs across the NSP System in the Reference Case scenario. In this scenario, we will have sufficient RECs to comply with the current renewable energy goals and standards of all of our NSP jurisdictions through 2034, even without securing additional renewable resources.

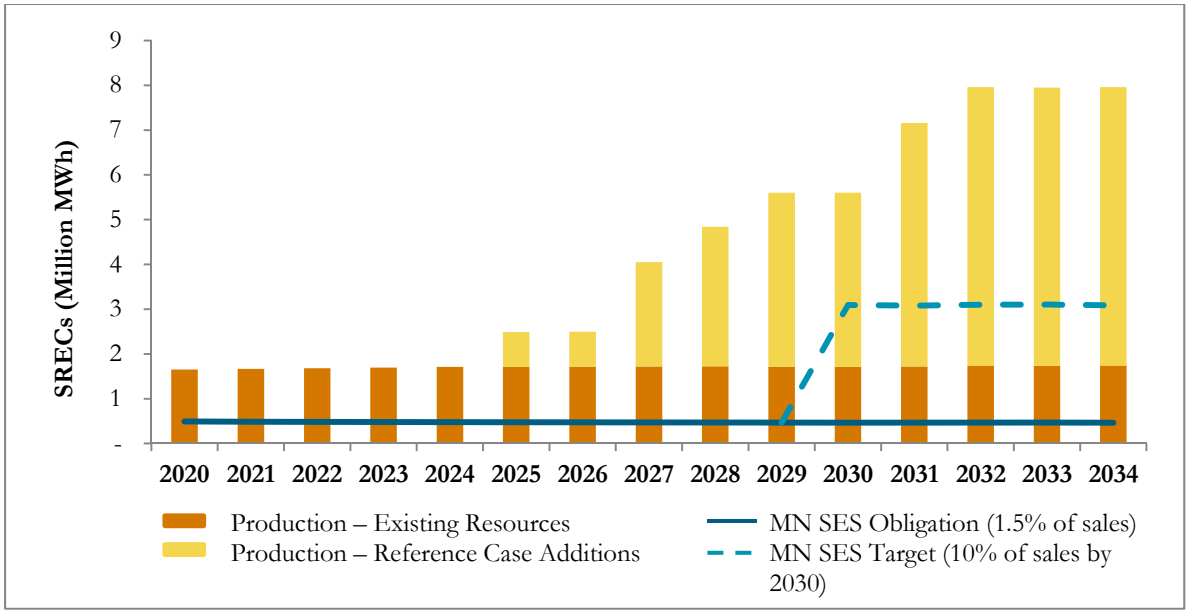
Figure 3-7: REC Production and Retirement Obligations for NSP System – Existing Resources Only



C. SES Compliance

As previously mentioned, Minnesota law requires us to provide our customers with solar-generated energy equal to at least 1.5 percent of our annual customer demand by 2020, and a goal of 10 percent by 2030. We have developed a portfolio of programs to provide solar options to residential and commercial customers, and have also grown our utility-scale solar profile. As a result, we expect to meet the SES requirements through the planning period, per our Reference Case. We also expect the solar capacity additions included in our Reference Case to provide sufficient energy to meet the 10 percent goal by 2030. Figure 3-8 below demonstrates our annual estimated SREC production relative to Minnesota requirements and goals, for the Reference Case scenario.

Figure 3-8: NSP System SREC Production and Minnesota Annual Requirements



We discuss our renewable energy standard compliance further in Appendix N4: Renewable Energy Compliance Positions.

VIII. ENERGY POLICY AND COMPANY GOALS

As demonstrated, we believe that we are well positioned to meet minimum system needs. At least through 2024, we expect that we will be able to meet those needs with existing and already-approved resources. However, in 2018, we committed to an ambitious carbon reduction vision, to achieve 80 percent below 2005 carbon emissions levels by 2030 and 100 percent carbon-free energy by 2050. We are committed to achieving this goal, and as such, have modeled our Reference Case, Preferred Plan, and all other scenarios using our 80 percent carbon reduction target as a guidepost.

IX. REFERENCE CASE

We incorporate all of the aforementioned elements into the Strategist modeling tool, which allows us to explore how we best meet our customer and policy requirements under a variety of conditions and at a reasonable cost. We work with internal and external subject matter experts to develop starting assumptions that reflect their expert opinion of likely future conditions. We then test the robustness of the plans through sensitivity analysis by individually changing key assumptions and re-running

the plans under these changed assumptions. Our analysis resulted in the following Reference Case Expansion Plan, depicted in Tables 3-3 and 3-4 below:

Table 3-3: Reference Case Annual Expansion Plan (UCAP)[23]

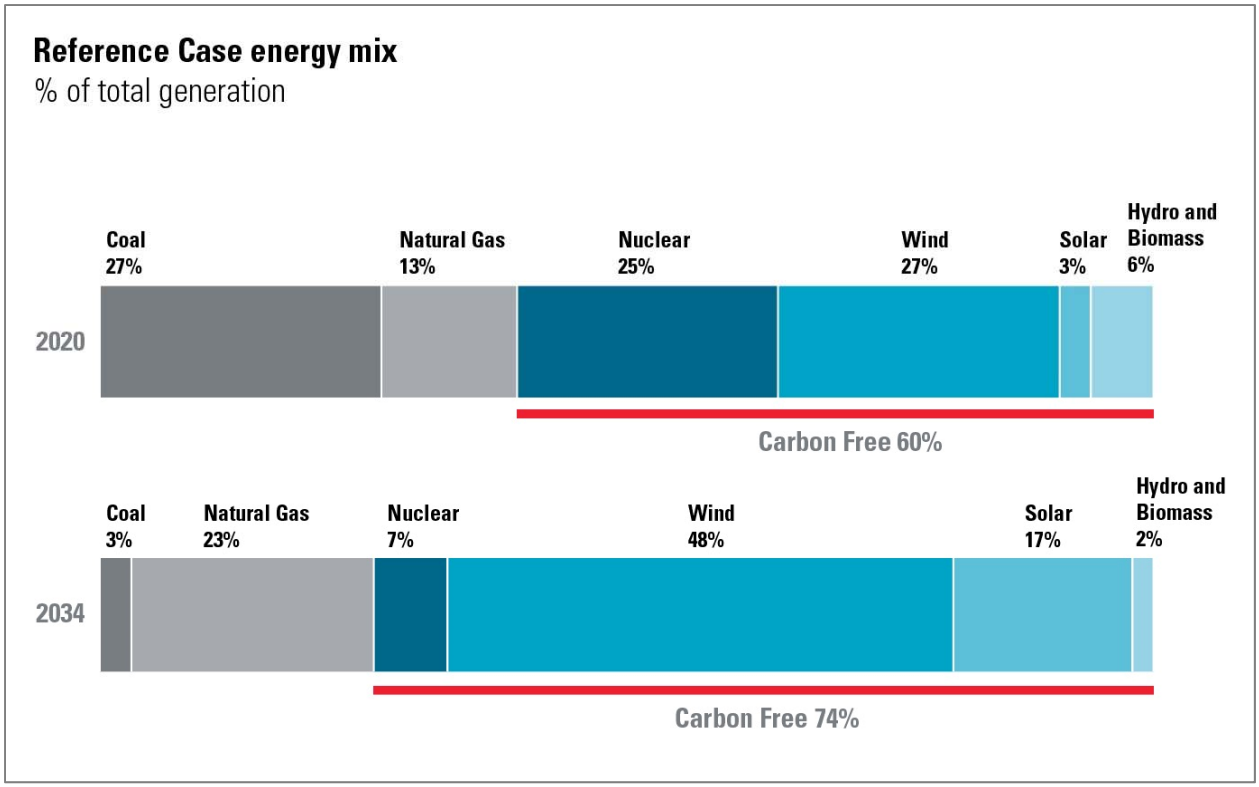
The Reference Case presented here would result in the following energy mix:

[23] Note: This table includes CC, EE, DR, and Distributed Solar resources that are also reflected in the Load and Resources Table.
[24] Note: This table shows ICAP values of the resources indicated in Table 3-4 above.

Figure 3-9: Reference Case Energy Mix in 2020 and 2034



We outline and discuss the starting assumptions, scenarios, and sensitivities that formed our Strategist analysis, and resulted in our Preferred Plan, below and in Appendices F2 and F3.

CHAPTER 4
THE PREFERRED PLAN

The Preferred Plan we propose in this 2020-2034 Upper Midwest Resource Plan reflects extensive collaboration with stakeholders as well as independent expert analysis. It supports our states' clean energy goals and the Company's goal of reducing carbon emissions 80 percent by 2030 – and our ultimate vision of 100 percent carbon-free energy by 2050.

Key components of our Preferred Plan include:

- Retiring nearly 2,400 MW of remaining coal-fired capacity by 2030, including previously approved Sherco 1 and 2 retirements and newly proposed accelerated retirement timelines for Sherco 3 and King. We also plan to implement seasonal dispatch at Sherco 2 prior to its retirement.
- Adding thousands of megawatts of new renewable resources, including substantial solar additions and replacement of expiring wind PPAs.
- Continuing to operate our nuclear plants at least until the end of their licenses, and extending operation of Monticello to 2040, as these resources anchor the grid in around the clock carbon-free energy.
- Significantly increasing our EE and DR resources, which will reduce our overall system demand.

Maintaining grid reliability and resilience through this transformation – as we must – will require firm and dispatchable load supporting resources and potentially significant transmission development. Accordingly, in order to meet reliability needs and support renewable integration as we retire legacy coal units, our Plan includes continued operation of our nuclear units (including a proposed 10-year extension of Monticello), acquisition of the MEC CC, and construction of a CC at Sherco, which we proposed in our last Resource Plan.

At the same time, we believe there may are exciting opportunities to pilot batteries, DER, and other clean, innovative technologies in the Upper Midwest. With respect to DR, in particular, we are seeking the flexibility to evaluate and pursue the required incremental DR through a variety of means and technologies that may go beyond conventional DR.

We have also sought to retain strategic flexibility by deferring decisions on certain generating units such as Prairie Island, which can be addressed in the next planning cycle. Doing so leaves room for innovation and allows for reassessment of

technologies, costs, and capabilities before making substantial investments. It is also consistent with our longstanding belief that a deliberate and well-thought-out fleet transition is critical to facilitating successful community and employee transitions.

Finally, our Preferred Plan comes at a reasonable cost to our customers – with estimated rate impacts that are at, or below, the rate of inflation. In other words, we can achieve industry-leading reduction to CO_2 emissions at a cost that is consistent with the expected national average increase in electricity prices.

In summary, the course we have charted in this Preferred Plan drives toward our goal of achieving significant carbon reductions by 2030 and positions us to deliver on our longer term vision of a carbon-free electricity mix by 2050 – all without sacrificing our ability to deliver the reliable and affordable power that our customers count on every day. In this section we discuss: (1) our primary planning objectives and how they are reflected in our Preferred Plan, (2) the key components of the Plan and the actions we intend to take to achieve it, (3) the estimated customer cost impacts of our Preferred Plan, and (4) how this Plan meets the Commission's public interest objectives. We take each in turn.

I. PLANNING OBJECTIVES

When we began this Resource Plan process more than a year ago, we framed key planning objectives that would set the framework for development of our plan. The objectives are complex. They sometimes overlap and conflict, but each played a critical role in guiding our thinking and analysis which ultimately culminated in a plan that achieves substantial environmental benefits, maintains reliability, keeps costs low, and minimizes risks to our customers.

Figure 4-1: Xcel Energy Integrated Resource Plan Objectives

A. Environmental and Innovation

Environmental benefits and the technological innovations that will help us achieve them are front and center in this Resource Plan process. We have made a bold commitment to achieve 80 percent carbon reduction from 2005 levels by 2030, and have considered this target a modeling pillar for all of our potential scenarios. Our Preferred Plan achieves this goal in several ways. First, our Preferred Plan eliminates coal from our system by 2030, extends our carbon-free Monticello nuclear plant to 2040, adds at least 4,000 MW of new renewable resources, including substantial new solar capacity additions, maintains the wind levels committed to in our previous resource plan, and replaces renewables with renewables when they reach the end of their life.

It is important to note that, because many of these resource additions are not needed for a number of years, maintaining flexibility in how we achieve our carbon goals is essential. We have watched the planning landscape evolve at a remarkable rate over the last decade and we expect the rapid pace of innovation to continue. In fact, we expect technological advancements and innovations will create opportunities that we can seize upon in future procurement processes and integrated resource planning cycles if we retain the flexibility to do so. For example, future technology costs and transmission considerations may influence our mix of wind, solar and other non-emitting resources. Likewise, the need for firm and dispatchable load supporting capacity additions beyond 2030 may be better filled by battery storage and other advanced technology solutions. Where appropriate, we aim to be technology agnostic

and open to what is coming next.

B. Reliability

Our responsibility to ensure a reliable electricity supply for our customers is a fundamental underpinning of our Preferred Plan. We therefore developed a Reliability Requirement that establishes a minimum level of firm dispatchable resources that is required to serve our customers' needs in every hour of every day. The Reliability Requirement was developed through analysis of industry trends and careful study of our system's performance (and the broader MISO system's performance) during both winter and summer days when renewables were unavailable, sometimes for lengthy durations. We discuss the development of the Reliability Requirement in greater detail in Appendix J2.

This Requirement does not drive any resource additions in our Preferred Plan until after 2030. Prior to 2030, our Preferred Plan relies on two primary sources to ensure reliability: (1) the MEC and Sherco CCs and (2) our nuclear units. With respect to the CC units, intermediate gas resources efficiently address reliability challenges because they can vary output to adapt as demand for electricity changes over the course of the day and year. The CC units are large rotating machines, so also provide important grid stability benefits and can also play an important role in our blackstart plans.[1] With respect to nuclear generation, our proposed Monticello extension not only represents a carbon-free workhorse of a resource, it also enhances fuel diversity and provides a generation resource that is not subject to seasonal fuel supply limitations.

C. Cost

Along with leading the clean energy transition and enhancing the customer experience, keeping customer costs low is one of Xcel Energy's central, guiding objectives. Since our last Resource Plan, renewable technology costs – and in particular, solar costs – have continued to decline; we expect this trend to continue going forward. Taking advantage of technological advancements is one reason that we can deliver a Preferred Plan that delivers deep carbon reductions for a nominal customer cost of just over one percent Compound Annual Growth Rate (CAGR) over the planning period. And over the long run, our Preferred Plan is expected to yield net present value savings. In comparison to the Reference Case, which does not

[1] As previously discussed, upcoming generation retirements will impact our current blackstart plans (*i.e.,* our ability to restart the system in the event of a catastrophic failure). While we do not propose any specific action related to the system blackstart at this time, we anticipate addressing this in our next Resource Plan or earlier, if system needs dictate the need to do so.

include accelerated coal retirements or an extension of the Monticello nuclear unit, the Preferred Plan yields $203 million of benefits on present value revenue requirements (PVRR) basis and $461 million of benefits on a present value societal costs (PVSC) basis.

D. Risk and Flexibility

Finally, while holding environmental, reliability, and cost objectives in balance, we also seek to mitigate customer risk by ensuring fuel diversity, maintaining appropriate capacity length in our portfolio, and maintaining flexibility in our plans. Portfolio fuel diversity is essential to risk mitigation – especially so, as we transition away from coal. Incorporating a mix of nuclear, load management, intermediate and peaking natural gas capacity, and renewables into our long-term plans ensures that our portfolio is adequately diverse and mitigates the risk associated with overdependence on any one fuel source. Further, the proposed resource additions identified in our Preferred Plan result in a capacity position that is between 500 to 1,000 MW long in any given year. We believe this modest length is prudent, particularly as we propose to substantially increase renewable resources – adding more than 4,000 MW of incremental new renewable capacity, much of which we anticipate will be grid-scale solar – in addition to our already large wind fleet.

Both MISO and independent analyses suggest that capacity accreditation for solar in particular will decline substantially as more capacity is added. We expect MISO will ultimately recognize this conclusion from its ongoing study of issues associated with integration of high levels of renewables in its planning construct.[2] Therefore, what we believe today to be a long capacity position may actually erode over time.

Maintaining a significant amount of flexibility in our future plans is essential to reliably and affordably navigating the transition of our fleet. To that end, we are deferring a decision on pursuing a license extension at the Prairie Island nuclear plant to subsequent resource plans, thereby preserving flexibility to respond to market conditions at that time. We are also optimistic that the firm dispatchable, load supporting resources needed in the post-2030 timeframe could be provided by new non-emitting technologies rather than traditional gas CTs. In addition, as we look to add solar resources to meet capacity needs in the mid to late 2020s, we are also open to allowing other resource types to compete, to ensure that we secure the most cost-effective resource solutions for our customers. As the industry and technology

[2] We discuss MISO's *Renewable Integration Impact Assessment* (RIIA) in more detail in our Baseload Study, provided as Appendix J1.

continue to rapidly evolve we will evaluate opportunities to bring these potential alternative solutions onto our grid.

E. Our Employees and Communities

Underscoring all four of our objectives is our commitment to our employees and the communities within which we operate. We do not make plant closure decisions lightly, and we are committed to supporting our employees at the Sherco and King plants as we prepare to retire these facilities. In the past we have provided career support services to our employees facing plant closures, and we expect to continue providing this support in the future. We also know that the Company is a major presence in terms of employment and local tax revenues in Becker and Oak Park Heights and the surrounding areas. We also have partners at our Sherco site with Liberty Paper and SMMPA (Southern Minnesota Municipal Power Agency). We are currently participating, alongside Minnesota Power, in a Host Community Impact study, to better understand the potential impact of power plant retirements on host communities. A similar study helped inform our work with the communities surrounding our Sherco 1 and 2 Units, and their planned closure as approved in our last Resource Plan. Since that time, we have worked with Becker and Sherburne County, as well as existing and prospective customers to spur economic development in the area, which also includes our plans to build, own, and operate the Sherco CC. As discussed in Appendix O1: Summary of IRP Stakeholder Engagement, we are committed to continue to work with our employees and communities to navigate this transition together.

II. THE PREFERRED PLAN

Our Preferred Plan is the product of an unprecedented stakeholder process that included 13 public workshops, independent expert analysis, and months of analysis and information sharing. As a result of those efforts – as well as the significant engagement of our stakeholder community over the past year, our Preferred Plan is the product of an unusual amount of consensus this early in the Resource Plan process.

Significant consensus has emerged around the following components of our Preferred Plan:

- Elimination of coal-fired generation from our system by 2030,
- Reduced, seasonal dispatch of Sherco Unit 2 until its retirement in 2023,
- Acquisition of at least 3,000 MW of utility-scale solar by 2030,

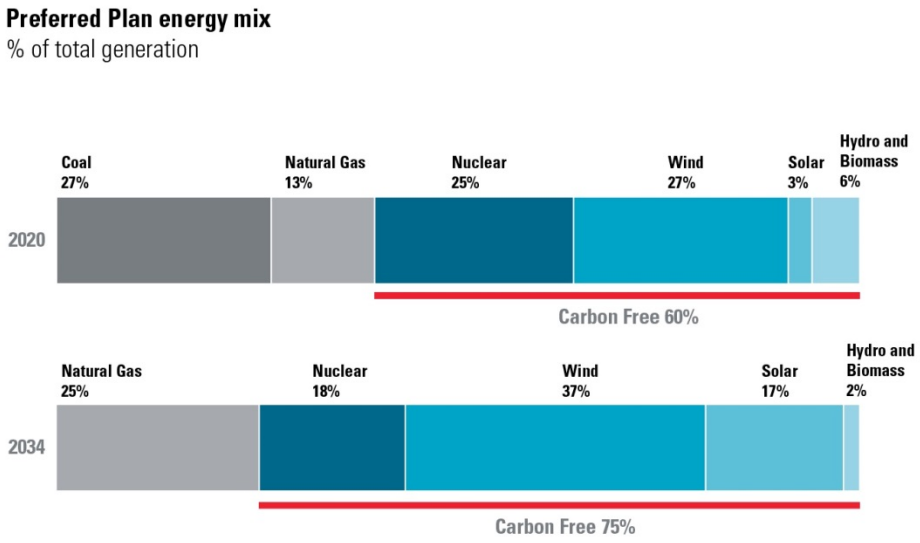
- A substantial increase in EE savings, and
- Support for the Company's proposal to take ownership of the MEC.

Our Preferred Plan builds upon this foundation and includes even more renewable resources, additional DR resources, continued operation of our carbon-free Monticello nuclear plant for an additional 10 years, and a new CC at our Sherco site. In the balance of this section, we present the change in our Energy Mix that will result from our Preferred Plan, and discuss key aspects of the transition below.

A. Transforming Our Energy Mix

From an energy mix perspective, the Preferred Plan eliminates the coal energy contribution and increases the renewable energy contribution by over 20 percent by 2034, rising to approximately 56 percent.

Figure 4-2: Preferred Plan Energy Mix



The fleet transformation underlying our Preferred Plan achieves a nearly 84 percent reduction in CO_2 emissions from 2005 levels by 2030, and maintains at least an 80 percent CO2 reduction through 2034.

Table 4-1 below presents the amount and timing of the resource additions that comprise our Preferred Plan.

Table 4-1: Preferred Plan Resource Additions (MW)

	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034

In the next section, we discuss key aspects of our Preferred Plan and our fleet transition in more detail.

B. Fleet Transition

Our 2020-2034 Resource Plan represents a progressive step forward in transitioning our fleet – meaning that the Company will complete its transition away from coal-fired generation in 2030 – a full decade earlier than previously anticipated. In total, we plan to retire approximately 2,400 MW of coal-fired generation in the next decade. This will be an unprecedented period of transition for our system that necessitates a prudent replacement strategy. Our strategy for replacing this capacity includes a significant amount of additional renewable generation supported by natural gas CC resources, continued reliance on nuclear generation, and large EE and DR additions during the planning period.

1. Renewable Resources

Substantial renewable additions are a central component of our energy future and a cornerstone of this Preferred Plan. Although the quantities of future wind and solar additions may shift somewhat in concert with technology and market fluctuations, our commitment to renewable energy will not. In total, our Preferred Plan envisions a system that is approaching 60 percent renewable in 2034. High levels of renewables combined with cost-effective gas and nuclear generation will combine to create a safe and reliable system that will withstand the summer and winter extremes of the Upper Midwest. Our Preferred Plan proposes to add at least 4,000 MW of cumulative utility-scale resources by 2034 (the first being in 2025) and approximately 1,200 MW of wind by 2034, to replace wind that would otherwise retire from our system during that period.

With these additions, there would be enough solar generation to power more than 650,000 homes each year. Wind generation also continues to play a prominent role in this Preferred Plan. Xcel Energy has long been one of the nation's leading providers of wind energy, and we are currently engaged in the largest build-out of new wind resources in our Company's history – thanks in large part to the Commission's approval of our last resource plan and our 1,850 MW wind portfolio. By 2034, wind will provide 37 percent of the electricity for our customers in this region, making it the largest component of our overall generation portfolio.

2. Coal Resources

Large coal-based generating units have been an important baseload resource to stable grid operations for many decades. As we and other utilities move away from coal for economic, environmental and public policy reasons, we must do so with the maintenance of a resilient and reliable grid at the forefront of our minds.

In our most recent Resource Plan, the Commission approved our proposal to retire our Sherco Units 1 and 2 in 2026 and 2023, respectively. Our proposal to retire these units early was informed by technical analyses that also determined the Sherco CC included in this Preferred Plan is essential to mitigate grid issues. Similarly, our proposal in this Resource Plan to retire our remaining two coals units early – King in 2028 (nine years early), and Sherco 3 in 2030 (ten years early) – is informed by technical and other analyses discussed in our Baseload Study, provided as Appendix J1. As also described in the Economic Modeling Framework Chapter of this Resource Plan, we have included estimated grid reliability mitigation costs into our Strategist modeling underlying the Preferred Plan.

Finally, our Preferred Plan also includes a commitment to offer Sherco Unit 2 into MISO on a seasonal basis until its retirement in 2023 and Commission consideration.

3. Nuclear Resources

Our Preferred Plan proposes to operate our Monticello nuclear unit through 2040 (10 years longer than its current license), and continued operation of both of our Prairie Island units through the end of their current licenses (PI Unit 1 to 2033 and PI Unit 2 to 2034).[3] Nuclear is central to achieving our carbon reduction goals while incorporating incremental renewables at a reasonable pace and maintaining reliability.

[3] Given that our operating licenses for Prairie Island run until 2033 and 2034, we believe there is sufficient time to address the future of that plant in upcoming resource plans.

Nuclear is also an important system resource during the winter months, as it does not experience fuel supply issues and has a great track record during cold weather events – making it a critical component of our reliability strategy. Finally, the continued operation of Monticello contributes to the affordability of our plan by leveraging an existing, high-performing asset on our system. We discuss the benefits of nuclear, as well as the performance of our nuclear fleet, in greater detail in Appendix K.

4. Combined Cycle Resources

In addition to our carbon-free nuclear baseload, the continuation of dispatchable generation on our system will be vital to our ability to manage the retirement of approximately 2,400 MW of coal-fired generation over the next decade while maintaining reliability. It will also facilitate our ability to successfully integrate large amounts of renewables, because we can ramp the output of these resources up or down in response to our system's changing needs throughout the day as renewable resources generate more or less due to their variable nature. To that end, our Preferred Plan includes our proposed acquisition of MEC,[4] which is a 760 MW two-unit CC, as well as our plan to build the approximately 800 MW Sherco CC located in Becker, Minnesota in the mid-2020s.

As discussed in the pending MEC docket, that plant is already an integral part of our system, as its output is committed to the Company through two Commission-approved PPAs. By securing ownership of the plant, we can mitigate the risk associated with expiration of the first PPA in 2026, thereby achieving additional certainty with respect to capacity and dispatchable energy. As discussed in our last Resource Plan, siting a CC at the existing Sherco site will cost-effectively address grid issues identified by the MISO Attachment Y2 study of the Sherco Unit 1 and 2 retirements. Additionally, the Sherco CC will primarily offset the retirement of other gas units on our system, including the Cottage Grove facility (approximately 250 MW in 2027) and Black Dog 5 (approximately 300 MW in 2032). Replacing this capacity is not only reasonable but operationally necessary in light of the much larger coal retirements planned and the large amounts of variable renewable additions we anticipate in the same period. The Sherco CC will also mitigate impacts to the local community and our employees, and potentially provide improved access to natural gas supplies for communities in Central Minnesota. We discuss the Sherco CC further in Appendix L.

[4] As proposed in Docket No. IP6949,E002/PA-18-702. We will incorporate any Commission decision from that docket into our modeling and supplement the record as necessary.

5. Firm and Dispatchable Load Supporting Resources

Reliability is central to resource planning. We are particularly focused on the reliability of our system in this Resource Plan, however, as we embark on a complete transformation of our baseload fleet, and transition to a portfolio of variable renewables that approaches 60 percent of our overall generation. Our transition to cleaner energy will only be successful if we can execute our vision without disrupting our customers' lives and businesses by ensuring a resilient grid that enables us to meet our obligation to provide reliable service.

To this end, our Preferred Plan proposes to begin adding approximately 1,700 MW of cumulative firm dispatchable, load-supporting resources in the 2031 to 2034 timeframe. The need for these dispatchable resources emerges in this later timeframe due to the major plant retirements already discussed, as well as the expiration of several PPAs. Our reliability analysis underlying this Resource Plan demonstrates that these additions are necessary to continue to support grid reliability and resiliency in light of the increased renewables being added to the system and the baseload units being retired.

That said, because these units are not needed until the out-years of our current plan, we have not identified a specific resource type to meet this need. With the expected price declines and technology development between now and the 2030s, we believe storage will be an integral resource used to meet this need. Likewise, we believe the deployment of advanced grid investments could position DR to better compete with traditional generation for this purpose. We are committed to pursuing all of these options not only in the longer term, but also in the near-term in order to leverage this technology as it matures. Generally, by keeping options open and remaining technology agnostic, we can acknowledge the need for a firm resource at the tail end of our plan, but allow the market to advance as we submit future Resource Plans, continue to collaborate with our stakeholders, and engage with the Commission as the need for these resources begins to materialize.

In the meantime, we are analyzing potential locations and sizing of storage solutions as well as the potential values storage assets might provide to the system.

6. Energy Efficiency and Demand Response

Demand Side Management (DSM, which collectively is EE and DR) resources empower our customers to control their energy usage and their monthly electric bills. Load control DR programs are an important part of our resource mix as they can be used during periods of peak demand, helping maintain system reliability. EE reduces

the consumption of energy all together, which has both system and environmental benefits. Taken together, DSM resources are an important part of maintaining system reliability as well reaching our environmental goals.

The DSM aspects of our Preferred Plan includes average annual energy savings of over 780 GWh in each of 2020-2034, compared to average annual energy savings of 444 GWh in our last Resource Plan. In addition, our Preferred Plan also incorporates an incremental 400 MW of DR by 2023 and grows to over 1,500 MW total by the end of the planning period. Importantly, this Resource Plan also signals a change in how we approach EE. In previous plans, we have treated EE as a reduction to customer load. In this Resource Plan, EE is considered a supply-side resource that the economic modeling considers alongside other resource types.

In our last Resource Plan, the Commission approved 1.5 percent annual EE savings on a go-forward basis. The level of EE we propose in this Plan is based on the 2018 *Minnesota Energy Efficiency Potential Study,* and proposes to achieve savings levels ranging from approximately two percent to 2.5 percent annually. This level of EE achieves more than 800 MW of additional demand savings by 2034 compared to the 1.5 percent level approved in our last Resource Plan.

Finally, consistent with the Commission's Order in our last Resource Plan, our Preferred Plan proposes to add 400 MW of incremental DR by 2023, and grows our total portfolio to over 1,500 MW total by the end of the planning period. When it comes to DR, the Company leads the way in MISO, with 830 MW registered in the current planning year. In our last Resource Plan, the Commission ordered the addition of 400 MW of incremental DR by 2023. As we understood the Commission's reasoning, it sought to add incremental, cost effective DR to avoid near-term reliance on additional combustion turbines (CTs). As can be seen in our analysis, however, no CTs or other firm, dispatchable resource additions are required until the 2031 timeframe as the model instead prefers solar additions in the 2025-2030 timeframe.

That said, we decided to include the DR in our Preferred Plan for several reasons: (1) to be consistent with the Commission's Order in our last Resource Plan, (2) to fill gaps if/when the solar capacity credit declines, (3) to help meet firm dispatchable resource needs in the 2030s, (4) to help support customer programs, and (5) to integrate new and emerging technology and tools. We note that for purposes of our modeling, we have included all of the DR identified in the Brattle study as cost-effective, including expansions to conventional DR programs (i.e., Savers Switch, smart thermostats, and interruptible rates) and a non-conventional smart electric water heater program. Additionally, we included the addition of Auto DR, another

non-conventional DR program that automates control of various end-uses like HVAC and lighting.

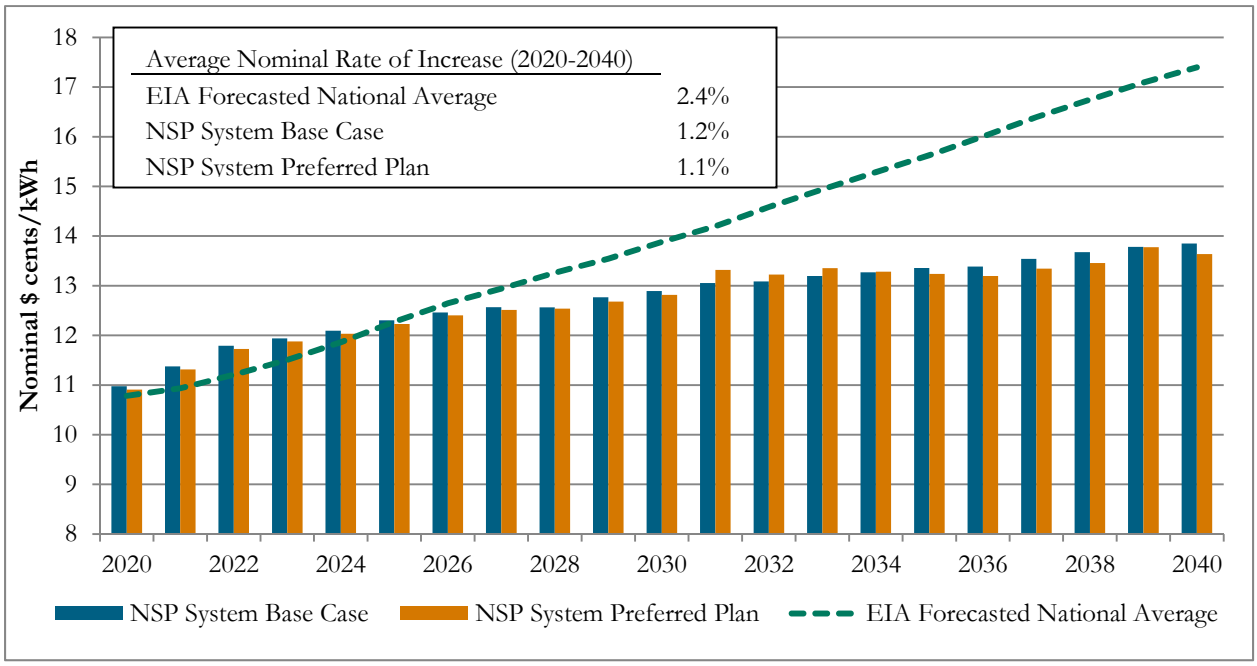
We believe the advancement of our grid, and technology generally, may take the form of less traditional DR, so with this Resource Plan we are requesting the flexibility to evaluate and pursue the required incremental DR through a variety of means and technologies over the coming years. Our objective with this resource type is to bring forward information on several viable options so the Commission, stakeholders, and the Company can engage in an informed exchange. We provide an analysis and detailed discussion of EE and DR in Appendix G1. We also discuss how we applied EE and DR as supply-side resources in our Strategist modeling in Chapter 5. Economic Modeling Framework.

C. Keeping Rates Affordable for Customers

Our Preferred Plan keeps annual cost growth at or below the rate of inflation. In other words, we can achieve significant CO_2 emissions reductions, with cost impacts that are roughly consistent with the expected national average increase in electricity prices.

To show the cost impact of our Preferred Plan over the long-term, we provide as Figure 4-3 below, a CAGR comparison to the national average nominal cost CAGR.

Figure 4-3: Preferred Plan Average Nominal Cost Comparison (NSP System)



* *Notes: National energy cost forecast from Energy Information Administration (EIA) Annual Energy Outlook 2019, Table Energy Supply, Disposition, Prices and Emissions – Reference Case. End use prices, all sector average.*[5] The Preferred Plan and Reference Plan lines include the costs of Solar Rewards*Community.

We derived this long-term projection using a combination of a shorter-range financial forecast and the Strategist model. The modest cost increase associated with our plan is attributable, in large part, to our strategy of deferring resource additions until later in the plan and making use of existing assets on our system. We believe technological improvements will continue to drive the costs of renewables down, which is a key driver in our strategy of proposing significant solar additions in the latter half of the next decade.

We provide our full analysis and discussion regarding customer cost and rate impacts in Chapter 6: Customer Cost and Rate Impacts.

[5] *See* https://www.eia.gov/outlooks/aeo/data/browser/#/?id=8-AEO2019&region=0-0&cases=ref2019&start=2017&end=2050&f=A&linechart=~ref2019-d111618a.70-8-AEO2019&ctype=linechart&sid=ref2015-d021915a.70-8-AEO2015~ref2019-d111618a.70-8-AEO2019&sourcekey=0 The EIA's Annual Energy Outlook was published in January 2019. The report is available at https://www.eia.gov/outlooks/aeo/pdf/aeo2019.pdf.

In the next section, we discuss the actions we plan to take over the next five years, and in the longer term, to achieve our Preferred Plan and deliver on our goals to achieve deep carbon reductions in our electricity mix.

III. ACTION PLANS

A. Five-Year Plan

Our Preferred Plan does not identify any incremental capacity needs through 2024. Thus, our actions in the next five years primarily address previously approved or pending resource additions and retirements, wind repowering and procurement to meet specific customer needs, and continuing to achieve reductions in energy demand and load through ambitious DSM programs. We also plan to make targeted investments in supporting infrastructure to accommodate increased renewable energy and DER on the grid, and to gain operational experience with technologies that may play a larger role on our grid in the future.

Wind. We expect that the 1,850 MW of wind generation resulting from our recent acquisitions and RFPs will achieve commercial operation by 2022. These additions were assumed across all of our scenario analyses. Further, we expect to replace the approximately 170 MW of wind capacity that will expire in the next five years. We are committed to pursuing repowering and/or contract extension opportunities for this capacity, as part of our "no going back" renewables strategy. Further, we intend to pursue incremental renewable resources as needed to meet customer needs in growing customer programs like Renewable*Connect.

Solar. Our Preferred Plan includes significant amounts of large scale solar resources. However, the initial planned addition of 500 MW does not occur until 2025, which is just outside of our five-year Action Plan window. In order to procure this initial tranche of solar, we expect to implement a competitive acquisition process in the 2023 to 2024 timeframe. We expect this timeline will allow us sufficient lead time to acquire these solar resources and bring them online by the end of 2025.

On the distributed solar side, we have included forecasted growth in our plan. If actual distributed solar capacity additions exceed our expectations, we anticipate this will simply displace a portion of our proposed utility-scale solar resources.

Hydro. We anticipate adding 125 MW of energy and capacity through a PPA with Manitoba Hydro in 2021. This incremental contract with Manitoba Hydro is in addition to our existing PPA and diversity exchange and was executed in 2010.

Nuclear. Our Preferred Plan includes a request to operate our Monticello nuclear unit for an additional 10 years beyond its current license. While the license does not end until 2030, we expect to begin a Certificate of Need proceeding with the Commission within the next five years. We also expect to begin working toward license extension with the NRC during this timeframe.

Natural Gas/Oil Peaking. We anticipate extending the life of Blue Lake Units 1-4 through 2020-2023,[6] which provides 153 MW of peaking capacity to the NSP System. Our Preferred Plan further includes our acquisition of MEC, which is currently pending Commission consideration. Finally, we plan to continue development activities associated with the Sherco CC during the next five years.

In addition, as discussed in our last Resource Plan, system retirements will impact our current blackstart plans and we are currently analyzing our blackstart path to determine the best fit for our system needs. While we do not propose any action related to the system blackstart at this time, we anticipate addressing this in our next Resource Plan or earlier, if system needs dictate the need to do so.

Coal. As approved in our last Resource Plan, we will take action with MISO and retire Sherco Unit 2 in 2023, and intend to offer it into MISO on a seasonal basis until that time. Though outside the five-year action window, we are proposing to retire the remainder of our coal units (Sherco 1, Sherco 3 and King) before 2030. As with our previous plant retirements, we plan to begin working with our employees and host communities to prepare for this transition.

Demand Response. Our Preferred Plan proposes to acquire 400 MW of DR resources by 2023, which we intend to evaluate and pursue through a variety of means and technologies over the coming years.

Supporting infrastructure. Aside from the grid-scale and DER additions included in our Plan, sufficient supporting infrastructure is essential to facilitate our fleet transformation, ensure grid resilience and reliability, and to enable greater DER and DR resources on our system. For example, we anticipate completing transmission investments, such as the Huntly-Wilmarth project, in late 2021. We expect further and substantial transmission infrastructure development will be necessary over the long-term, which will involve planning in the near-term. We also are continuing to refine our advanced grid strategy and intend to propose implementation of foundational grid modernization investments – and continue our work to integrate

[6] Pending decision in Docket E,G002/D-19-161

planning processes at all levels of the grid.

Gaining technology experience. As discussed above, we know that energy storage will be essential for our future grid, in order to integrate variable renewable energy without the use of traditional firm dispatchable generation. In the near term, we plan to take steps to gain additional experience with energy storage in the NSP system. For instance, we are co-investing in a microgrid project with Fort McCoy in the NSPW system that will pair solar with storage as a resiliency solution, supplementing traditional diesel backup generators. This project, slated to come online in 2021, will not only support resiliency at Fort McCoy, but will also help us gain valuable experience in maintaining and operating an energy storage facility, especially in the context of new market guidelines in MISO. We anticipate that it will produce income streams to the benefit of all customers through energy price arbitrage, ancillary services, and using the battery as a capacity resource.

Resource treatment across states. We continue to explore options with the North Dakota Public Service Commission to create a resource planning process that can more formally accommodate generation portfolio preferences. We believe additional discussions with all of our state Commissions will be necessary during the five-year action planning period to address differing energy policies and changes in cost allocations that may result.

B. Long-Term Plan

By 2025 we expect we will have achieved approximately 60 percent CO_2 reduction from 2005 levels, per the measures highlighted in our Preferred Plan. In the 2025 and beyond timeframe, there are several key aspects of our system that we will need to address to ensure we can achieve both our 2030 carbon reduction goals, and ultimately, our longer term goals to achieve 100 percent carbon-free electricity. For instance, we anticipate that increasing levels of variable renewable energy and additional baseload unit retirements will necessarily affect the way MISO plans for the broader grid in the future. Notwithstanding the rapid pace of change occurring in our industry, there are several action items on our long-term planning horizon.

New Transmission Infrastructure. Increasing renewable energy on the broader MISO grid is nearly a certainty; wind and solar projects make up over 85 percent of proposed capacity currently in the MISO generator interconnection queue.[7] However, as noted

[7] MISO "Generator Interconnection: Overview." Updated as of June 1, 2019, at: https://cdn.misoenergy.org/GIQ%20Web%20Overview272899.pdf

previously, the queue process is mired with delays and high interconnection cost estimates, in large part due to a lack of available transmission capacity. While generator replacement processes will help us place renewables on our system using existing interconnection rights to an extent, we will need more transmission capacity to come online to effectively achieve the level of renewables we envision on our system – and more broadly within MISO – by 2030 and beyond.

Increasing energy storage on our system. As previously noted we expect that battery energy storage system costs have room to decline over the next several years. We also know that, as variable renewable adoption on the grid increases and more baseload capacity comes offline, we will need a mix of low and non-emitting technologies that can address renewable variability and ensure reliability cost effectively for customers. Battery energy storage holds substantial promise for meeting these needs, and given expected cost declines, we anticipate that we will be able to install cost effective energy storage on the NSP System in the future.

Prairie Island. Our Preferred Plan continues the operation of both Units to the end of their current operating licenses – 2033 for Unit 1 and 2034 for Unit 2. Our baseload scenario modeling results presented in the next Chapter show that there may be value in extending the life of this plant. However, given our operating licenses extend nearly to the end of the planning period, we do not yet need to begin pursuing relicensing. Therefore, we plan to continue working with our stakeholders and evaluate Prairie Island in the context of our future system in subsequent resource planning cycles, rather than locking into a decision at this time. In the meantime, however, Prairie Island continues to serve an important function on the grid and in providing cost-effective and carbon-free baseload power through the planning period.

North Dakota CT. As discussed further in Part IV below, the Company agreed to take steps to locate a natural gas CT in the state of North Dakota, to be operational by December 31, 2025. We remain committed to locating more generation in North Dakota in the future, and we expect to address this resource in our next Resource Plan.

Meeting Statewide Statutory Environmental Goals. Minnesota's Next Generation Energy Act contains a goal for statewide carbon reductions of 80 percent (from 2005 levels) by 2050. While the statewide goal is for all sectors, the Preferred Plan we propose in this Resource Plan achieves over 80 percent reduction by 2030. We know that the electric sector has a unique role to play in achieving the statewide goals. E3's Minnesota PATHWAYS Report, included as Appendix P3, indicates that reducing carbon emissions in the electricity sector enables beneficial electrification to further mitigate emissions in other sectors – in particular the transportation and building

sectors. As we discuss in this Resource Plan, our path to achieving 80 percent carbon reduction from 2005 levels in our system relies on retiring baseload coal units, increasing renewable energy, extending nuclear operating licenses, and implementing incremental DSM, and including energy storage. To be sure, all electric utility systems are different and will encounter different challenges on their path to carbon reduction – and there remain challenges to maintaining that level of carbon reduction if current barriers (e.g. transmission constraints or lack of cost effective long-duration storage options) are not mitigated. However, the analysis findings that led us to our current Preferred Plan give us confidence that the electric sector as a whole can help achieve Minnesota's 80 percent carbon reduction by 2050 goal. We further discuss our outlook regarding this statewide goal and potential barriers in Appendix H.

Meeting Company Goals to Achieve 100 Percent Carbon Free Electricity by 2050. As noted throughout this Resource Plan, our Preferred Plan charts a path toward achieving our 2030 carbon reduction goals, and positions us to address our longer term vision of achieving 100 percent carbon-free electricity by 2050. This goal, however, is not one we can achieve cost-effectively or reliably without substantial technological breakthroughs. This includes, in particular, carbon-free dispatchable energy resources that will help us balance variable renewables' output relative to customer demand. Significant research and development is required to bring potential new technologies to commercialization stage; these could include solutions such as longer-duration battery energy storage, other types of energy storage, hydrogen-fired generation, advanced nuclear technologies, carbon capture and storage, and others.[8] We continue to monitor potential emerging technologies and are excited to see what applications will emerge to help make our vision a reality in the long term.

IV. NORTH DAKOTA PLAN

As discussed in the Planning Landscape, we plan and operate a single Upper Midwest system that serves customers in five states. Consistent with the terms of the Settlement in Case No. PU-07-776, since 2008 we have filed our Upper Midwest Resource Plans with the North Dakota Commission, and included in each of them an analysis of a Resource Plan scenario compliant with Federal and North Dakota laws only. As with the previous 2016-2030 Upper Midwest Resource Plan, the current Plan refers to this scenario as simply the "North Dakota Plan."

[8] Selected emerging technologies are discussed further in Appendix F6.

A. Plan Components

Our Preferred Plan for our Upper Midwest system is designed to support the Company's goal of an 80 percent reduction in carbon emissions by 2030. Our 2030 goal is not driven by a particular policy directive from one of our jurisdictions. We believe planning to meet this goal is in the best interest of all our customers. Therefore, this objective is reflected in our North Dakota Plan. The North Dakota Plan differs from the Preferred Plan in the following ways:

1. All CO_2 costs have been removed;
2. Incremental Demand Response (DR) was removed; and
3. Community Solar Garden (CSG) program costs are excluded.

When we developed our Preferred Plan we included the externality and regulatory costs of CO_2 approved by the Minnesota Public Utilities Commission. Removing the CO_2 in the North Dakota Plan had only minor impacts as shown below:

Table 4-2: Expansion Plan Comparisons
Preferred Plan – North Dakota Plan – Summary of Differences

Preferred Plan

Wind	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Distributed Solar	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

In the modeling for the North Dakota Plan, solar additions for 2027-2029 in the Preferred Plan are delayed to 2029-2030. As discussed previously, our Preferred Plan also includes a large incremental addition of DR in recognition of the Minnesota Commission's Order in our last Resource Plan requiring 400 MW of additional DR by 2023. While we expect most of these DR programs to be implemented in Minnesota, as we continue to develop additional DR programs for our system we would consider proposing to add cost-effective DR programs for our North Dakota customers as well.

The exclusion of the costs of CSG does not impact the resources additions for the North Dakota Plan. Instead, the costs of CSG are allocated so that North Dakota customers pay a market rate for the energy from the CSG resources. The allocation of the costs to North Dakota will also reflect previous cost-recovery decisions that exclude costs related to the disputed resources identified in the rate case Settlement of Case No. PU-12-813 and subsequent cases.

B. Resource Planning Framework Status

On December 21, 2018 we proposed a framework that outlined essential pieces of a North Dakota Resource Plan, including a default presumption that the system would continue to be planned in an integrated fashion.[9] We discussed the proposal at an informal hearing with North Dakota Commissioners in March of this year. The North Dakota Commission confirmed that they are interested in a more formalized resource planning process. We look forward to working with the North Dakota Commission and Staff to further develop a North Dakota planning process.

C. North Dakota Combustion Turbine

Pursuant to the Settlement in Case No. PU-12-813, the Company agreed to take steps to locate a system natural gas CT in the state of North Dakota, to be operational by December 31, 2025. Specifically, Xcel Energy agreed to:

> *…develop, own, and operate (or alternatively, cause to be developed and operated on its behalf through a power purchase agreement or other contractual arrangement) a combustion turbine with a capacity of at least 200 MW in eastern North Dakota, no later than December 31, 2025. The costs of the generating facility will be allocated to all state jurisdictions served by the Company in a manner consistent with other NSP System resources. Attainment of this commitment is contingent on the Company's receipt of all necessary and appropriate permits and regulatory approvals. Further, except as modified by this Section II, all provisions of the 2036 Commitment remain in place, including without limitation, the requirements that the combustion turbine agreed to in this paragraph reasonably 1) addresses a system capacity need and 2) represents a least-cost resource when also considering the local reliability and system benefits of developing thermal generation in North Dakota.*

The five-year Action Plan associated with this 2020-2034 Resource Plan runs through

[9] *See* North Dakota Case No. PU-12-813.

2024. Thus, the Commission will not find specific mention of a North Dakota natural gas CT addition in the current short-term Action Plan; rather, proposed resource additions in 2025 will be within the Action Plan developed in the next Resource Planning cycle and addressed directly in that filing.

While the longer-term plan for resource additions do not reflect a firm peaking addition until 2031, we acknowledge the above-stated Settlement commitment and will continue to assess NSP System capacity needs over the next couple of years, the likelihood of gaining the necessary approvals in all NSP System states, and the operational feasibility and cost-effectiveness of a peaking plant located in eastern North Dakota. Given the long planning horizons, many things can change in the next 5 to 10 years in terms of energy policy, technology, and economic conditions. We remain committed to locating more generation in the state and a more timely and beneficial option may become evident over time.

V. PUBLIC INTEREST ANALYSIS

Based on our detailed analysis, we conclude that the Preferred Plan is in the public interest. We believe it best balances our goals to ensure reliability, achieve significant carbon reduction, and maintain reasonable costs to customers.

The Commission's Rules identify the factors that the Commission is to consider when determining if the Resource Plan selected is in the public interest.[10] Specifically, these Rules require that resource options and resource plans are to be evaluated on their ability to:

- Maintain or improve the adequacy and reliability of utility service,
- Keep the customers' bills and the utility rates as low as practicable, given regulatory and other constraints,
- Minimize adverse socioeconomic effects and adverse effects upon the environment,
- Enhance the utility's ability to respond to changes in the financial, social, and technological factors affecting its operations, and
- Limit the risk of adverse effects on the utility and its customers from financial, social, and technological factors that the utility cannot control.

[10] Minn. R. 7843.0500, subp. 3.

Our Preferred Plan is best able to meet these criteria, especially when analyzed on a comprehensive basis in light of the planning landscape the Company and the broader industry operate within.

A. Reliability

Our Preferred Plan is designed to allow us to continue to provide safe and reliable service to our customers as we take steps to achieve deep carbon reductions in our electricity mix. We know that as we, and other utilities in Minnesota, the Upper Midwest, and the broader MISO market retire baseload units and continue to add substantial variable renewable generation capacity to the grid, planning processes will need to adapt to ensure a reliable and stable grid. We have done the work to understand potential grid impacts from the orderly fleet transition we propose. We have also developed a Reliability Requirement that will ensure we continue to serve our customers' energy needs every hour of every day in the interim until MISO updates its planning construct to recognize the changes underway. We discuss the work we have done to we meet our obligation to provide reliable service in our Baseload Study, provided as Appendix J1.

Related, in connection with our pursuit of vast new quantities of renewables, we have included the proposed MEC acquisition and planned Sherco CC as resources in our Preferred Plan in order to ensure new renewable resources can be adequately integrated. We also leave open the possibility that future firm, dispatchable needs identified in the Plan could be met with non-emitting alternatives such as DR or energy storage. Finally, we discuss other supporting infrastructure that will support our goals to integrate additional variable renewable energy in Appendix I. By including these various elements, our Preferred Plan positions us to ensure the continued adequacy and reliability of the NSP system throughout the planning period and beyond.

B. Impact to Customer Bills

Affordability is one of the key objectives that framed our analysis. Our Preferred Plan achieves significant carbon reductions while ensuring reliability at a cost in line with expected inflation rates, or an annual cost increase of just over one percent, on average, over the planning period. The fact that we do not need to take any actions in the near-term supports the flexibility that we seek with this plan, which we believe is more beneficial now than ever – given the pace of technological innovation and cost reductions we have observed and expect to continue into the future. Therefore, we believe that our Preferred Plan will keep our rates as low as practicable, given future market and other uncertainties as we have described in this Plan.

C. Environmental Effects

Xcel Energy is leading the nation with an ambitious goal of serving our customers with a completely carbon-free resource mix by 2050 – and on our way to reaching this goal, reducing our carbon emissions by 80 percent from 2005 levels by 2030. Our Preferred Plan is a critical step in planning to meet these ambitious carbon reduction goals, while also keeping in mind the socioeconomic impacts of retiring large baseload generation units. We have proposed to close all of our remaining coal units by the end of 2030, which will significantly reduce the amount of carbon attributable to our system. At the same time, we are also planning to vastly expand the amount of renewable energy capacity on our system, and continue to operate Monticello through 2040 – both of which will provide substantial amounts of clean energy to serve our customers. All of these actions work to ensure we achieve our environmental goals and carbon-free vision.[11]

D. Socioeconomic Impacts

We recognize that plant closures can have a significant impact on our plant employees and the communities that have hosted our plants for many years – and we bore this in mind when developing our Preferred Plan. By announcing our plans to retire Sherco 3 and King far in advance of proposed retirement dates, employees will have time to build additional skills and transition to other parts of the Company, if desired. Like we have in the past, we will work with these employees to support their transitions. We will also continue working with the host communities and other stakeholders around those communities. We are currently working, in conjunction with CEE and Minnesota Power, to understand the socioeconomic effects of the plants and their closure on host communities. This commitment is evidenced in the work we have been doing in the Sherco area, after closure of our Sherco Units 1 and 2 was approved in our last Resource Plan. Among others things, we plan to develop our own gas CC plant on the Sherco site. We have been working to draw new development to the area, and with existing and prospective large industrial customers to locate facilities in the area, which will help to offset tax and other impacts from the closure of the coal units. These efforts will generate socioeconomic benefits through facility construction and ongoing operations. Our clean energy efforts also generate socioeconomic benefits, both in preserving key nuclear jobs through the Monticello

[11] Note that resources we include our Preferred Plan meets and exceeds Minnesota greenhouse gas reduction goals under 216H.02, the renewable energy standard under 216B.1691 and the solar energy standard under 216B.1691, 2f.

life extension, and spurring a large amount of new renewable construction over the planning period.

E. Flexibility to Respond to Change

Our Preferred Plan positions the Company well in the current planning landscape – meeting near-term needs and creating flexibility for the future. As we have described, planning constructs, policies, and technology costs are all creating uncertainty, which lead us to prioritize strategic flexibility in our plans to preserve the most value for our customers. For example, even though our modeling results show that extending the operating life of Prairie Island would be cost-effective under today's market conditions, we also know those conditions can change rapidly. Thus, we have deferred a decision regarding Prairie Island extension until the next Resource Plan. We also have said that we are open to meeting our firm and dispatchable capacity needs in the out-years of our Plan with options other than natural gas units, to the extent technologies sufficiently develop and are economically-favorable at that time. This flexibility enhances our ability to respond to changes in our planning landscape that would affect our operations during the planning period and preserves some agility for us to respond and adapt to these factors

F. Limiting Risks

Much like the flexibility to respond to change, the strategic flexibility inherent in our Preferred Plan limits the risk of adverse effects on the Company and our customers from factors beyond our control. For example, the Reliability Requirement we developed and incorporated into our modeling ensures that we have planned for adequate firm and dispatchable energy to meet our customers' needs until current planning constructs adapt.

Our Preferred Plan represents the best option to meet customers' needs in light of the planning landscape for the planning period, presents the best path forward for the Company, our customers, and the energy future of our Upper Midwest system, and is thus in the public interest.

VI. CONCLUSION

The Preferred Plan we propose in this 2020-2034 Upper Midwest Resource Plan reflects extensive collaboration with stakeholders as well as independent expert analysis. Our Preferred Plan proposes to eliminate coal, add even more renewables, and continue our industry-leading EE and DR programs, all while preserving reliability and affordability for our customers. It also meets the varied interests of our five-state Upper Midwest region. And by planning ahead and charting an orderly, gradual transition of our generation fleet, we believe we can achieve all of these goals while managing the impacts to our host communities and employees, preserving the reliability and stability of our system, and maintaining affordability for our customers. For these reasons, and those discussed throughout this filing, we believe our Preferred Plan is in the public interest and merits Commission approval.

CHAPTER 5
ECONOMIC MODELING FRAMEWORK

We have used the Strategist Resource Planning model to perform our economic analyses since 2000. We use Strategist as our primary resource planning software to estimate the costs of various resource expansion plan options, evaluate specific capacity alternatives, and measure the potential risks of new environmental legislation and other policy scenarios. Strategist results are a decision support tool to guide development and selection of a Preferred Plan and test the robustness of the Plan under a variety of assumptions and sensitivities.

To ultimately identify and refine our Preferred Plan, we created 15 scenarios that examined different combinations and timing of baseload unit retirements, and the resulting size, type, and timing of new resources we would need to add in order to continue meeting customers' needs and achieve our 2030 carbon reduction goals. We refer to these scenarios as "baseload study scenarios."

As we developed the various baseload study scenarios, we also conducted DR and EE Bundle analyses. This is the first Resource Plan in which DR and EE Bundles are considered supply-side resources, and as such, we had to undertake iterative analysis alongside our scenario analysis to analyze these options appropriately. Finally, after this analysis was completed, we used the outcomes and sensitivity tests to select and refine a Preferred Plan.

We discuss our assumptions, scenarios, sensitivities and how these inputs guided selection of our Preferred Plan in more detail below.

I. ASSUMPTIONS

There are several assumptions included in our baseline data inputs that are common across all scenarios studied. These factors may, in some cases, be varied within sensitivities, but are largely kept constant across the default study of each scenario.

Important starting assumptions in our analysis include:

Load Forecast. The Company employs standard probabilistic analyses to determine our load and energy demand forecasts. Our resource planning process takes the 50 percent probability level forecasts for both peak demand and energy requirements as an input, we provide a detailed description of our load forecasting methodology as Appendix F1.

In the past, these forecasts have included adjustments to account for the effects of EE as a load modifier. In order to accommodate modeling EE as a supply-side resource in this Resource Planning process, we have not included any going forward EE impacts in the load forecast for the 2020-2034 period. These energy and demand savings are now included in the three EE Bundles that we evaluate as supply-side resources.

We also incorporated an effective planning reserve margin of 2.98 percent, per MISO requirements. As discussed in Chapter 3, MISO instituted an 8.4 percent planning reserve margin requirement in the 2018-2019 planning year, and our system has a 95 percent MISO system coincident factor. Thus, our effective reserve margin is calculated in the following manner:

Figure 5-1: Effective Reserve Margin Used in Strategist Modeling

$$(95\ percent\ coincidence\ factor)\ x\ (1 + 8.4\ percent)\ -\ 1 = 2.98\ percent\ effective\ reserve\ margin$$

Existing Fleet. We develop forecasts to model our existing fleet's cost and performance assumptions (such as variable O&M, heat rate, forced outage rate, maintenance requirements, etc.) based on historical data, with adjustments for known future changes where applicable. Additional operational and performance assumptions include:

- Retirement of Sherco Units 1 and 2 in 2026 and 2023, respectively, as approved in our last Resource Plan;
- Remaining coal units are dispatched economically beginning in 2028, reflecting our expectations that MISO transitions to a multi-day commitment approach that more efficiently commits resources in accordance with load serving needs over a longer time horizon;
- Retirement of all other facilities at their current expected end of life if within the resource planning period, unless we have specifically included costs of life extension (e.g. for nuclear units in scenarios that include life extension);
- Continuation of our existing PPAs until their contractual termination dates, and
- Continued operation of the Company's owned hydroelectric resources based on historical performance.

Additional cost –related assumptions include:

- Costs are escalated based on corporate estimates of expected inflation rates,
- Costs associated with early retirement of the existing baseload coal units (King and Sherco 3), as well as costs for early retirement or re-licensing the nuclear plants were developed for use in the Baseload Study modeling.

Renewable Energy. In addition to the 1,850 MW of wind we are in the process of adding to the NSP System since our last Resource Plan, we have assumed:

- Currently approved and/or operating renewable facilities (including both those facilities we plan to own and those we plan to contract) are assumed to be replaced at their end of life or contract expiration with the equivalent amount of similar energy from generic wind and solar resources (i.e. wind would replace wind, solar would replace solar). We refer to this as "no going back;"
- Accreditation of wind resources based on the 2018-2019 Planning Year 15.6 percent MISO ELCC, accreditation of solar resources at the default 50 percent ELCC. For modeling purposes we assume these values remain the same throughout the modeling period;
- No extension of the federal production tax credit (PTC) or investment tax credit (ITC)[1] past the expiration dates as per current law.

Markets. We run scenarios in Strategist both with "markets on" (i.e. where we can buy and sell energy in the MISO wholesale market) and "markets off" (i.e. where we cannot sell to the market, but purchases are still modeled). We use the "markets on" view as a default assumption because this is more reflective of our realistic operations. Sensitivities with markets off help us test the effects of this assumption on the various scenarios.

Wholesale electricity price forecasts. Our electric power market prices are developed from fundamentally-based forecasts from external analysts Wood Mackenzie, CERA and PIRA. The forecasts we receive from these third party analysts provide monthly average on- and off-peak market pricing at the Minn Hub. We then use that market data to create an hourly shape for each month, based on the amount of thermal generation dispatched on our system. The methodology results in lower hourly locational marginal prices (LMPs) during times when a significant amount of renewable energy is on the system and higher hourly LMPs when amounts of available renewable energy are lower. Shaping the hourly prices in this manner provides a more conservative view of potential benefits we may realize from selling excess generation to the market.

[1] The ITC reverts to 10% in 2022 and beyond, per current law.

Purchase and sales limits. In our Strategist model, we include a limit as to the amount of energy that we are able to either purchase from or sell into the MISO market. This limit was developed using results from the 2018 MISO Transmission Expansion Plan (MTEP) model results and evaluating maximum levels of market interaction achieved in that modeling. For 2020-2023 we assume a market interaction limit of 1,800 MW which grows to 2,300 MW after 2023, based on the anticipated in service of the Cardinal to Hickory Creek transmission line which is expected to increase transmission outlet in our region.

Emissions rates and costs. Emission rates for existing and planned resources are consistent with historical and expected performance. We assume the following costs[2] and apply them to emitting resources as relevant:

- Achievement of an 80 percent reduction in CO_2 serving retail customers, as measured from 2005 levels, by 2030. The overall carbon emissions are allowed to increase slightly from these levels at the retirement dates of the nuclear fleet, which vary by scenario;
- $ 25.00 per ton CO_2 as a regulatory cost, starting in 2025 and escalating at inflation, with the high CO_2 externality value used prior to 2025. The societal value of CO_2 as an externality and other combinations of externality and regulatory costs were included as sensitivity cases;
- The Minnesota Commission's high externality values for other specified emissions.

Generic Resources. Strategist uses generically-defined resources to meet future demand when our already existing and approved resources are not sufficient in a given year. Generic resources are modeled as incremental units of a certain installed capacity size, but these sizes are chosen based on the amount of UCAP, or the MISO accredited capacity value the units would yield. For example, although the generic unit size for solar is rather large (500 MW installed capacity), the resource adequacy or MISO capacity credit value we would expect to receive for a plant of that size is half that (250 MW), which is more comparable to a generic thermal or storage plant we may assess. Similarly, wind UCAP values are discounted to 15.6 percent of ICAP.

[2] Note: As further discussed below, these costs are not used in evaluating the cost of our Preferred Plan for North Dakota. See our discussion regarding the North Dakota Plan in Chapter 4: Preferred Plan.

Generic units ICAP values included in modeling are as follows:[3]

- 331 MW gas-fired combustion turbine peaking unit (CT),
- 206 MW gas-fired combustion turbine peaking unit (CT),
- 856 MW gas-fired combined cycle intermediate unit (CC),
- 331 MW energy storage project, with costs and performance comparable to lithium-ion battery technology,
- 750 MW wind project
- 500 MW grid-scale single-axis tracking solar project
- 100 MW distributed solar project

Appendix F2: Strategist Modeling Assumptions & Inputs, provides more detail on Strategist assumptions. Please see Appendix F6: Resource Options, for additional discussion on supply-side resource options included in the analysis.

Customer Programs. Incremental customer programs for DR and EE were included as potential resources in the Strategist model. The derivation of these three DR and three EE "Bundles" are described in Appendix F6.

It is important to note that these Bundles represent generic DSM additions and therefore may not perfectly align with the size and timing of actual DR or EE additions to the system in the future. These Bundles were developed immediately after receiving third party studies for incorporation into modeling, without the benefit of time to develop detailed implementation plans to achieve the levels of DSM in each Bundle. Therefore, for incremental DR resource additions in particular, while the size and timing of the first Bundle generally achieves the ordered 400 MW by 2023, the actual implementation plans which detail the specific size, type, and timing of incremental additions will likely differ. Procurement plans are illustrated in Appendix G1: Demand Side Management.

DER is modeled with base and high adoptions assumptions, using similar levels as provided in our 2018 IDP filing. We discuss our DER forecasts in Appendix F1: Load and Distributed Energy Resource Forecasting.

[3] The cost and performance data for these units are based on consultant's estimates, publicly available third-party data, and internal company data. Availability dates are selected based on our estimates of the lead time needed for regulatory approvals, financing, permitting and construction.

II. SCENARIOS

As noted above, we created 15 scenarios to examine combinations and timing of baseload unit retirements, and the resulting size, type, and timing of new resources we would need to add in order to continue meeting customers' needs and achieve our 2030 carbon reduction goals. We describe key parameters of these scenarios below.

A. Reference Case Scenario

We describe the development of our Reference Case in Chapter 3: Minimum System Needs. The Reference Case (Scenario 1) is an extension of our 2015 Resource Plan, in that all of the baseload units retire at their currently scheduled retirement dates, and serves as our starting point. The approved 1,850 MW wind portfolio that is in progress is included, along with generic wind and solar units added to the plan to ensure that we do not fall below the current level of renewables we have on our system (i.e. a "no going back" portfolio). Additional renewable units are evaluated and optimized in the modeling and added where economic. In the original phases of the modeling, the DR and EE Bundles were evaluated as optimized economic alternatives, as were distributed solar, storage, and thermal CT and CC resources. The Sherco CC unit and owned MEC CC unit were included in the Expansion Plan. Firm peaking resources were included in the plan as needed to maintain the Reliability Requirement criteria.

To determine the optimal strategy regarding the future of the baseload fleet, we developed additional scenarios with varying combinations of baseload resource retirement dates. The resulting system needs were then met with a Strategist model-optimized portfolio of new resources. Internal finance, energy supply, and nuclear subject matte experts worked to develop a robust set of assumptions and potential retirement dates for the baseload units. These input assumptions include: ongoing capital expenditures, O&M expenses and decommissioning and/or life extension costs. We also incorporated the planning level estimates from the MISO Y2 studies performed as part of our Baseload Study that informed our Preferred Plan. See Appendix J1 for more details regarding this study. The scenarios we evaluated can be generally grouped into families, as described below.

B. Early Coal Family

This family of scenarios is designed to evaluate the economics (i.e. revenue requirement impacts) of retiring King and/or Sherco 3 early. We did not study life extension for coal facilities. For the early coal retirement scenarios, the early retirement date for King was assumed to be the end of 2028, and for Sherco 3 the

early date was the end of 2030. We chose these retirement dates because they generally allow an orderly and staged transition, with a major coal retirement every two to three years. In the all early coal scenarios, for example, the retirement schedule is Sherco 2 in 2023, Sherco 1 in 2026, King in 2028 and Sherco 3 in 2030.

- Scenario 2 **(Early King)** – King is retired at the end of 2028. Sherco 3 and the nuclear units are unchanged.
- Scenario 3 **(Early Sherco 3**) – Sherco 3 is retired at the end of 2030. King and the nuclear units are unchanged.
- Scenario 4 **(Early All Coal)** – King is retired at the end of 2028, Sherco 3 is retired at the end of 2030, and the nuclear units are unchanged.

C. Early Nuclear Family

This family of scenarios is designed to test the economics of retiring Monticello and/or Prairie Island early, either alone or together, and with the combination of early coal retirements. For the early nuclear retirement scenarios, the early retirement date for Monticello was assumed to be the end of 2026 and for Prairie Island 1 and 2 it was the end of 2024 and 2025, respectively. We chose these retirement dates as we felt they best balanced the need for adequate lead time to enable an early major nuclear retirement with the desire to evaluate retirement scenarios that occur well ahead of the existing retirement dates in the 2030s.

- Scenario 5 **(Early Monticello)** – Monticello is retired at the end of 2026. Coal and Prairie Island is unchanged.
- Scenario 6 **(Early Prairie Island)** – Prairie Island is fully retired by the end of 2025. Coal and Monticello is unchanged.
- Scenario 7 **(Early All Nuclear)** – Prairie Island and Monticello are both retired early per the years above, the coal units are unchanged.
- Scenario 8 **(Early All Baseload)** – All baseload units, including coal and nuclear, are retired early per the years indicated above.

D. Extend Nuclear Family

This family of scenarios is designed to test the economics of re-licensing Monticello and/or Prairie Island and extending operational life by 10 years over the current retirement dates. For the extend nuclear scenarios, the revised date for Monticello was assumed to be the end of 2040 and for Prairie Island 1 and 2 was the end of 2043 and 2044, respectively.

- Scenario 9 (**Early Coal, Extend Monticello)** – All coal was retired at the early dates and Monticello is extended for 10 years. Prairie Island is unchanged.
- Scenario 10 (**Early King, Extend Monticello)** – King was retired at the early date and Monticello is extended for 10 years. Sherco 3 and Prairie Island are unchanged.
- Scenario 11**(Early Coal, Extend Prairie Island)** – All coal was retired at the early dates and Prairie Island is extended for 10 years. Monticello is unchanged.
- Scenario 12 **(Early Coal, Extend All Nuclear)** – All coal was retired at the early dates and both Monticello and Prairie Island are extended for 10 years.
- Scenario 13 (**Extend Monticello)** –Monticello is extended for 10 years. King, Sherco 3 and Prairie Island are unchanged.
- Scenario 14 **(Extend Prairie Island)** – Prairie Island is extended for 10 years. King, Sherco 3 and Monticello are unchanged.
- Scenario 15 **(Extend All Nuclear)** –Both Monticello and Prairie Island are extended for 10 years. King and Sherco 3 are unchanged.

III. FUTURES SCENARIOS AND SENSITIVITIES

To determine how changes in our assumptions impact the costs or characteristics of different plans, we have historically evaluated how the plan responds to changes in individual input assumptions. This testing helps us assess the "robustness" of each scenario in the face of future uncertainty, meaning that we want to test how resilient the scenario is to changes in one or more key assumptions. Generally, if a given plan is extremely sensitive to changes in assumptions, it would not represent a prudent course of action for the Company to pursue, because it would subject our customers to excessive risk. While we believe there is value in evaluating the individual sensitivities, and have provided a comprehensive analysis of those sensitivities in Appendix F3, we took a slightly different approach to stress test our results in this particular Resource Plan.

A. Futures Scenarios

Consistent with the MISO MTEP Process, we adopted a scenario-based planning approach to our sensitivity analysis that we have incorporated for the first time in this Resource Plan. Since many of the input assumption variables in our modeling are correlated, we believe there is more value in looking at a combination of variable

sensitivities as opposed to "one-off" sensitivity runs. Evaluating one sensitivity at a time may isolate the impacts of the variable in question, but may not necessarily reflect a realistic future scenario.

We developed four Futures Scenarios, using the 2018 MTEP Futures as guideposts. The first two Futures Scenarios (Base PVSC and Base PVRR) represent our base assumptions, with and without carbon costs, as we have consistently provided this view as part of previous Resource Plans and are required to provide the PVRR view for our North Dakota stakeholders. The High Electrification and High Distributed Solar cases represent our new approach, in which we adjusted multiple sensitivities in each Futures Scenario to assess the combined effect of these changes. While there are certainly many assumptions we could have adjusted, we focused on the four most important variables which include fuel price forecasts, load forecasts (or variables impacting the load forecast like distributed solar), carbon and externality costs, and new resource capital costs. The assumptions made for each Futures Scenario can be seen in Table 5-1 below:

Table 5-1: 2019 Resource Plan Futures Scenarios

Futures Scenario	Description	Gas, Power, Coal Prices	Load Forecast	Carbon & Externality Costs	New Resource Capital Costs
Base Scenario (PVSC)	Base Case with Carbon Costs, Similar to MISO MTEP Continued Fleet Change (CFC) Scenario	Base	Base 50/50	High/High	Base
No Carbon (PVRR)	No Carbon Costs	Base	Base 50/50	**None**	Base
High Electrification & Low Tech Costs (PVSC)	Similar to MISO MTEP Accelerated Fleet Change (AFC) Scenario	**High**	**High Electrification Forecast**	High/High	**Low**
High Distributed Solar Deployment, Low Tech Costs (PVSC)	Similar to MISO MTEP Limited Fleet Change (LFC) Scenario	**Low**	**High DG Solar Forecast & Higher EE Levels**	High/High	**Low**

Note: bolded and underlined parameters indicate assumptions that have been modified from the Base Scenario

For the High Electrification Scenario, we examine a case in which higher load levels are expected to stimulate higher fuel demand and consequently higher overall fuel prices. To construct this Scenario, we used a high electrification forecast provided by E3, informed by their Minnesota PATHWAYS study provided as Appendix P3 to this Resource Plan, to assess the impacts of high load, high fuel price, and a low technology cost environment.

Conversely, for the High Distributed Solar Deployment Scenario, lower load levels driven by higher levels of offsetting distributed solar could reasonably be expected to drive down fuel demand and result in lower overall fuel prices. To construct this Scenario, we used an internally developed high customer adoption based distributed solar forecast to assess the impacts of low load, low fuel price and low technology cost environment. We also forced in all three EE Bundles to further reduce the load forecast and evaluate a future that truly stresses our baseload decision options.

In both the High Electrification and the High Distributed Solar Scenarios, we assumed low new resource capital costs. We believe this is an appropriate assumption to test, because trends have indicated that the market has previously underestimated realized cost reductions in renewables and other new technologies, and we feel this could continue to occur going forward. Likewise, in both these Futures Scenarios, we included carbon and externality costs, consistent with resource planning principles in Minnesota.

Figure 5-2: Peak Demand, Net of EE Impacts, by Futures Scenario (MW)

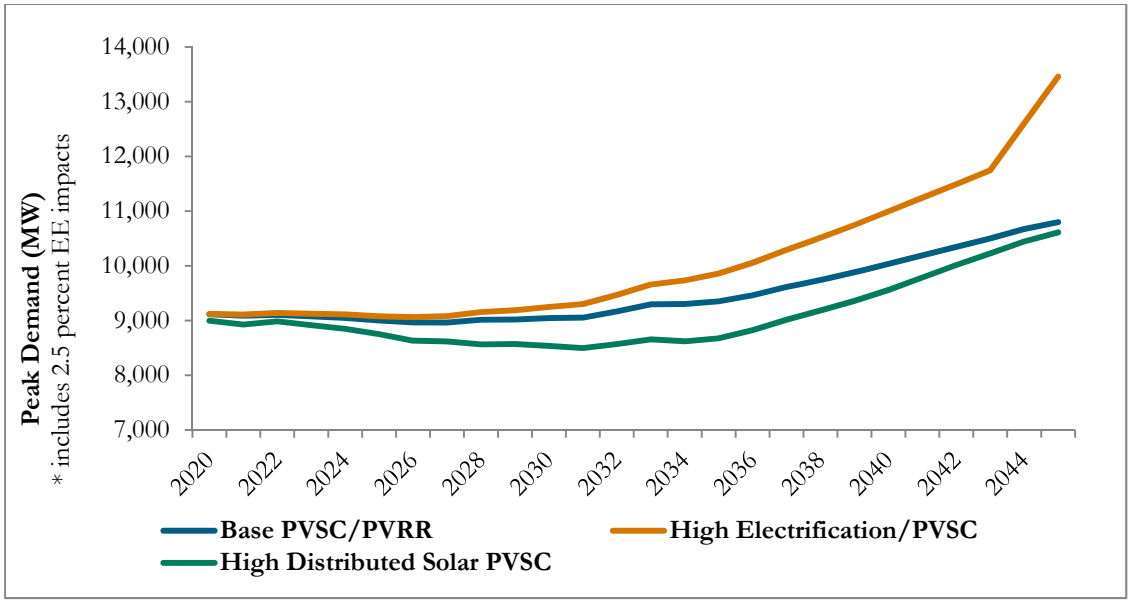

Figure 5-3: Fuel Price Assumptions, by Futures Scenario

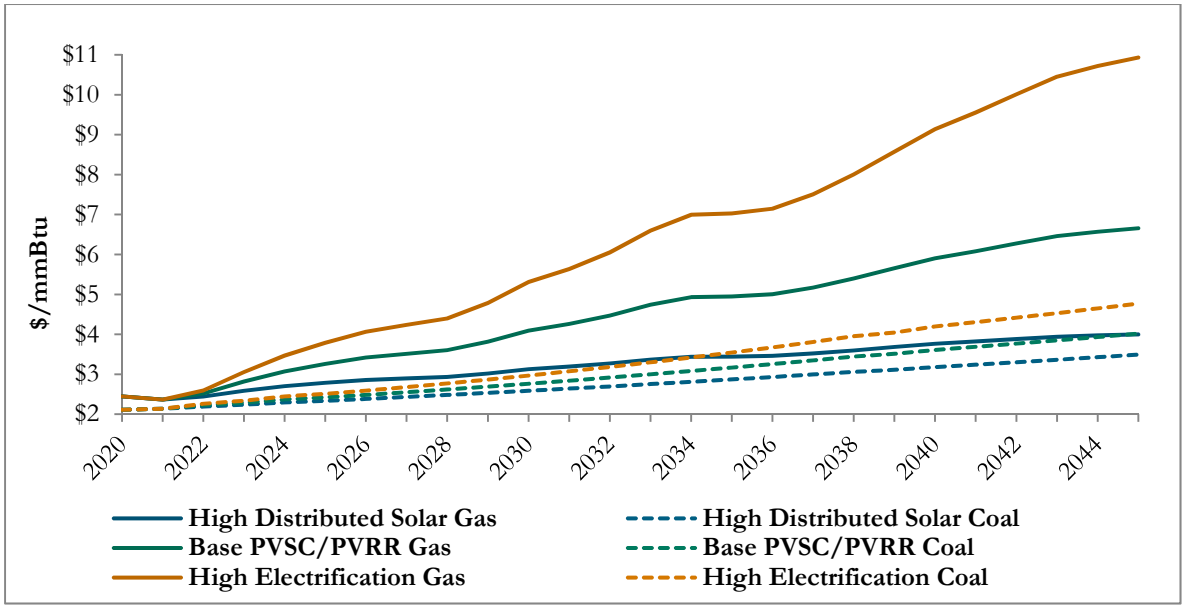

Figure 5-4: New Resource Cost Assumptions, by Futures Scenario ($/MWh; $/kW-mo)

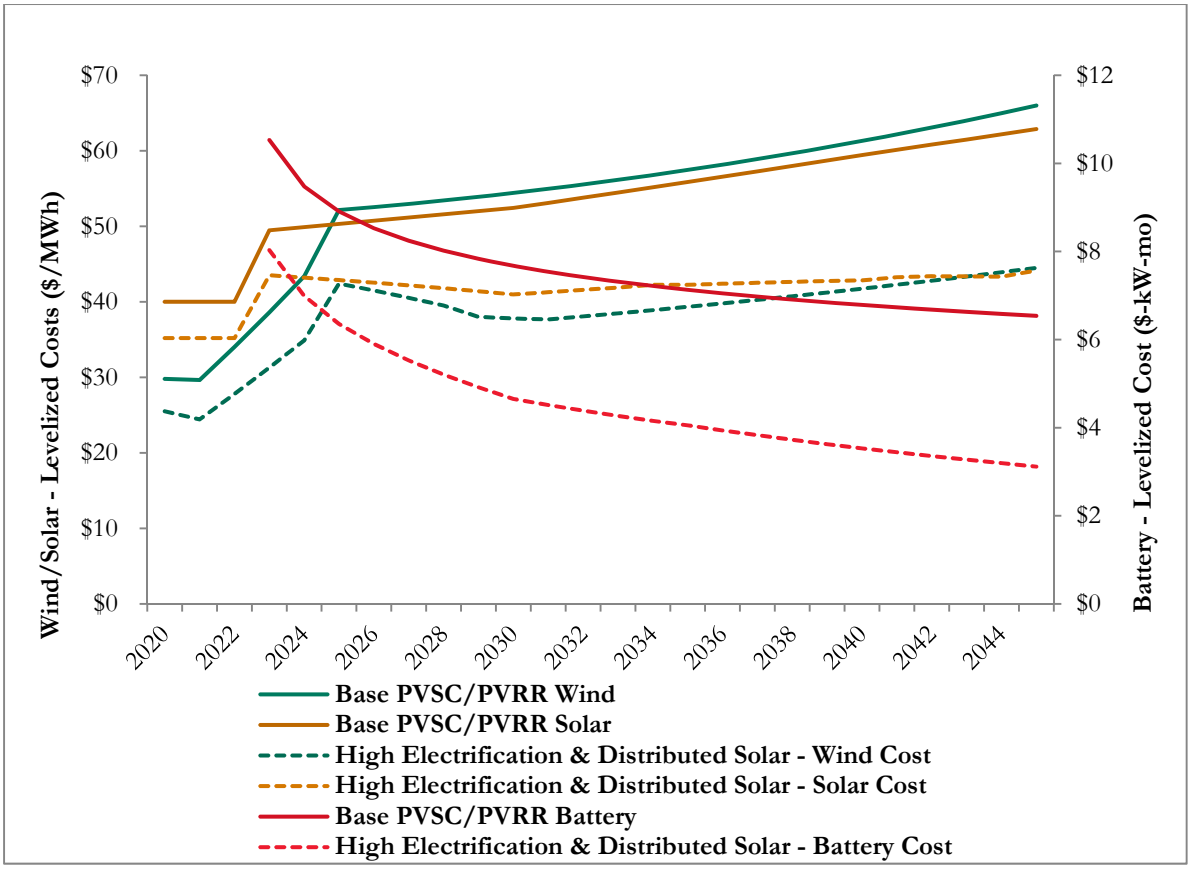

Figure 5-5: Carbon Emissions Cost Assumptions ($/Short Ton)

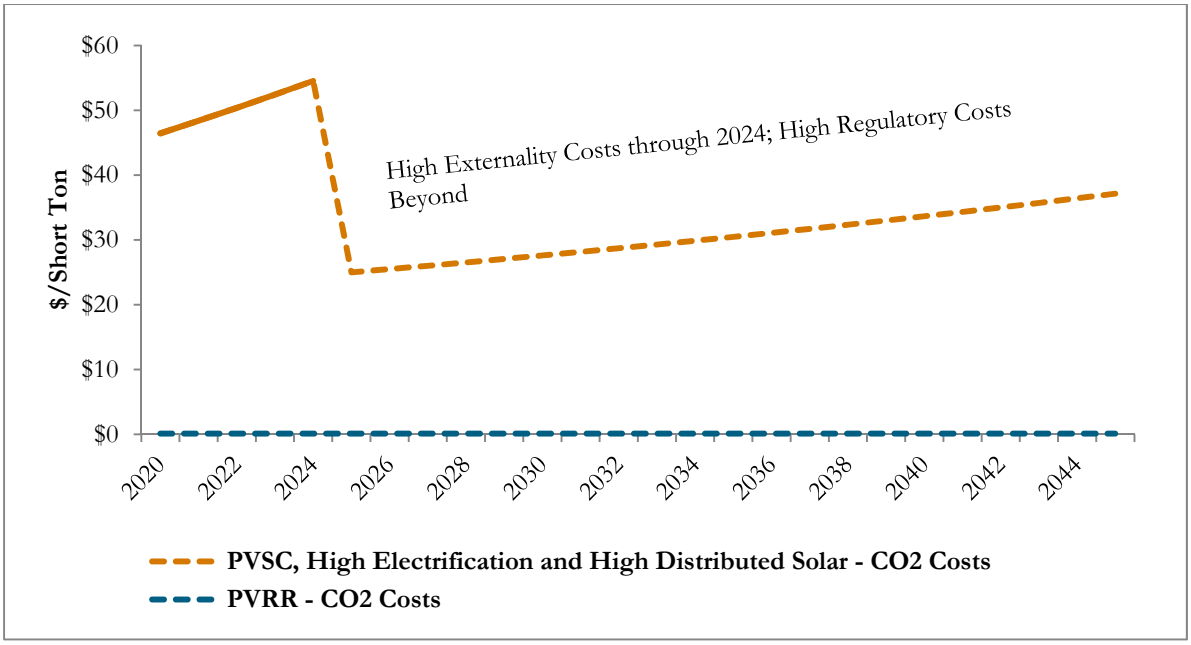


It is important to note that these Futures Scenarios were designed to test the performance of our baseload retirement decisions under plausible future states. These Futures Scenarios are not, however, intended to test which future is overall least cost for our system. We do not have full control over the level of distributed solar or electrification growth on our system, and have no control over variables such as fuel prices and new resource capital costs. As demonstrated in the next section, the Futures Scenario analysis shows that our Preferred Plan baseload decisions to retire all coal by 2030 and extend Monticello are likely to yield customer benefits relative to the Reference Case, even in a future where multiple key assumptions change simultaneously.

B. Traditional Sensitivities

While our primary focus has shifted to Futures Scenarios as opposed to the traditional single sensitivities, we still believe the individual sensitivities provide insights on potential plan performance. Therefore, consistent with previous Resource Plans, we tested the following individual sensitivities. Detailed results for these sensitivities can be found in Appendix F3.

- *Load.* The low load sensitivity includes high customer adoption-based DER growth and higher EE savings (i.e. it includes all three EE Bundles), which reduces load. The high load sensitivity includes high electrification load.

- *Fuel Price/Market Costs.* High and low price sensitivities were performed by adjusting the growth rate up and down, respectively, by 50 percent from the base forecast starting in year 2022.
- *CO_2 Values.* To examine the effect of CO_2 pricing, we tested high and low cost sensitivities. We also performed a sensitivity evaluating no CO_2 cost. The PVSC Base Case CO_2 values are based on the high externality cost values for CO_2 as determined by the Minnesota Commission through 2024.[4] The PVSC Base Case values starting in 2025 are based on the "high" end of the range of regulated costs.[5] Below is the list of carbon sensitivities.
    - Low Externality
    - Low Externality, Low Regulatory
    - Mid Externality, Mid Regulatory
    - High Externality
    - PVRR, or No Externality or Regulatory
- *Externalities.* Criteria pollutants values are derived from the high and low values for each of the three geographic locations in the Minnesota Commission Order,[6] with existing plants assigned the appropriate area and generic units assigned to "rural." The midpoint externality costs are the average of the low and high values. The high, low and midpoint externality costs are used in conjunction with the CO_2 sensitivities described above.
- *Resource Costs.* For wind, solar and battery energy storage we use NREL's *Annual Technology Baseline* (ATB) 2018 report to provide high and low technology cost sensitivity inputs. For wind and solar, we use the costs projected by the ATB directly. For batteries, we take a slightly different approach. Low and high battery costs are based the percent difference in the NREL ATB base, low and high battery cost forecasts, with this percent difference applied to the Company's base battery cost forecast. We did not adjust capital costs for thermal resources such as the generic CC or CTs, so all scenarios include our base cost assumptions for those resources.
- *Markets Sales Off.* As previously discussed, we assume that markets are "on" for each scenario. The "markets off" sensitivity represents a view in which we

[4] Minnesota Commission Order Updating Environmental Cost Values in Docket No. E999/CI-14-643 issued January 3, 2018.) at 31.
[5] Minnesota Commission Order Establishing 2018 and 2019 Estimate of Future Carbon Dioxide Regulation Costs in Docket Nos. E999/CI-07-1199 and E999/DI-17-53 issued June 11, 2018) at 12.
[6] Minnesota Commission Order Updating Environmental Cost Values in Docket No. E999/CI-14-643 issued January 3, 2018.

cannot access the market to sell energy outside our system.

IV. STRATEGIST ANALYSIS AND RESULTS

After identifying the scenarios and sensitivities for analysis, we used Strategist to identify the expansion plans for each of the 15 primary scenarios, and their resulting cost and emissions impacts. We faced a number of challenges as we tested the full capabilities of the model and attempted to be responsive to stakeholder requests to include a robust set of supply-side and demand-side resource options for consideration. As described below, we undertook an extensive process which attempted to balance the inclusion of a comprehensive set of resource options with the model's limitations, to arrive at a plan that demonstrates a high level of diligence and investigation. This analysis was performed iteratively in several rounds, as we refined the process and results, with each round informing modeling parameters for subsequent rounds. Achieving an appropriate balance between resource options and modeling runtime efficiency required the following adjustments, which are described in more detail in the sections below:

- Removal of our generic distributed solar resource options, with the understanding that if future DG solar growth exceeds our embedded assumptions, it can simply displace utility scale solar additions identified in the Preferred Plan.
- Shortening the modeling period to end in 2025, from the original 2057 end date.
- Testing EE and DR selection via optimizations, evaluating different combinations of the three EE and three DR Bundles for cost effectiveness, and then locking the optimal mix of Bundles in final optimizations.
- Manually inserting CT additions as a proxy placeholder for the firm, dispatchable resource needs driven by the Reliability Requirement. In reality, because these additions happen in the post-2030 timeframe, we expect the need will be met by a combination of firm dispatchable resource options. These may include battery storage, pumped hydro, DR, natural gas, and/or others.

A. Initial Full Optimization

In the first initial round of modeling, all technology alternatives (wind, solar, distributed solar, storage, DR, EE, CC, CT) were made available to the model and we developed a fully optimized expansion plan for each scenario through the end of the available years in Strategist (2057). We found that this stretched the capabilities of the Strategist tool. Due to the large number of alternatives, these runs took a significant

amount of time to complete; on average, five days of processing time per scenario. Further, the results were significantly truncated.[7] In these initial plans, no DR, EE, or distributed solar alternatives were selected for any of the scenarios. Although this set of initial runs was not reliable enough for drawing final conclusions, due to the truncation issues, we identified several refinements for the next round of modeling.

First, when comparing utility-scale solar and distributed solar, the model did not select any distributed solar. We reviewed the modeling data for these two alternatives and it was clear that, because both utility-scale and distributed solar have identical capacity accreditation[8] values and similar capacity factors, the model would only ever select the lower cost utility-scale solar. For modeling purposes, therefore, we removed distributed solar from the optimization in order to improve model runtime and reduce the number of truncated results. We note that this does not imply distributed solar is not a resource we anticipate will be added to our system – only that from a modeling perspective, distributed solar will not appear as cost-effective relative to utility-scale solar in the modeling process, and retaining both types of resources in the model for future runs would reduce the quality and runtime of the modeling process. As we have explained, any growth in distributed solar we experience on our system beyond what is in our embedded forecasts will simply serve to displace some of the utility-scale additions identified in our Preferred Plan.

Truncation challenges also informed the duration through which we modeled our plans. While our initial runs experienced truncation issues fairly early (beginning in the late 2020's), the further out we attempted to optimize portfolios, the more truncation occurred and the slower the simulation became. Based on this observation, we determined it was prudent to shorten the modeling period, using 2045 as the end year rather than 2057. We believed that this, in combination with adding 10 years of "end effects" in the modeling, would inform plans through the planning period (2020-2034) that were more robust and valid than the longer simulation would provide. Additionally, the availability, cost and performance assumptions for technologies become increasingly subjective far into the future, and we would not adequately account for new technologies that may develop within that timeframe.[9] Thus the results of modeling in that extended period would not be particularly robust and would likely misstate the resource mix and cost required to

[7] Truncation occurs when the Strategist model has more viable plans for a given year than the internal memory is able to store. The total collection of plans is sorted by accumulated cost up to that year, and the highest cost plans are discarded and not analyzed further. The Company's model is set to a maximum of 2,500 saved plans per year.
[8] I.e. Effective Load Carrying Capability, or ELCC.
[9] We note that an independent analysis from consultant E3 highlighted similar concerns and also conducts expansion plan modeling to 2045.

meet the Company's longer term vision of 100 percent carbon-free energy by 2050.

Further, including the DR and EE Bundles in full model optimizations proved to be a significant challenge for the Strategist model runtime efficiency. Given that the initial full optimizations resulted in no DSM being selected, we decided to pursue an alternative modeling path. For the next round of modeling, the first DR and the first EE Bundle were forced into the plans to test if "seeding" the model with these Bundles would lead to the second or third Bundles being chosen within the economic optimization.

B. Revised Targeted Optimization

The model revisions discussed above resulted in a somewhat improved modeling process, shortening runtimes and reducing truncation. However, the second round of modeling still took over two days per simulation, and displayed significant truncation, such that we determined additional refinements were needed. This process did, however, help us derive more information from our model runs that informed the final stages of the modeling process.

First, in almost all 15 scenarios, once the first DR and EE Bundles were forced in, the second EE Bundle was selected economically. No additional DR was selected. This result indicated that there was indeed a modeling bias (most likely due to truncation) that prevented selection of DR and EE, as defined by the Bundles, in the fully optimized results. We concluded that some other method of "manual" testing would be necessary to determine these resources' true cost-effectiveness.

Additionally, some of the scenario outcomes in this revised modeling process relied almost entirely on non-dispatchable or use-limited resources (wind, solar, storage) for the full capacity expansion plan. At this point, resource planning consulted with operations and engineering, and worked together to develop and implement a modeling element that would ensure the portfolio resulting from each scenario retained sufficient firm dispatchable generation to reliably serve customer capacity and energy requirements. We describe the Reliability Requirement in Appendix J2.

To incorporate the Reliability Requirement into the modeling, we added firm dispatchable load supporting resources, represented currently with CT resources as a proxy, to the expansion plan in specific years[10] to ensure the portfolio maintained the minimum level of firm dispatchable, load supporting resources as defined by the Reliability Requirement. Given the manual addition of firm dispatchable resources,

[10] Applicable years vary by scenario.

we also reduced the number of new resource alternatives available in certain years to further improve model run times. We believe this did not sacrifice or reduce the model's ability to find optimal solutions for the expansion plan. As an example, the large CC unit option was removed as an alternative in years where the incremental capacity need relative to the previous year was small. This targeted "pruning" of alternatives yielded faster run times and less truncation.

Accounting for all the aforementioned factors, we repeated scenario modeling while including: (1) the Reliability Requirement, (2) the targeted resource "pruning" and (3) one DR and one EE Bundle forced in, while still allowing the incremental DSM Bundles to be selected in the optimization. The second EE Bundle was almost always selected, while no additional DR was selected. Additionally, early coal retirement and nuclear extension scenarios emerged as potential preferred options, as they showed favorable PVSC and PVRR, when compared to other scenarios.

C. Energy Efficiency and Demand Response Analysis

In the next phase of modeling, we worked to refine the DR and EE analysis to identify the most cost effective Bundle combinations. After reviewing initial modeling results, we were confident that two Bundles of EE would likely be selected across all scenarios but wanted to conduct an additional round of tests to confirm. Given we observed strong PVSC and PVRR performance of early coal retirement and extended nuclear scenarios in previous rounds of modeling, we initially conducted DR and EE testing using Scenario 9 (Early King and Sherco 3 retirement with Monticello Extension) and Scenario 10 (Early King retirement with Monticello Extension) as a test. To adequately analyze the Bundles, we developed PVSC and PVRR matrices by selecting a scenario and performing optimizations that included each permutation of the three DR and three EE Bundles. This manual process eliminated the potential for DR and EE truncation, thus allowing us to conduct a robust analysis of each option.

We show results for Scenario 9 as an example below, and note that in both cases the 0 DR/2 EE combination returns the lowest PVSC and PVRR results.

Table 5-2: Scenario 9 (Preferred Plan) DR and EE Cost Effectiveness Analyses ($2019 millions)

PVSC				
	0 DR	**1 DR**	**2 DR**	**3 DR**
0 EE	$48,486	$48,203	$48,502	$48,745
1 EE	$45,390	$45,670	$45,947	$46,152
2 EE	$45,173	$45,512	$45,726	$45,910
3 EE	$45,847	$46,166	$46,389	$46,596

PVSC Deltas (as compared to 0 DR/2 EE)				
	0 DR	**1 DR**	**2 DR**	**3 DR**
0 EE	$3,313	$3,030	$3,329	$3,572
1 EE	$217	$497	$774	$979
2 EE	-	$339	$553	$737
3 EE	$674	$993	$1,217	$1,423

PVRR				
	0 DR	**1 DR**	**2 DR**	**3 DR**
0 EE	$40,029	$40,216	$40,478	$40,653
1 EE	$37,657	$37,910	$38,182	$38,344
2 EE	$37,476	$37,784	$37,925	$38,143
3 EE	$38,374	$38,589	$38,802	$39,009

PVRR Deltas (as compared to 0 DR/2 EE)				
	0 DR	**1 DR**	**2 DR**	**3 DR**
0 EE	$2,554	$2,741	$3,003	$3,177
1 EE	$181	$435	$706	$869
2 EE	-	$308	$450	$668
3 EE	$899	$1,113	$1,327	$1,533

Based on this result, subsequent model runs for the baseload analysis locked in 0 DR Bundles and two EE Bundles, and removed consideration of the remaining DR and EE Bundles from the optimization process. As discussed further in Section V and elsewhere in this Resource Plan however, we ultimately included the first Bundle of DR as part of the Expansion Plan.

D. Final Scenario Analysis

The last round of baseload scenario modeling incorporated the results of the previous rounds into defining and executing a final analysis, which we used to draw conclusions on the relative economics and operational performance of the 15 baseload scenarios. For the final model runs, two EE Bundles were manually added to the plans, and the remaining Bundles were removed from the optimization, per our previous findings that they would not be selected. The Reliability Requirement was included as a constraint, and the number and timing of alternatives were reduced as previously described, in order to improve model run performance without sacrificing the ability to effectively optimize remaining resource options. We then created expansion plans for all 15 scenarios, using PVSC assumptions, and completed the full set of sensitivities.[11]

[11] Minn. Stat. § 216B.2423

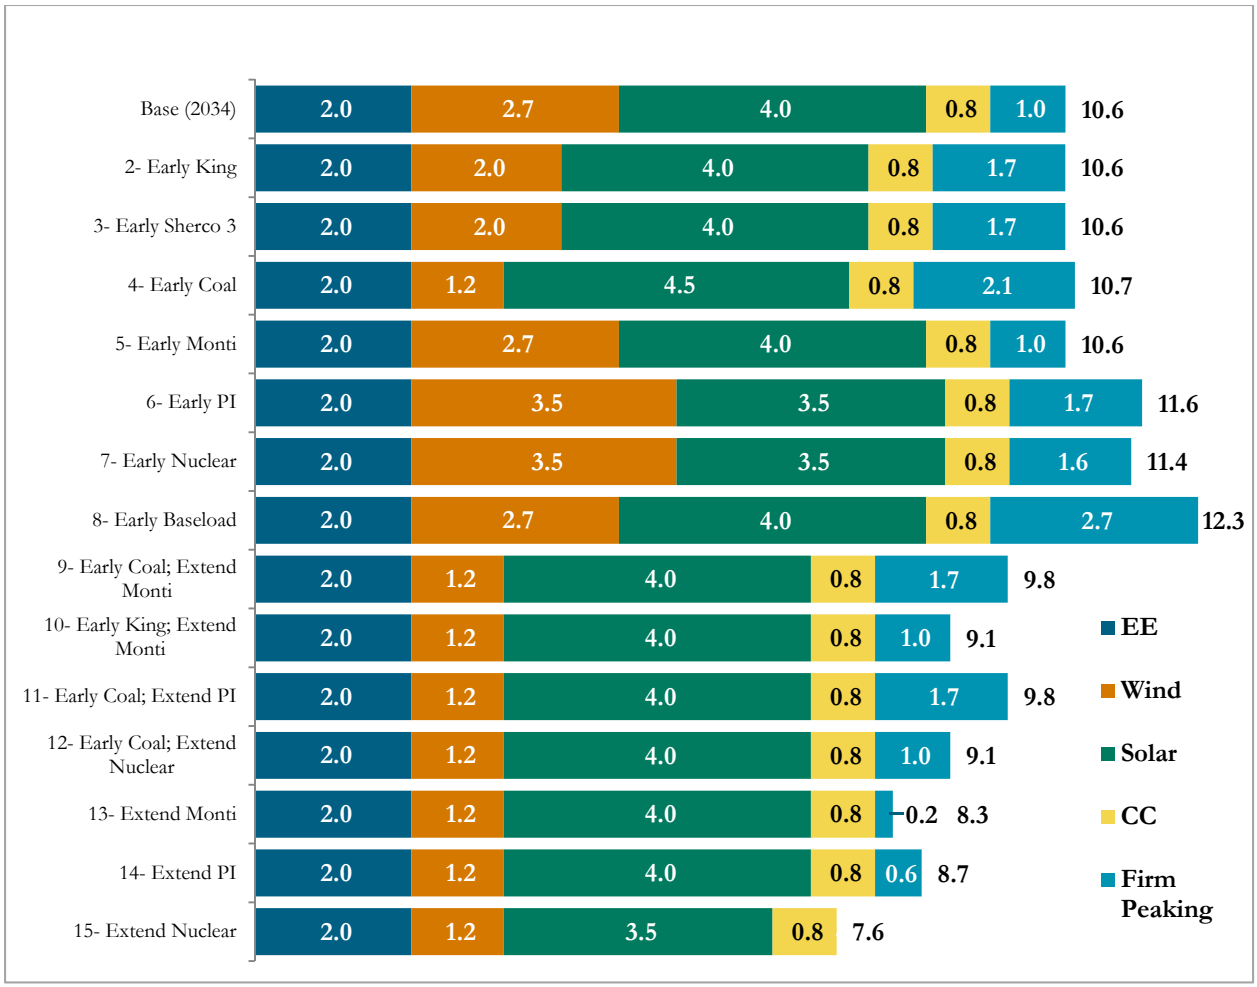
E. Modeling Results and Conclusions

Completing baseload scenario runs, as described above, allows us to examine Scenario outcomes side-by-side, to evaluate their benefits and drawbacks. Among other factors, we examine each Scenario's resource expansion profile and carbon emissions outcomes, present value costs, and several indicators of risk.

1. Capacity Additions and Emissions Reductions

The cumulative expansion plan additions through the planning period for the 15 scenarios are shown below in Figure 5-6.

Figure 5-6: Expansion Plans by Scenario
(GW, Cumulative Nameplate Capacity Resource Additions by Fuel Type)



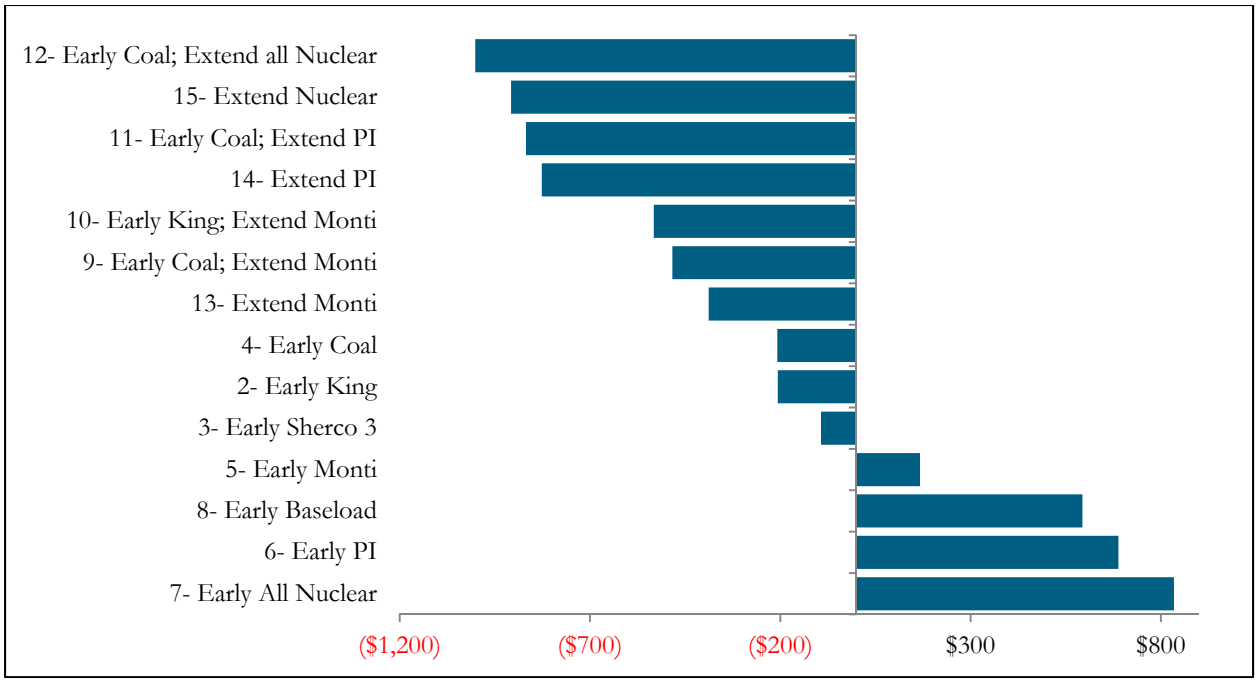
As the 80 percent carbon emissions reduction target was included as a modeling

parameter, all the scenarios achieve this goal and remain under the emissions threshold from 2030 throughout the planning period. There is minimal variability between Scenarios on this measure, other than the timeframe in which they first reach 80 percent reduction levels.

2. *Present Value Costs*

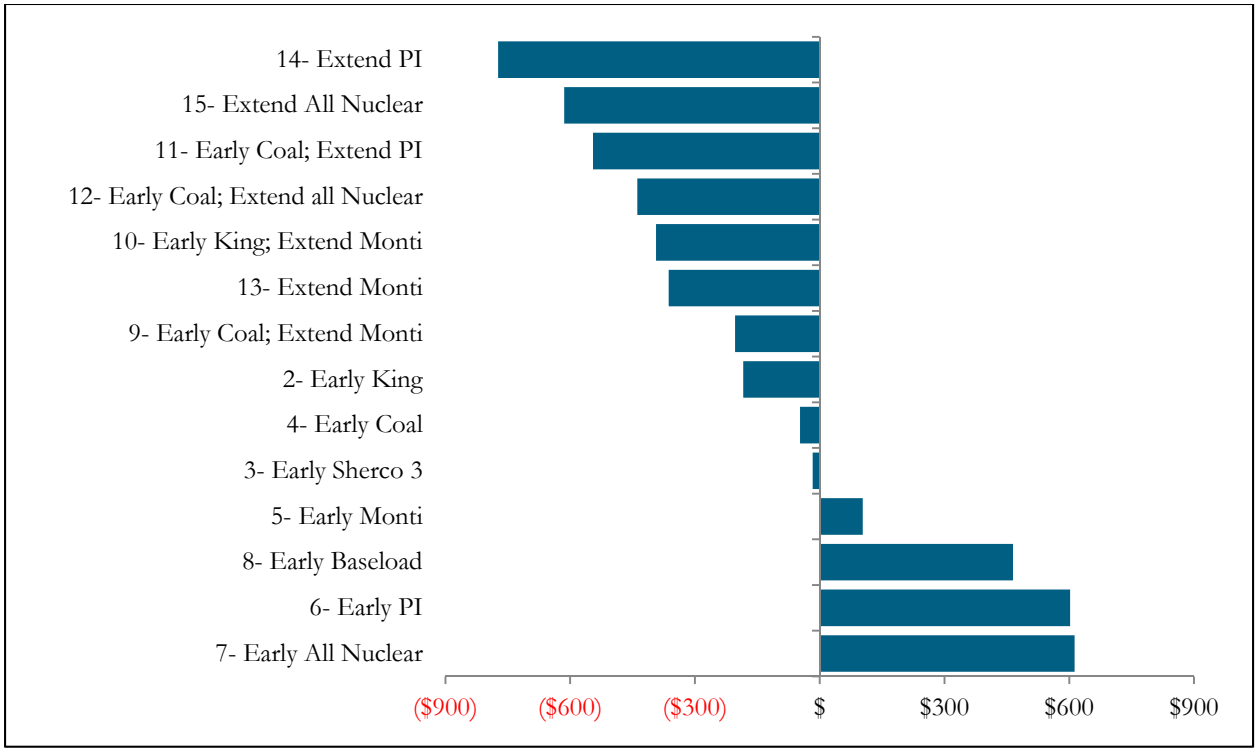
In general, plans that favored early coal retirements and nuclear extensions were the lowest cost plans, both in terms of PVSC and PVRR. The results for the 15 scenarios from the final modeling runs are shown below in Figures 5-7 and 5-8. The figures show the net present value (NPV) delta of modeled costs compared to Scenario 1 (the Reference Scenario), with negative values representing customer savings relative to the Reference Scenario and positive values representing increased costs.[12]

Figure 5-7: Scenario PVSC Deltas from Reference Case ($2019 millions)



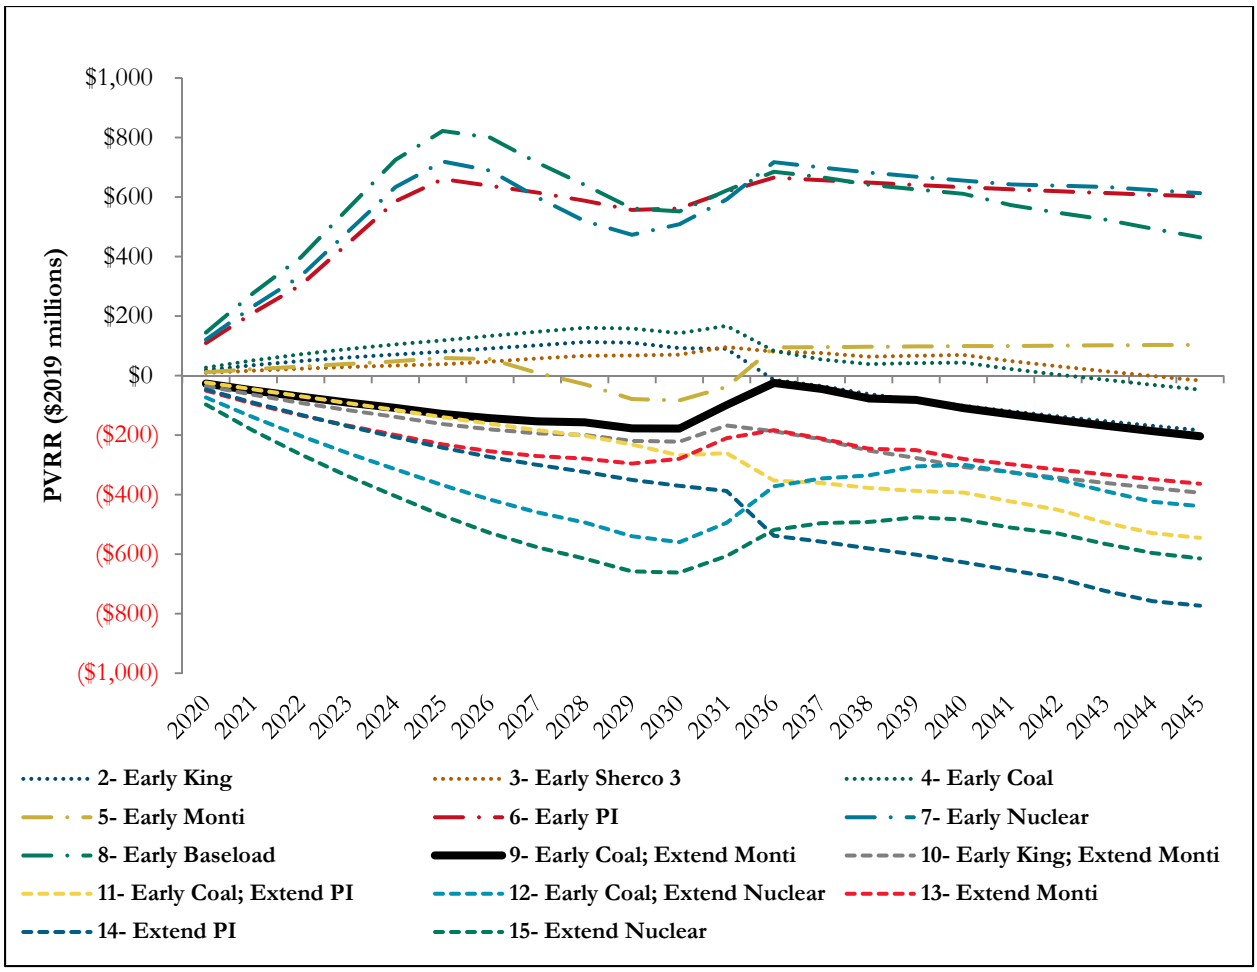
[12] Note that these PVRR and PVSC deltas shown depict NPV for 2020-2045.

Figure 5-8: Scenario PVRR Deltas from Reference Case ($2019 millions)



In addition to evaluating the total NPV of each scenario, we also examine the timing of the relative costs and benefits. Examining NPV over a time series helps us make relative comparisons of changes in costs or benefits at key "transition points" of the plans (such as retirement or extension dates, significant renewable additions, etc.). The cumulative total PVRR costs or savings for each of the scenarios are shown below in Figure 5-9. Each line on the chart illustrates the running total of the annual PVRR costs or benefits by year for a specific scenario, compared to the Reference Case. The end point of the lines in 2045 corresponds to the final PVRR deltas shown in Figure 5-8 above.

Figure 5-9: Cumulative PVRR Cost or Savings Deltas by Scenario, Compared to the Reference Plan ($2019 million)



In addition to PVSC and PVRR, the Company completed sensitivity analyses for all 15 scenarios. The results of these analyses are shown in Appendix F3.

3. Additional Risk Metrics for Baseload Scenario Evaluation

While present value costs are one factor we use to inform our Preferred Plan, we also consider other factors and elements of risk exposure for each potential Scenario. Consistent with the Resource Plan objectives presented in Chapter 4, we evaluated each scenario with regard to achieving our cost, environmental, risk and reliability goals. It is essential that our Preferred Plan meets our carbon reduction goals while also ensuring that the system remains reliable and the plan remains affordable for customers. Likewise, it is important we evaluate various risks, because forecasting into the future is inherently uncertain and we want to ensure our selected Plan

remains robust, even if some key factors change. We describe the objective risk measures we used to evaluate the scenarios in Table 5-3 below.

Table 5-3: Scenario Modeling Portfolio Risk Metrics

Objective	Metric	Definition
Cost	Base PVRR and Base PVSC	Traditional NPV measure of total 2020-2045 PVRR or PVSC costs to determine least cost plan. Plans showing cost savings are preferred.
	Worst Case Futures Scenario Cost	Measure of worst case potential cost outcomes across the four Futures Scenarios so provides insight into plan cost risk. Plans still showing cost savings in worst case Futures Scenario are preferred.
Risk	Energy Risk	Measures the absolute value of average annual total market interaction (purchases plus sales plus dump energy) associated with each plan, to assess market energy risk exposure. Plans with lower market energy exposure are preferred.
	Capacity Risk	Measures average annual net capacity position associated with each plan, to assess market capacity risk exposure. Typically, plans with lower net capacity positions are considered favorable, and our rankings reflect that. However, we also take into account certain factors that are specific to this Resource Plan, which affect the weight we place on this metric. These are discussed further below in Section V.
Environmental	Carbon Emissions Reduction	All plans achieve acceptable levels of carbon reduction, as a result of including an 80 percent carbon reduction (relative to 2005 levels) constraint in modeling.
Reliability	Firm, Dispatchable Resource to Peak Load Ratio	All plans achieve acceptable levels of reliability, measured by the amount of firm, dispatchable resources available, as a result of including the Reliability Requirement in modeling.

As noted, all scenarios meet the environmental and reliability objectives, given these targets are included as constraints in our modeling. Thus, our Scenario evaluation focuses on the cost and risk objective metrics noted above.

V. PREFERRED PLAN SELECTION AND ASSESSMENT

As described previously in this Chapter and in Chapter 4, we evaluated the PVRR and PVSC results of our 15 baseload scenarios, and how effectively each potential plan would meet our planning objectives, to determine which Scenario should form the basis of the Preferred Plan. Based on these outcomes, we selected baseload Scenario 9. Our plan charts the path toward achieving ambitious carbon reduction goals, reflects substantial stakeholder input and consensus, and ensures reliability and

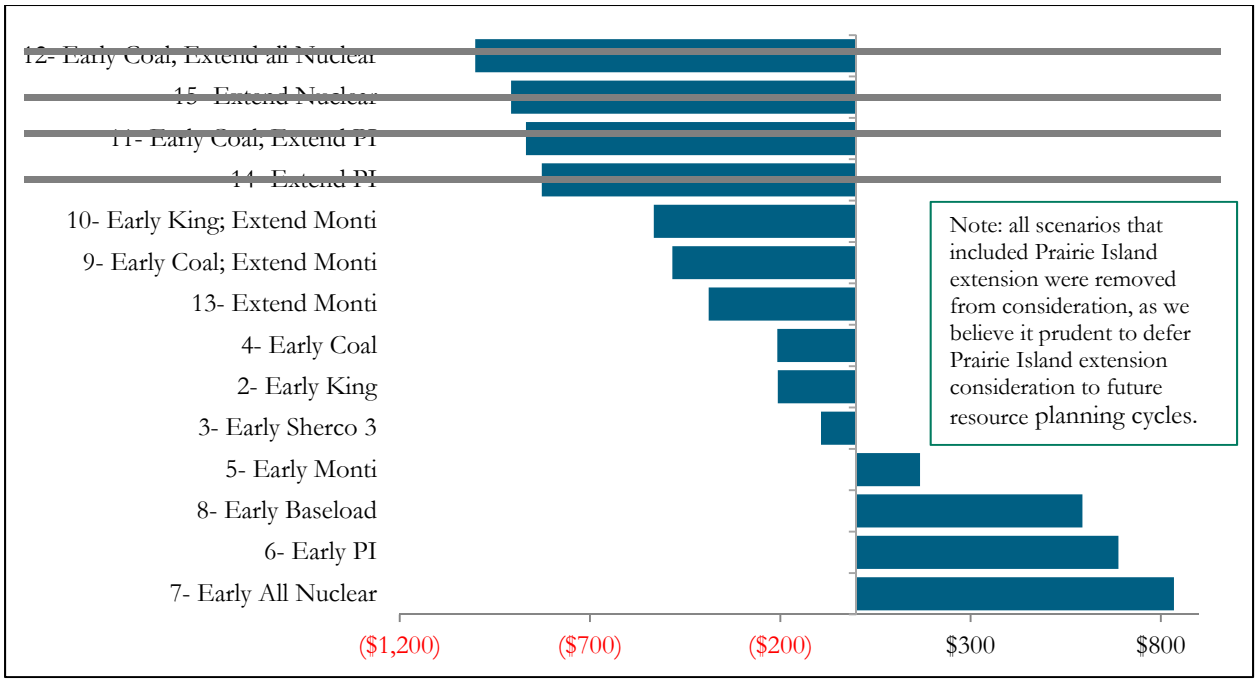
affordability for our customers. The baseload aspects of this plan include an early King retirement in 2028, Sherco 3 early retirement in 2030 and extension of our Monticello nuclear facility to 2040. We also took into account additional considerations regarding DR when finalizing the Preferred Plan. We discuss more detail regarding how we selected and evaluated our Preferred Plan below.

A. Baseload Study Analysis Results

From a modeling perspective, the PVSC and PVRR results are primary indicators of the various scenarios' economic favorability. Figures 5-8 and 5-9 shown above indicate that the nuclear extension scenarios paired with early coal retirements yielded the most attractive customer value relative to the Reference Case.

We note that while Baseload Scenario 9 was not the least cost of our 15 scenarios, several lesser cost scenarios included an extension of Prairie Island's operating license. However, as discussed previously, Prairie Island's license does not expire until the 2033-3034 timeframe just outside the planning period, and we believe there is risk avoidance value in deferring a decision on Prairie Island extension until a future Resource Planning process. As a result, we eliminated from consideration cases that include a Prairie Island extension, as shown below.

Figure 5-10: Scenario PVSC Deltas from Reference Case, PI Extension Cases Eliminated ($2019 millions)



After screening out the baseload scenarios that include Prairie Island extension, we evaluated the remaining scenarios using the cost and risk metrics discussed previously, including savings or costs achieved in a "worst-case" Futures Scenario, and average energy and capacity exposure. Of the remaining baseload scenarios available for selection, Scenarios 9 (Early Coal; Extend Monti), and 10 (Early King; Extend Monti) achieve the most favorable risk profile overall.

Further, Minn. Stat. § 216B.2422, subd. 2(c) requires that we "include the least cost plan for meeting 50 and 75 percent of all energy needs from both new and refurbished generating facilities through a combination of conservation and renewable energy resources." The Preferred Plan (Scenario 9 - Early Coal; Extend Monti) satisfies the statute's first requirement (50 percent of energy needs from conservation or renewables) because it is economically optimized and meets approximately 64 percent of energy needs with renewables and conservation. Our baseload scenario analysis satisfies this statute's second requirement (75 percent of energy needs from conservation or renewables), as Scenario 4 (Early Coal) yields the least cost plan for meeting at least 75 percent of all energy needs from both new and refurbished generating facilities through a combination of conservation and renewable energy resources. Because this scenario does not include a nuclear extension, it enables greater levels of renewable additions than the Preferred Plan that meet or exceed the 75 percent threshold.

B. Early Retirement of Sherco 3 by 2030

Excluding the Prairie Island extension scenarios, Scenarios 9 and 10 become the optimal least cost options. Both Scenarios 9 and 10 assume an early King retirement and Monticello extension; however, Scenario 9 includes an early Sherco 3 retirement while Scenario 10 does not. Both Scenarios are beneficial on a PVSC and PVRR basis, and are the most resilient of the remaining scenarios to the potential worst case evaluated, continuing to maintain customer benefits relative to the Reference case.

Given the proximity of overall customer savings and risk considerations between Scenario 9 and 10, we ultimately considered which case would fit best with our strategic objectives and our understanding of stakeholder interests. We selected Scenario 9 as our Preferred Plan, which includes the retirement of all remaining coal units. Scenario 9 provides the best fit for our carbon goals and helps mitigate the potential for regulatory or legislative action around carbon costs or carbon reduction levels. Further, general market trends toward increasing levels and decreasing costs of renewables, low natural gas prices, the need for more flexible resources, and other factors are expected to make it more and more difficult for coal resources to operate

in an efficient and economic manner beyond 2030. Finally, our interactions with customers, stakeholders, and shareholders alike have shown increasing interest in achievement of carbon reductions and other environmental solutions. From a financial risk perspective, we believe it is beneficial for the Company to reduce carbon risk exposure, and we view transitioning our generation fleet away from coal assets is one of the best ways to achieve that goal.

C. Demand Response Adjustment to Scenario 9

As noted previously, the model optimization exercise did not select any of the DR Bundles provided as options. However, the Order approving our last Resource Plan included direction to add 400 MW of incremental DR resources. Therefore, the final step in developing our Preferred Plan was to include DR Bundle 1 as part of Scenario 9. This addition increases our net long capacity position, where after 2025, our position remains long by a range of 500-1,000 MW through the remainder of the planning period. As mentioned previously, we typically view a long capacity position as less favorable; however, we believe this is an acceptable path forward given alignment with our risk mitigation planning objective, discussed further below.

D. Futures Scenarios Results

As previously discussed, a final step in our analysis process evaluated the performance of the Preferred Plan under the Futures Scenarios. Table 5-4 below provides a summary of the Futures Scenario results. Under all of these Futures Scenarios, the Preferred Plan provides savings relative to the Reference Case,[13] which suggests that the Plan is robust under a range of potential future conditions.

Table 5-4: Preferred Plan NPV Savings under Different Futures Scenarios ($2019 millions)

	Base PVSC	Base PVRR	High Electrification Scenario PVSC	High Distributed Solar Scenario PVSC
Delta	***(461)***	***(203)***	***(81)***	***(51)***

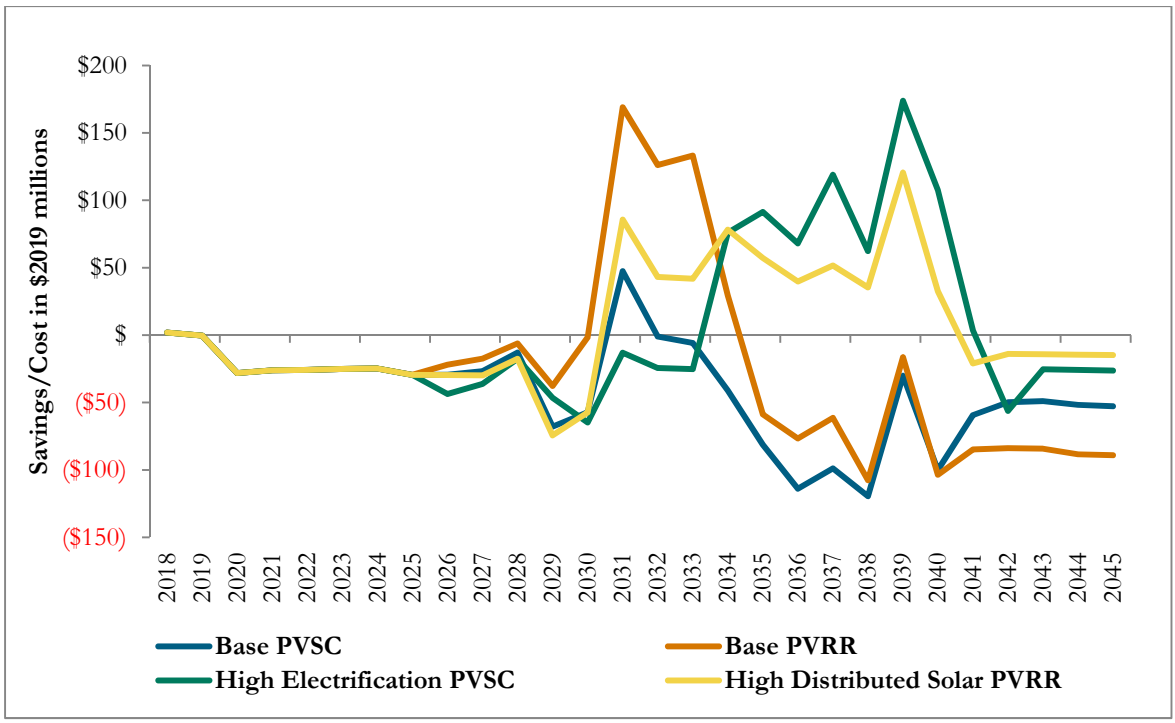
As demonstrated in the baseload scenario analysis and in Table 5-4, the Preferred Plan yields customer value of $203 million in the base PVRR and $461 million in the base PVSC scenarios. Early coal retirements paired with the Monticello extension yield

[13] Note: Each NPV result compares the Preferred Plan with Future Scenarios assumptions applied to the Reference Case with those same assumptions applied.

benefits to customers particularly when carbon costs are included. In both the High Electrification and the High Distributed Solar Futures Scenarios, customer value is marginally reduced from the Base PVRR and PVSC scenarios with $81 million of savings in the High Electrification Scenario and $51 million of savings in the High Distributed Solar Scenario.

As shown in Figure 5-11 below, the Preferred Plan consistently results in customer savings relative to the Reference Case in all Future Scenarios through 2030. At that time, however, the Base PVSC and PVRR scenarios diverge from the High Electrification and High Distributed Solar Scenarios mainly in the 2030 timeframe. A number of factors impact the annual deltas in these Scenarios and drive the divergence. Assumed low new resource capital costs in the Electrification and High Distributed Solar Scenarios likely functions as the biggest driver in upward cost pressure on the Preferred Plan in the 2030s, as in those Scenarios Monticello can be replaced with cheaper renewables. Even under these conditions,, however, the results demonstrate that over the entire planning period and across multiple Futures Scenarios, the Preferred Plan provides overall customer savings relative to the Reference Case. This demonstrates that the Plan is robust and beneficial to customers, yielding savings under a host of potential future conditions.

Figure 5-11: Preferred Plan Annual Costs or Savings Compared to the Reference Case, by Scenario ($2019 millions)



The expansion plans for the Preferred Plan under all of the Futures Scenarios analyses are provided below. In the High Electrification Scenario, higher load growth drives incremental solar and firm dispatchable resource additions above what is included in the Base PVSC/PVRR expansion plans. Specifically, the High Electrification Scenario yields an additional 1,000 MW of solar and 748 MW of firm dispatchable additions. In the High Distributed Solar Scenario, utility-scale solar is displaced by incremental distributed solar, as well as additional EE resources, per the inclusion of the third EE Bundle. Total large solar additions are decreased from 4,000 MW in the base scenarios to 2,500 MW total in the High Distributed Solar Scenario.

Table 5-5: Preferred Plan Base Expansion Plan (MW)

	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034	Total

Table 5-7: High Distributed Solar Scenario Expansion Plan (MW)

	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034	Total
Grid-scale Solar	0	0	0	0	0	500	0	500	500	0	0	500	500	0	0	**2,500**
Battery	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	**0**
CC	0	0	0	0	0	0	0	835	0	0	0	0	0	0	0	**835**
Firm Dispatchable	0	0	0	0	0	0	0	0	0	0	0	606	0	374	748	**1,728**
DR	270	20	21	10	17	41	12	14	15	17	19	20	21	22	23	**542**
EE	151	171	152	174	186	189	202	207	203	185	183	181	171	167	166	**2,687**
Wind	0	0	0	126	45	70	66	72	10	107	16	56	31	523	81	**1,202**
Distributed Solar	154	166	9	11	9	14	93	19	127	27	62	64	67	70	72	**964**

For simplicity, the table below shows cumulative expansion plan additions by resource type. It is important to note that while DR, EE and battery storage are reflected as separate categories, and no incremental additions for these resources are shown, they would be considered to fill any firm dispatchable needs identified in the expansion plans. Similarly, evolving economics and value could also shift the mix of wind and solar additions.

Table 5-8: Cumulative 2020-2034 Additions by Resource Type and Scenario (MW)

	Base Preferred Case	High Electrification	High Distributed Solar
Large Scale Solar	4,000	5,000	2,500
Battery	0	0	0
CC	835	835	835
Firm Dispatchable	1,728	2,476	1,728
DR	542	542	542
EE	2,041	2,041	2,687
Wind	1,202	1,202	1,202
Distributed Solar	442	442	964

E. Preferred Plan Benefits

We believe our analysis supports selection of Scenario 9, including the early retirement of all of our coal resources by 2030 and extension of Monticello nuclear facility to 2040, as our Preferred Plan. While all of our scenarios meet the carbon goal and Reliability Requirement we established, we believe cost and risk considerations elevate Scenario 9 above the rest as an appropriate path forward.

1. Cost

As demonstrated in our modeling analysis, the Preferred Plan achieves customer value, not only under the our Base PVSC ($461 million) and PVRR ($204 million) analysis but also under more challenging future conditions as evidenced in our High Electrification ($81 million) and High Distributed Solar ($51 million) Futures Scenario analysis. In addition, the Preferred Plan yields customer value under all of the individual sensitivities run, even in the Futures Scenario that results in the worst case customer savings outcome (High Distributed Solar Scenario). Lastly, from a customer rate impact perspective, the Preferred Plan results in annual rate increases of just over one (1) percent, which is below the rate of inflation.[14] Altogether, we believe the Preferred Plan delivers tangible customer savings while taking industry-leading steps towards a carbon free future.

2. Risk

In addition to beneficial cost outcomes, the Preferred Plan addresses major risks by maintaining portfolio diversity, retaining optionality and effectively managing market exposure. The Plan incorporates significant capacity additions to replace retiring resources, consisting of a diverse portfolio of DSM, nuclear extension, solar, wind, and firm dispatchable resource additions. Ensuring we do not become too dependent on a single fuel source mitigates risk. In addition, deferring a decision on a potential Prairie Island license extension affords us additional flexibility to reevaluate in future resource planning cycles, as technology costs and other key assumptions can change quickly.

We also evaluate factors such as energy market exposure and portfolio length. All of our baseload scenarios show high levels of market interaction, driven in part by significant renewable additions; but our selected Plan minimizes them relative to other scenarios and attempts to carefully balance and pace renewable additions with other resources. Further, we typically try to achieve a closer supply-demand balance than

[14] As noted in Chapter 4: Preferred Plan and discussed further in Chapter 6: Customer Rate and Cost Impacts

any of our baseload scenarios offer, although the 500-1000 MW of length in any scenario is relatively minimal compared to our overall system. We believe our Preferred Plan's portfolio length is warranted at this time, however, and creates an effective hedge for our customers against two key risk factors:

- *Capital Investment Wind Down At Retiring Plants.* The retirement of all 2,400 MW of our coal assets, in addition to a few other units by 2030 exposes our customers to some risk as we wind down operations and reduce capital spend at these plants. In the event of an early outage, excess capacity will give us the option to flex the retirement dates as needed if we find that a capital investment is not in our customers' best interests at that time.
- *Renewable and Use-Limited Resource Capacity Accreditation.* Solar capacity accreditation is assumed at 50 percent credit in all years of our modeling. We expect this to change as MISO changes its approach to forward capacity accreditation – recognizing that as solar penetration increases in the footprint, the accredited value of solar will decline. The same also applies for use-limited resources like DR. We discuss this emerging MISO recognition in the Baseload Study provided as Appendix J1, in conjunction with the Reliability Requirement in Appendix J2, and in discussion of our Supporting Infrastructure – Transmission & Distribution, provided as Appendix I.

VI. CONCLUSION

Considering the above we believe our modeling and analysis fully supports selection of the Preferred Plan, and strikes a strong balance in meeting our planning objectives, in service of our customers' needs. The plan sets us on a path to deliver tangible savings to our customers, while transitioning our system to meet both our 2030 carbon reduction objectives and longer term carbon-free goals.

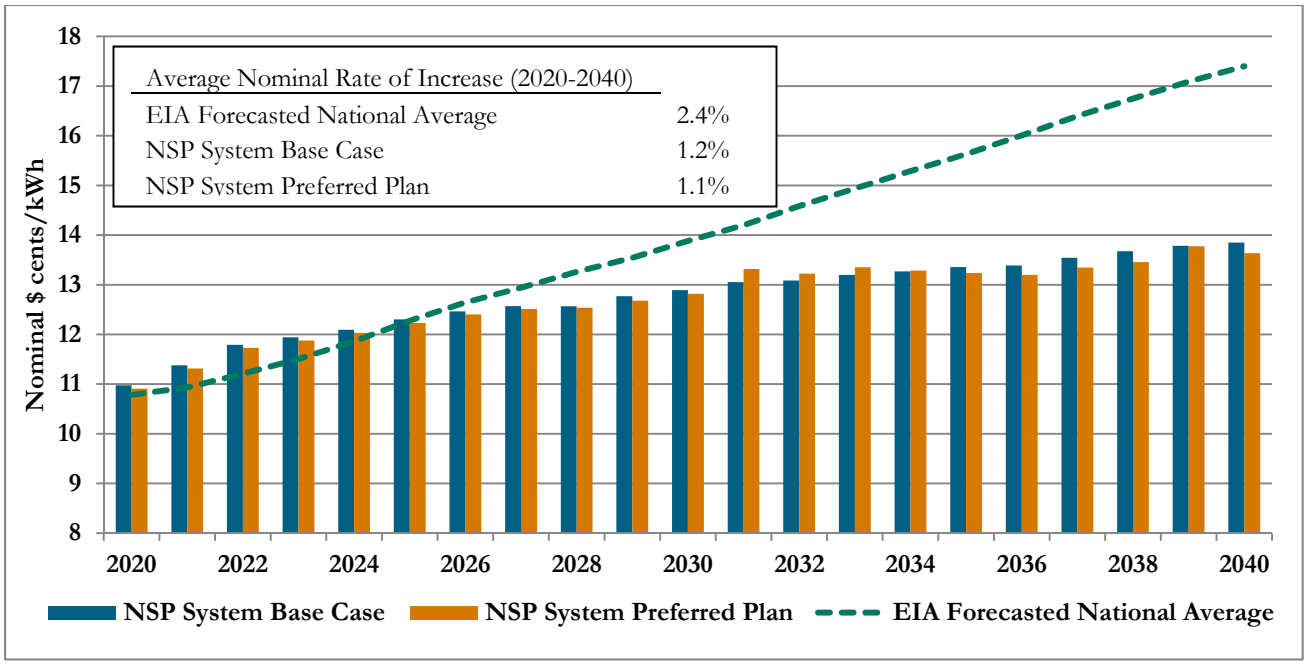
CHAPTER 6
CUSTOMER RATE AND COST IMPACTS

Overall, our Preferred Plan results in an estimated average annual increase in revenue requirements less than the Reference Case and just over one (1) percent overall. In other words, we can achieve significant CO_2 emissions reductions, with cost impacts that are roughly half of the expected national average increase in electricity prices.

Both the Reference Case and the Preferred Plan are designed to meet the Company's goal of reducing carbon emissions 80 percent by 2030, compared to 2005 levels. We did not do the full rate impact calculations discussed in this Chapter on a resource portfolio that does not meet our 80 percent carbon reduction by 2030 goal, we did run a "no 80 by 30" portfolio in our Strategist model and and confirmed that the impacts are in line with our Preferred Plan. In other words, our carbon goals do not materially increase costs for our customers.

To show the cost impact of our proposal over the long-term, we provide a Compound Average Growth Rate (CAGR) comparison of our Preferred Plan compared to the national average nominal cost CAGR for the NSP System in Figure 6-1 and Minnesota in Figure 6-2.

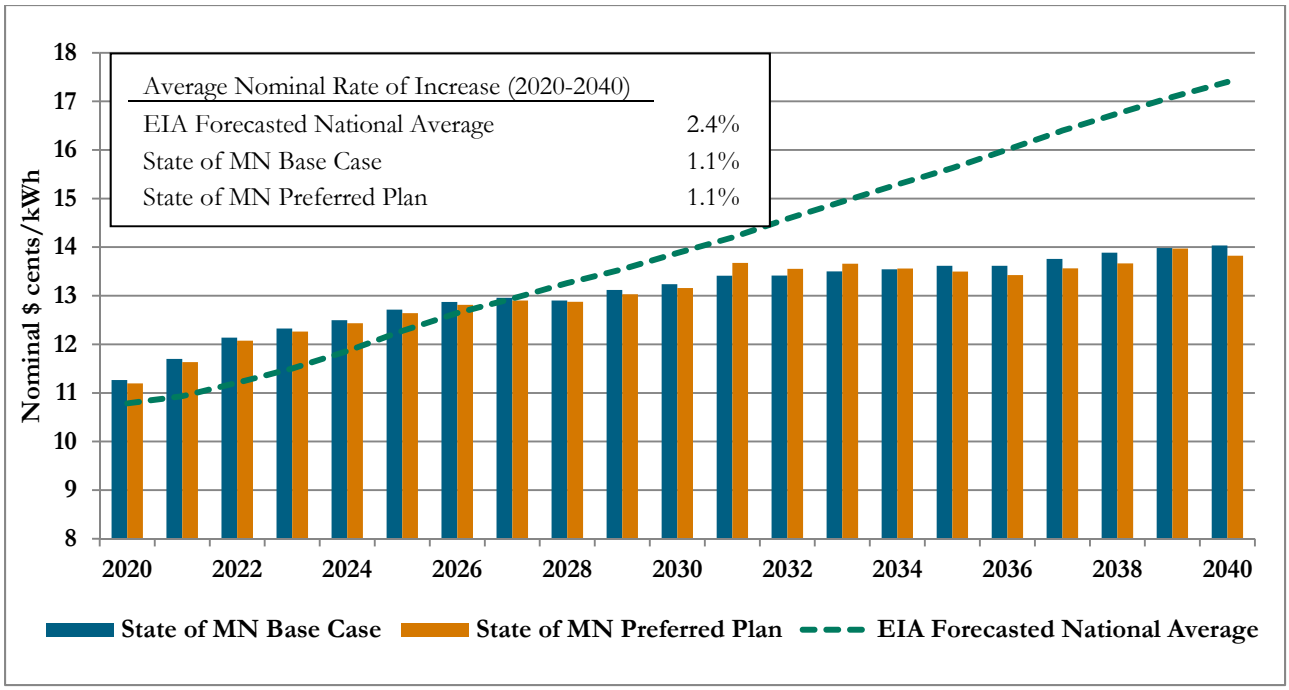
Figure 6-1: Preferred Plan Average Nominal Cost Comparison (NSP System)



* *Notes: National energy cost forecast from Energy Information Administration (EIA) Annual Energy Outlook 2019, Table Energy Supply, Disposition, Prices and Emissions – Reference Case. End use prices, all sector average.*[1] The Preferred Plan and Reference Plan lines include the costs of Solar Rewards*Community.

The report is available at https://www.eia.gov/outlooks/aeo/pdf/aeo2019.pdf.

Figure 6-2: Preferred Plan Average Nominal Cost Comparison (State of Minnesota)



We derived this long-term projection using a combination of a shorter-range financial forecast and the Strategist model.

We note that a detailed analysis of rate impacts in a resource planning process with long-time horizons is difficult to produce due to changes in our rates and resource needs that will occur over time. Because of the simplifying assumptions made in both the calculation methodology and the input variables, these estimated impacts may not correspond with actual rates that the Commission sets for various rate classes in the future. That said, aside from updated inputs to the class cost allocation factors used in this analysis, the methods are the same as those we used in our last Resource Plan.

In this Section, we explain how we approximated a baseline level of revenue requirements associated with our Reference Case and measured the incremental cost impacts of our Preferred Plan at the NSP system, State of Minnesota, and individual State of Minnesota customer class levels. This is generally consistent with the methodology we used in our last Resource Plan.

I. REFERENCE CASE REVENUE REQUIREMENTS FORECAST METHODOLOGY

To calculate the long-term rate impacts of the Preferred Plan as compared to the

Reference Case, we first developed a forecast of total rates under Reference Case assumptions. This forecast leveraged our detailed five-year financial forecast and a specific approach to identify costs through the end of the planning period (2034) using the CAGR of generation and fuel costs from the Strategist model.[2] Next, we analyzed the annual cost differences by category (i.e. fuel, purchased power, capital expenditures, operating and maintenance costs, taxes, depreciation, etc.) from the Strategist model results for the Reference Case and the Preferred Plan to determine the aggregate system cost impacts and jurisdictional and rate class breakouts.

To determine the overall impact to Minnesota customers and individual customer classes in Minnesota, we converted the differential in annual expenses and capital spend of the Preferred Plan compared to the Reference Case into a differential revenue requirement forecast. We then jurisdictionalized the differential revenue requirements and applied class allocation principles to calculate impacts on individual Minnesota customer classes. We provide various rate impact analyses and discuss the methodologies below.

II. ESTIMATED RATE IMPACTS AND METHODOLOGY

The primary Strategist model captures only the generation-related portion of the business, or around 50 percent of the total revenue requirements. Developing a total rate forecast beyond 2023 when detailed Company financial models are not available is dependant on making assumptions for capital expenditures and O&M costs for all areas of the business, including generation (both new and existing), transmission, distribution and corporate support services. Many of these assumptions are speculative, and the resulting total rate forecast would be similarly speculative.

A. Methodology

To calculate the rate impacts of the Preferred Plan, we started with the 2018 budget forecast of total revenue requirements for the 2019-2023 period.[3] To estimate customer impacts for the immediate five-year period, we estimated revenue requirements similar to a Jurisdictional Cost of Service (JCOSS) for each year, and then performed an estimated Class Cost of Service (CCOSS) analysis – both of which required us to make a number of assumptions.

[2] The Strategist model for the Reference Case is the same model used for the Strategist aspect of our Baseload Study, Scenario 1 Reference Case, with the exception that the first Demand Response (DR) bundle was added to the plan, as was also added to the Preferred Plan.
[3] Developed in July 2018 and updated in November 2018.

To determine the JCOSS, we had to make a number of assumptions, including the following:

- Full recovery of the Company's internal five-year forecasts of capital, O&M, and sales,[4]
- Return on Equity (ROE) of 9.20 percent,[5]
- A forecast of debt and equity ratios and debt rates appropriate for the five-year modeling term,
- Estimated historical regulatory adjustments made in rate cases.

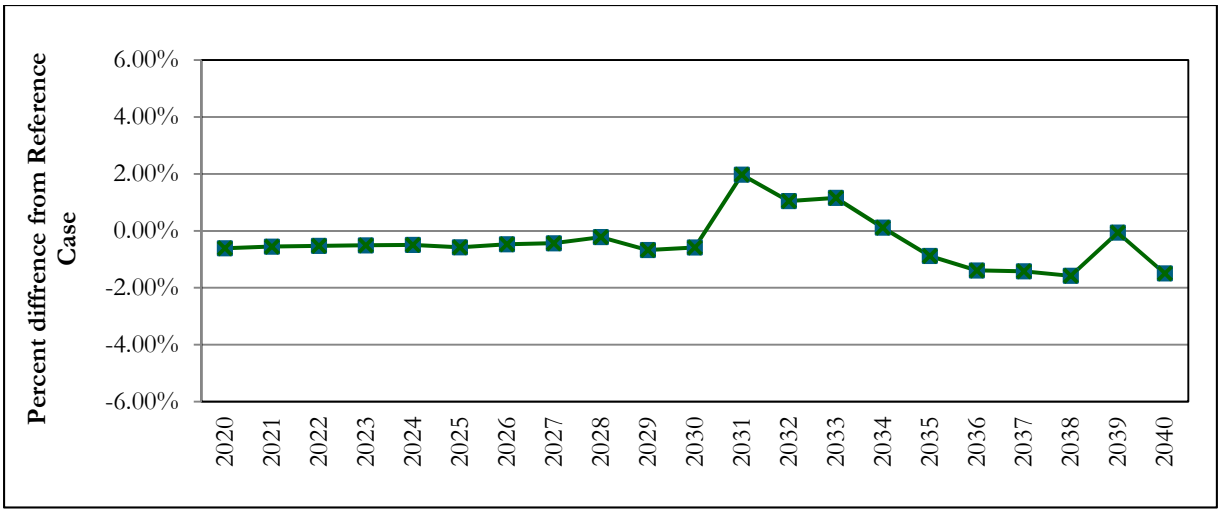
To calculate longer-term rate impacts of the Preferred Plan, we used a combination of the Company's 5-year financial forecast and the Strategist model to project total system revenue requirements for extended periods. For the period beyond 2023, we escalated the capital and O&M costs in the last year of the 5-yr model by the CAGR of the Reference Case as modeled by Strategist.[6] This approach avoids speculation on areas of the business not related to resource planning and modeling, while still using the detailed generation-related information from the Strategist model to create a "business as usual" long term rate projection. Finally, we calculated the annual difference between the Preferred Plan and the Reference Case to estimate the total rate impact of our Preferred Plan.

B. Estimated Overall Rate Impacts

Figure 6-3 below illustrates the State of Minnesota estimated rate impacts of the Preferred Plan compared to the Reference Case over the long-term.

[4] Data as of November 2018.
[5] The Company acknowledges the recent decision in the TCR docket requiring a 9.06% calculation to be used in future filings and will implement that practice once the order is received.
[6] The Reference Case is Resource Plan Scenario 1; see Appendix F2 for additional details.

Figure 6-3: Annual Percent Change in Revenue Requirements (2020-2040)
Preferred Plan above Reference Case – State of Minnesota



The modeling includes accelerated depreciation costs associated with the early retirements of Sherco 3 and King. However, consistent with the Commission's actions in the approval of the early shutdown of the Benson biomass plant (Docket No. E002/M-17-530), a regulatory asset is another tool that could be used to accompany these early retirements. The use of a regulatory asset for the remaining costs of these plants, including a cost of capital return on those assets, would be an appropriate alternative to accelerating the depreciation because it would keep the Company whole over the remainder of the plants' remaining lives. This would also serve to smooth the projected rate impacts over the planning period.

C. Key Drivers

The major inflection points in the delta of revenue requirements (and rates) is driven entirely by the differences in the set of resources that comprise each the Preferred Plan and Reference Case; these points coincide with key differences in baseload plant retirement dates between the two cases and the timing of replacement resources. The reduction in revenue requirements associated with the early coal unit retirements helps to offset a portion of the ongoing nuclear revenue requirements in the Preferred Plan in the early 2030s, as discussed in more detail below:

- *Extension of Monticello.* In 2028, costs associated with the 10-year license extension begin to ramp up in the Preferred Plan, and capital revenue requirements and O&M costs continue through 2040. In contrast, the Reference Case does not have ongoing capital and O&M costs for Monticello beyond 2030 as it is retired in that case; this results in an approximate $295 million difference between the two cases in fixed costs for Monticello,

beginning in 2031.

- *Retirement of Coal Units.* The Reference Case contains ongoing capital and O&M costs for King and Sherco Unit 3, whereas in the Preferred Plan the costs for King terminate in 2029 and Sherco Unit 3 in 2031 due to early retirement. This results in savings of approximately $45 million in fixed costs in 2029, increasing to $110 million in 2031.
- *Load Supporting Resources.* The Preferred Plan has some load-supporting, dispatchable resources added in the early 2030's associated with the Reliability Requirements Proxy discussed in the Baseload Study in this Resource Plan. With the early retirement of King and Sherco Unit 3, the Preferred Plan has a load supporting, dispatchable resource deficiency of approximately 400 MW in that time frame. The Preferred Plan extension of Monticello helps to offset some of this capacity deficiency. The net cost of the load supporting, dispatchable resources in those years ranges from approximately $35 million to $70 million.

The rate increase seen in 2031-2033 reverses in 2034 and the Preferred Plan remains an annual savings producer thereafter. The cost savings from the Preferred Plan are due to the extension of Monticello, which maintains the NSP system 80 percent carbon reduction after Prairie Island retires, without the need to add significant renewables. In the Reference Case, the model adds 2,250 MW of wind in 2034-35 to maintain the 80 percent carbon reduction level, which adds significant costs.

D. These Estimates are not Directly Comparable to Rate Impact Analysis in a Rate Case

We caution that this information should not be interpreted as directly comparable to the customer rate impact information we would provide as part of a rate case filing for reasons including the following:

- The internal forecast for 2019-2023 is not prepared at the level of detail necessary to support a rate case,
- While the forecast includes typical regulatory adjustments, we have not attempted to remove one-time effects or other one-time adjustments that are not specifically known at this time,
- We have made no assumptions of a rate case filing schedule over this period; the forecast provided assumes full recovery of annual deficiencies, suggesting a full rate case annually, and
- All factors of the Cost of Capital, including debt rates, return on equity, and

debt-equity ratios, are subject to change over the period.

III. ESTIMATED RATE IMPACTS BY CLASS PER YEAR

After determining the incremental revenue requirement impacts from the Preferred Plan and Reference Case for the Minnesota jurisdiction, we determined *class* revenue requirement impacts. We provide the estimated impacts below, then discuss the methodology and calculations that we used. The incremental revenue requirement impact of the Preferred Plan versus the Reference Case is shown in column 3 of Table 6-1 below. Column 4 of the below Table also shows the incremental impact of the Preferred Plan as a percent of the total State of Minnesota revenue requirement.

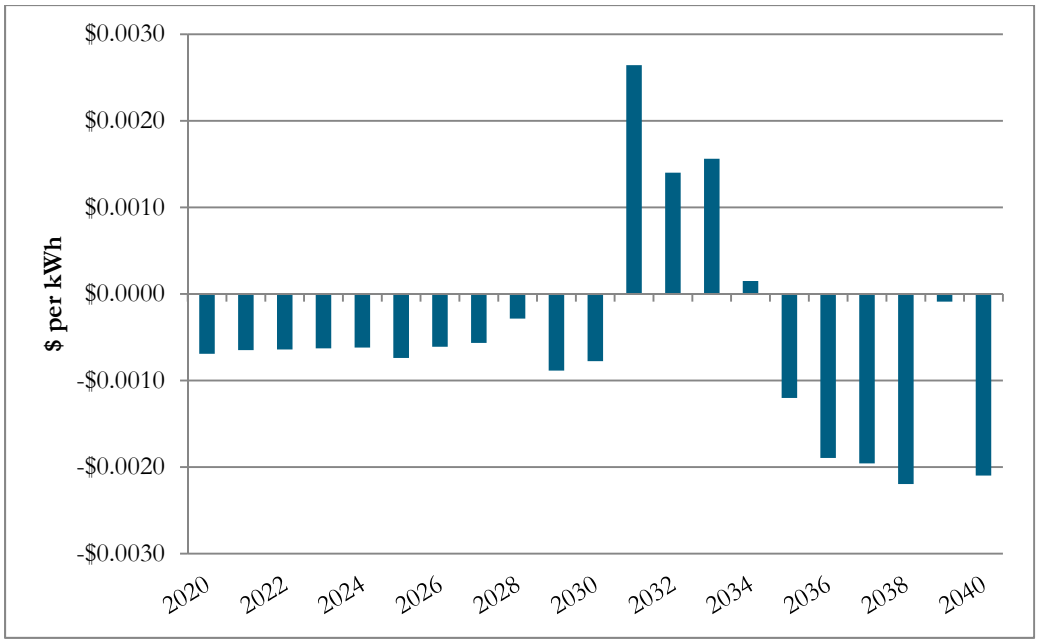
We calculated rate impacts in $ per kWh by dividing each class's revenue requirement in each year by the forecasted sales in each year.

Table 6-1: Estimated Incremental Impact of Preferred Plan
State of Minnesota – All Customers

1	2	3	4
Year	**State of MN Total Revenue Req ($000)**	**Incremental Impact of Preferred Resource Plan** ($000)	**Incremental Impact (%)**
2019	$3,241,019		
2020	$3,309,662	-$20,307	-0.61%
2021	$3,407,431	-$18,905	-0.55%
2022	$3,531,080	-$18,646	-0.53%
2023	$3,567,006	-$18,163	-0.51%
2024	$3,614,422	-$17,880	-0.49%
2025	$3,662,468	-$21,259	-0.58%
2026	$3,711,153	-$17,597	-0.47%
2027	$3,760,484	-$16,389	-0.44%
2028	$3,810,472	-$8,389	-0.22%
2029	$3,861,124	-$26,054	-0.67%
2030	$3,912,450	-$22,932	-0.59%
2031	$3,964,457	$78,174	1.97%
2032	$4,017,157	$41,948	1.04%
2033	$4,070,556	$47,089	1.16%
2034	$4,124,665	$4,568	0.11%
2035	$4,179,494	-$36,862	-0.88%
2036	$4,235,052	-$58,945	-1.39%
2037	$4,291,348	-$61,023	-1.42%
2038	$4,348,392	-$68,746	-1.58%
2039	$4,406,195	-$2,809	-0.06%
2040	$4,464,766	-$66,728	-1.49%

We visually portray this information in Figure 6-4 below.

Figure 6-4: Incremental Rate Impact of Preferred Plan
State of Minnesota – All Customers



A. Methodology and Calculations

We determine class revenue requirement impacts by allocating incremental costs to rate classes for each year in the planning period (2020-2034). After costs are allocated, we then calculate revenue requirement impacts for each customer class.

We apply ratemaking treatments to expense items that are impacted by the Resource Plan, as follows:

- Fuel Costs
- Purchased Energy
- Production O&M Expenses
- Property Taxes
- Deferred Income Taxes
- Tax Depreciation and Removal Expense,
- Decommissioning Accruals
- Plant In Service and Associated Depreciation, Construction Work in Progress (CWIP), and Accumulated Deferred Income Taxes

- Bulk Transmission Costs

We discuss our treatment of these expense items for purposes of this rate impact analysis below.

B. Fuel Costs and Purchased Energy

Fuel and purchased energy costs are allocated to classes using the E8760 energy allocator approved in our most recent Minnesota rate case, as provided below:[7]

Table 6-2: E8760 Energy Allocator

MN	Residential	Commercial Non-Demand	C&I Demand	Lighting
100.00%	29.27%	3.04%	67.24%	0.44%

The E8760 allocator is calculated by taking the forecast hourly load for each of the 8,760 hours of the test year for each customer class, then weighting the hourly load by the forecasted hourly marginal energy cost in each respective hour.

C. Production Expense, Property Taxes, Deferred Income Taxes, Tax Depreciation and Removal Expense and Decommissioning Accrual

These expense items are split into energy-related and capacity/demand-related components using the Company's plant stratification analysis approved in our most recent Minnesota rate case.[8] We provide the approved plant stratification analysis that we applied to production O&M expenses for each plant type below:

[7] See Docket No. E002/GR-15-826, *In the Matter of the Application of Northern States Power Company for Authority to Increase Rates for Electric Service in the State of Minnesota*, FINDINGS OF FACT, CONCLUSIONS, AND ORDER, (June 12, 2017).
[8] *Id.*

Table 6-3: Stratification Analysis by Plant Type

Plant Type	Replacement Value $/kW	Capacity Ratio	Capacity/Demand Percentage	Energy Percentage
Combustion Turbine	$825	$825 / $825	100.0%	0.0%
Fossil	$2,089	$825 / $2,089	39.5%	60.5%
Nuclear	$4,286	$825 / $4,286	19.3%	80.7%
Combined Cycle	$1,079	$825 / $1,079	76.5%	23.5%
Wind	$15,847	$825 / $15,847	5.2%	94.8%
Solar	$8,182	$825 / $8,182	10.1%	89.9%

The plant stratification approach begins by comparing the replacement cost of each type of generation plant (fossil, combined cycle, nuclear, etc.) to the replacement cost of a CT. CT are 100 percent capacity/demand-related since they are the generation source with the lowest capital cost and the highest operating cost. For each generation type, the percent of total generation costs that exceeds the cost of a CT peaking plant are classified as being energy-related. These costs are in excess of the capacity/demand-related portion, and as such, were not incurred to obtain capacity, but rather to obtain lower cost energy.

After production O&M costs originating from each type of generation plant are split into capacity-related and energy-related components based on the percentages shown in Table 6-3 above, those costs that have been classified as being energy-related are allocated to class using the E8760 energy allocator provided in *part 1* above.

The capital costs that have been classified as being capacity- or demand-related are allocated to customer class using the D10S capacity allocator approved by the Commission in our most recent rate case.[9] The D10S allocator is simply each class's load that is coincident with the NSP system peak load. We provide the approved D10S class allocator percentages below:

Table 6-4: D10S Capacity Allocator

MN	Residential	Commercial Non-Demand	C&I Demand	Lighting
100.00%	36.14%	3.28%	60.59%	0.00%

[9] *Id.*

D. Generation Rate Base Costs Including Plant in Service, Depreciation, CWIP and Accumulated Deferred Income Taxes

Rate base related costs from each type of generation plant are also split into energy-related and capacity/demand-related components using the Company's plant stratification analysis approved in our most recent Minnesota rate case.[10] As was true with the expense items listed in *part 2* above, rate base costs classified as being energy-related are allocated to class using the E8760 energy allocator. Likewise, the capital costs that have been classified as being capacity or demand-related are allocated to customer class using the D10S capacity allocator.

E. Bulk Transmission Costs

As ordered by the Minnesota Commission, all rate base and expense items related to bulk transmission are classified as being capacity or demand-related and are allocated to customer class using the Commission-approved D10S capacity allocator.[11]

IV. DETERMINING CLASS RATE IMPACTS

In order to show the estimated impacts of the Preferred Plan on customer rates and bills, we provide a breakdown by customer class for the 2020-2040 period, and in more detail for the immediate five-year 2019-2023 period at the Minnesota customer class levels.

Figure 6-5 below shows the estimated incremental impacts of our Preferred Plan over the long-term by customer class.

[10] *Id.*
[11] *Id.*

Figure 6-5: Incremental Rate Impact of Preferred Plan by Customer Class – State of Minnesota

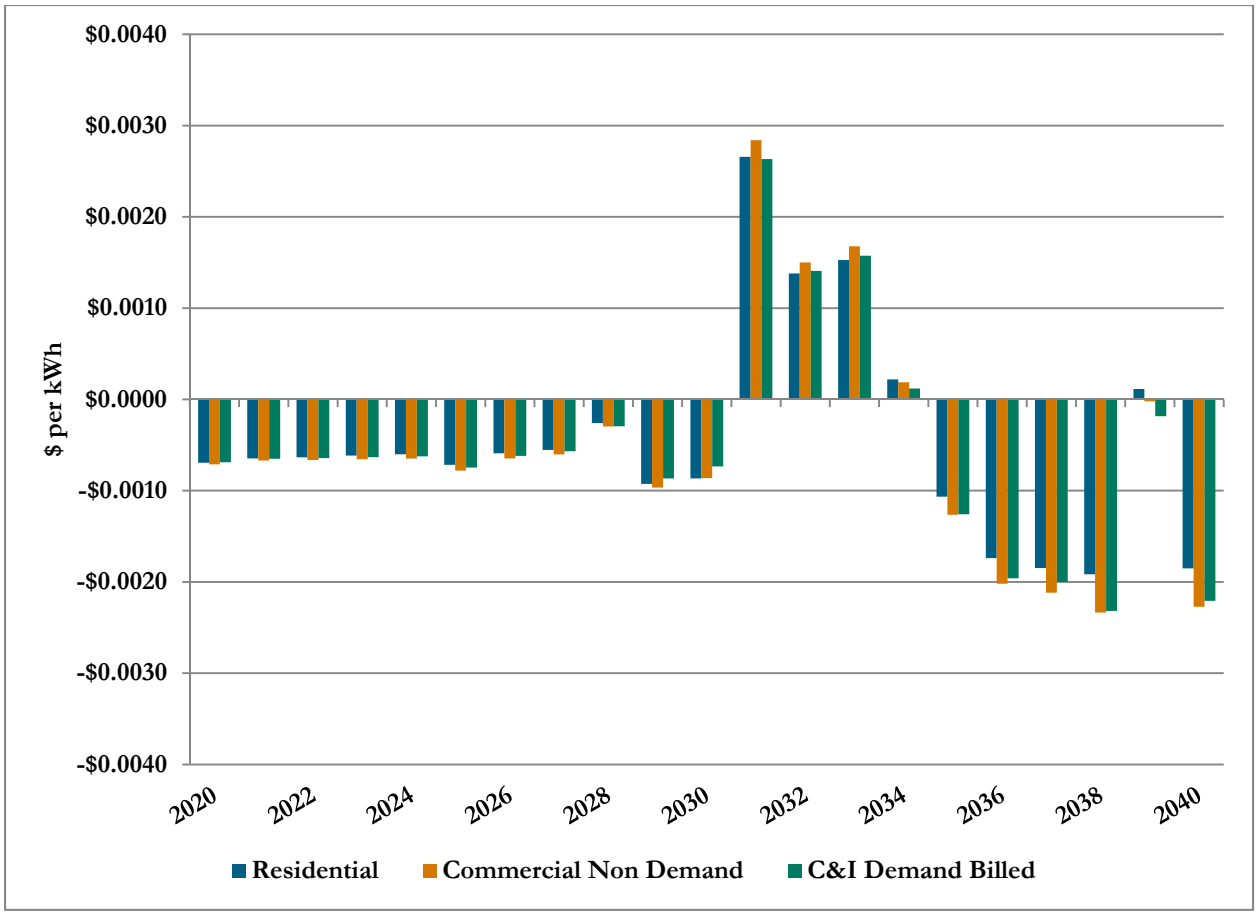


Table 6-5 below provides a more detailed view of near-term estimated rate impacts for Minnesota customer classes.

Table 6-5: Preferred Plan Estimated Rate Impacts by Class per Year

Rate Class Impacts \1	2019	2020	2021	2022	2023	2024	Comp'd Incr/Yr
Residential (avg rate, ¢/kWh)	14.488¢	14.367¢	14.506¢	14.847¢	15.377¢	15.526¢	N/A
Cumul Increase (¢/kWh)		-0.121	0.018	0.359	0.889	1.037	N/A
Cumulative Increase (%)		-0.84%	0.12%	2.48%	6.14%	7.16%	1.39%
$ Impact/Month, @ 650	($0.79)	$0.11	$2.33	$5.78	$6.74	N/A	N/A
Sm Non-Dmd (avg rate, ¢/kWh)	13.218¢	13.218¢	13.167¢	13.511¢	13.946¢	14.599¢	14.855¢
Cumul Increase (¢/kWh)		-0.052	0.293	0.727	1.380	1.636	N/A
Cumulative Increase (%)		-0.39%	2.22%	5.50%	10.44%	12.38%	2.36%
$ Impact/Month, @ 1,000	($0.52)	$2.93	$7.27	$13.80	$16.36	N/A	N/A
Demand (avg rate, ¢/kWh)	9.370¢	9.300¢	9.707¢	10.040¢	10.471¢	10.570¢	N/A
Cumul Increase (¢/kWh)		-0.070	0.336	0.669	1.100	1.199	N/A
Cumulative Increase (%)		-0.75%	3.59%	7.14%	11.74%	12.80%	2.44%
$ Impact/Month, @ 37,500	($26.30)	$126.15	$250.98	$412.56	$449.71	N/A	N/A
Street Ltg (avg rate, ¢/kWh)	25.290¢	25.027¢	24.668¢	24.917¢	25.624¢	26.079¢	N/A
Cumul Increase (¢/kWh)		-0.262	-0.622	-0.372	0.334	0.790	N/A
Cumulative Increase (%)		-1.04%	-2.46%	-1.47%	1.32%	3.12%	0.62%
$ Impact/Month, @ 60	($0.16)	($0.37)	($0.22)	$0.20	$0.47	N/A	N/A

Using the methodologies described above, the incremental costs in the last year of the period (2024) for the Preferred Plan would be expected to increase the average Residential rate by about 1.39 percent on a compounded annual basis through 2024. That is equivalent to a total increase of $6.74 per month above the current rate level.

The impact to the average Large Demand Billed rate would be an increase of about 2.44 percent on a compounded annual basis through 2023, which is equivalent to an increase of 1.199 cents per kWh above the 2019 level.

V. FACTORS IMPACTING NEAR-AND LONG-TERM RATE ESTIMATES

We note that the following factors could have an impact on the estimated rate impacts in the planning period:

Depreciation Expense for Coal Closures. The modeling and estimated rate impacts reflect accelerated depreciation associated with the early retirement of the Allen S. King and Sherco Unit 3 plants. This is consistent with the Company's current method of recovery for Sherco 1 and 2. As noted previously, however, and consistent with the Commission's actions in the approval of the early shutdown of the Benson biomass plant, a regulatory asset is another tool that could be used to accompany these early retirements. An alternative regulatory treatment such as this would impact this analysis.

Generation Ownership: Owned and Purchased Power Agreement resources will have different cost patterns, which will impact this analysis to the extent a resource addition differs in terms of ownership from what was modeled.

Taxes. This analysis is based on present tax conditions. Any tax changes will impact the modeling underlying this analysis and thus the rate impact results.

Nuclear Decommissioning Trust. There are several items regarding the NDT that may have a material impact on costs included in this resource plan.

Pending or Future Regulatory Decisions. Rate case and resource acquisition outcomes have the potential to impact rates and system needs.

Large Customer Changes. The loss or addition of a large business customer has the potential to impact both rates and system needs.

CERTIFICATE OF SERVICE

APPENDIX A - COMPLIANCE MATRIX

Xcel Energy is committed to complying fully with all applicable statutes and rules and we believe our Plan reflects appropriate implementation of all requirements. We have prepared a matrix reflecting our inventory of requirements to be met in this Application and cross-referenced to the portion of the Plan that fulfills each compliance item.

Rules, Statutes, and Orders

Statute, Rule or Order	Subdivision or Order Point	Information Required by Statute	(7/1/2019) 2020-2034 IRP Location of Required Content
Minn. Stat. §216B.1691 Renewable Energy Objectives	Subdivision 2e.	Rate impact of standard compliance; report. Each electric utility must submit to the commission and the legislative committees with primary jurisdiction over energy policy a report containing an estimation of the rate impact of activities of the electric utility necessary to comply with this section. In consultation with the Department of Commerce, the commission shall determine a uniform reporting system to ensure that individual utility reports are consistent and comparable, and shall, by order, require each electric utility subject to this section to use that reporting system. The rate impact estimate must be for wholesale rates and, if the electric utility makes retail sales, the estimate shall also be for the impact on the electric utility's retail rates. Those activities include, without limitation, energy purchases, generation facility acquisition and construction, and transmission improvements. After the initial report, a report must be updated and submitted as part of each integrated resource plan or plan modification filed by the electric utility under section 216B.2422.	Appendix N5: Biennial Report: Renewable Energy Obligation-Renewable Energy Standard Compliance Report Appendix N6: Renewable Energy Standard: Rate Impact Report
Minn. Stat. §216B.1691 Renewable Energy Objectives	Subdivision 3.	Utility plans filed with commission. (a) Each electric utility shall report on its plans, activities, and progress with regard to the objectives and standards of this section in its filings under section 216B.2422, demonstrating to the commission the utility's effort to comply with this section. In its resource plan, each electric utility shall provide a description of: (1) the status of the utility's renewable energy mix relative to the objective and standards; (2) efforts taken to meet the objective and standards; (3) any obstacles encountered or anticipated in meeting the objective or standards; and (4) potential solutions to the obstacles.	Chapter 3: Minimum System Needs Appendix N4: Renewable Energy Compliance Positions Appendix N5: Biennial Report: Renewable Energy Obligation-Renewable Energy Standard Compliance Report
Minn. Stat. §216B.1691 Renewable Energy Objectives	Subdivision 10.	"Utility acquisition of resources. A competitive resource acquisition process established by the commission prior to June 1, 2007, shall not apply to a utility for the construction, ownership, and operation of generation facilities used to satisfy the requirements of this section unless, upon a finding that it is in the public interest, the commission issues an order on or after June 1, 2007, that requires compliance by a utility with a competitive resource acquisition process. A utility that owns a nuclear generation facility and intends to construct, own, or operate facilities under this section shall file with the commission on or before March 1, 2008, a renewable energy plan setting forth the manner in which the utility proposes to meet the requirements of this section. The utility shall update the plan as necessary in its filing under section 216B.2422. The commission shall approve the plan unless it determines, after public hearing and comment, that the plan is not in the public interest. As part of its determination of public interest, the commission shall consider the plan's impact on balancing the state's interest in: (1) promoting the policy of economic development in rural areas through the development of renewable energy projects, as expressed in subdivision 9; (2) maintaining the reliability of the state's electric power grid; and (3) minimizing cost impacts on ratepayers."	N/A - we are not proposing any specific resource acquisitions in this Resource Plan
Minn. Stat. §216B.2422. Resource Planning; Renewable Energy	Subdivision 2.	(c) As a part of its resource plan filing, a utility shall include the least cost plan for meeting 50 and 75 percent of all energy needs from both new and refurbished generating facilities through a combination of conservation and renewable energy resources.	Chapter 5: Economic Modeling Framework
Minn. Stat. §216B.2422. Resource Planning; Renewable Energy	Subdivision 2a.	Historical data and Advance Forecast. Each utility required to file a resource plan under this section shall include in the filing all applicable annual information required by section 216C.17, subdivision 2, and the rules adopted under that section. To the extent that a utility complies with this subdivision, it is not required to file annual advance forecasts with the department under section 216C.17, subdivision 2.	Appendix N1: Annual Report: Minnesota Electric
Minn. Stat. §216B.2422. Resource Planning; Renewable Energy	Subdivision 2c.	Long-range emission reduction planning. Each utility required to file a resource plan under subdivision 2 shall include in the filing a narrative identifying and describing the costs, opportunities, and technical barriers to the utility continuing to make progress on its system toward achieving the state greenhouse gas emission reduction goals established in section 216H.02, subdivision 1, and the technologies, alternatives, and steps the utility is considering to address those opportunities and barriers.	Chapter 4: Preferred Plan Appendix H: Environmental Regulations Review

Statute, Rule or Order	Subdivision or Order Point	Information Required by Statute	(7/1/2019) 2020-2034 IRP Location of Required Content
Minn. Stat. §216B.2422. Resource Planning; Renewable Energy	Subdivision 3.	Environmental Costs. (a) A utility shall use the values established by the commission in conjunction with other external factors, including socioeconomic costs, when evaluating and selecting resource options in all proceedings before the commission, including resource plan and certificate of need proceedings.	Chapter 5: Economic Modeling Framework Appendix F2: Strategist Modeling Assumptions & Inputs
Minn. Stat. §216B.2422. Resource Planning; Renewable Energy	Subdivision 4.	Preference for renewable energy facility. The commission shall not approve a new or refurbished nonrenewable energy facility in an integrated resource plan or a certificate of need, pursuant to section 216B.243, nor shall the commission allow rate recovery pursuant to section 216B.16 for such a nonrenewable energy facility, unless the utility has demonstrated that a renewable energy facility is not in the public interest. When making the public interest determination, the commission must consider: (1) whether the resource plan helps the utility achieve the greenhouse gas reduction goals under section 216H.02, the renewable energy standard under section 216B.1691, or the solar energy standard under section 216B.1691, subdivision 2f.; (2) impacts on local and regional grid reliability; (3) utility and ratepayer impacts resulting from the intermittent nature of renewable energy facilities, including but not limited to the costs of purchasing wholesale electricity in the market and the costs of providing ancillary services; and (4) utility and ratepayer impacts resulting from reduced exposure to fuel price volatility, changes in transmission costs, portfolio diversification, and environmental compliance costs.	Chapter 4: Preferred Plan Chapter 5: Economic Modeling Framework Appendix F2: Strategist Modeling Assumptions & Inputs
Minn. Stat. §216B.2422. Resource Planning; Renewable Energy	Subdivision 7.	Energy storage systems assessment. (a) Each public utility required to file a resource plan under subdivision 2 must include in the filing an assessment of energy storage systems that analyzes how the deployment of energy storage systems contributes to: (1) meeting identified generation and capacity needs; and (2) evaluating ancillary services. (b) The assessment must employ appropriate modeling methods to enable the analysis required in paragraph (a).	Appendix F7: Minnesota Energy Storage Systems Assessment
Minn. Stat. §216B.2426. Opportunities for Distributed Generation		The commission shall ensure that opportunities for the installation of distributed generation, as that term is defined in section 216B.169, subdivision 1, paragraph (c), are considered in any proceeding under section 216B.2422, 216B.2425, or 216B.243.	Chapter 5: Economic Modeling Framework
Minn. Stat. §3.8851 Legislative Energy Commission	Subdivision 4.	Nuclear reports. The public utility that owns the Prairie Island and Monticello nuclear generation facilities shall update the reports required under section 116C.772, subdivisions 3 to 5, and shall submit those updates periodically to the Public Utilities Commission with the utility's resource plan filing under section 216B.2422 and to the Legislative Energy Commission.	Appendix N9: Triennial Filing: Nuclear Decommissioning Appendix N10: Nuclear Worker Transition Plan
Minn. Rule 7843.0300, Filing Requirements and Procedures	Subpart 3.	*Completeness of filing*. The resource plan must contain the information required by part 7843.0400, unless an exemption has been granted under subpart 4.	See below:
Minn. Rule 7843.0400. Contents of Resource Plan Filings	Subpart 1.	*Advance forecasts*. A utility shall include in the filing identified in Subpart 2 its most recent annual submission to the Minnesota Department of Commerce and the Minnesota Environmental Quality Board under Minnesota Statutes, sections 216B.2422, subdivision 2a, and 216C.17, and parts 7610.0000 to 7610.0600.	Appendix N1: Annual Report: Minnesota Electric
Minn. Rule 7843.0400. Contents of Resource Plan Filings	Subpart 2.	*Resource Plan*. A utility shall file a proposed plan for meeting the service needs of its customers over the forecast period. The plan must show the resource options the utility believes it might use to meet those needs. The plan must also specify how the implementation and use of those resource options would vary with changes in supply and demand circumstances. Utility is only required to identify a resource option generically, unless a commitment to a specific resource exists at the time of the filing. Utility shall also discuss plans to reduce existing resources through sales, leases, deratings, or retirements.	Chapter 4: Preferred Plan Chapter 5: Economic Modeling Framework Appendix F3: Scenario Sensitivity Analysis: PVRR and PVSC Summary
Minn. Rule 7843.0400. Contents of Resource Plan Filings	Subpart 3.	*Supporting Information. A utility shall include in its resource plan filing information supporting selection of the proposed resource plan.*	Chapter 4: Preferred Plan Chapter 5: Economic Modeling Framework Appendix F2: Strategist Modeling Assumptions & Inputs

Statute, Rule or Order	Subdivision or Order Point	Information Required by Statute	(7/1/2019) 2020-2034 IRP Location of Required Content
Minn. Rule 7843.0400. Contents of Resource Plan Filings	Subpart 3A	A) When a utility's existing resources are inadequate to meet the projected level of resource needs, the supporting information must contain a complete list of resource options considered for addition to the existing resources. At a minimum, the list must include new generating facility of various types and sizes and with various fuel types, cogeneration, new transmission facilities of various types and sizes, upgrading of existing generation and transmission equipment, life extensions of existing generation and transmission equipment, load-control equipment, utility-sponsored conservation programs, purchases from non-utilities, and purchases from other utilities. The utility may seek additional input from the commission regarding the resource options to be included in the list. For a resource option that could meet a significant part of the need identified by the forecast, the supporting information must include a general evaluation of the option, including its availability, reliability, cost, socioeconomic effects, and environmental effects.	Chapter 4: Preferred Plan Chapter 5: Economic Modeling Framework Appendix F6: Resource Option Appendix G1: Demand Side Management Appendix I: Supporting Infrastructure: Transmission & Distribution
Minn. Rule 7843.0400. Contents of Resource Plan Filings	Subpart 3B	B) The supporting information must include descriptions of the overall process and of the analytical technique used by the utility to create its proposed resource plan from the available options.	Chapter 5: Economic Modeling Framework Appendix F2: Strategist Modeling Assumptions & Inputs
Minn. Rule 7843.0400. Contents of Resource Plan Filings	Subpart 3C	C) The supporting information must include an action plan, a description of the activities the utility intends to undertake to develop or obtain noncurrent resources identified in its proposed plan. Action plan must cover a five-year period beginning with the filing date. Action plan must include a schedule of key activities, including construction and regulatory filings.	Chapter 4: Preferred Plan
Minn. Rule 7843.0400. Contents of Resource Plan Filings	Subpart 3D	D) For the proposed resource plan as a whole, the supporting information must include a narrative and quantitative discussion of why the plan would be in the public interest, considering the factors listed in part 7843.0500, subpart 3.	Chapter 4: Preferred Plan
Minn. Rule 7843.0400. Contents of Resource Plan Filings	Subpart 4.	Nontechnical summary. A utility shall include in its resource plan filing a non-technical summary, not exceeding 25 pages in length and describing the utility's resource needs, the resource plan created by the utility to meet those needs, the process and analytical techniques used to create the plan, activities required over the next five years to implement the plan, and the likely effect of plan implementation on electric rates and bills. Minn. Stat. §216B.1612,	Appendix D: Non-Technical Summary
Docket No. E999/CI-06-159 *In the Matter of Commission Investigation and Determination under the Electricity Title, Section XII, of the Federal Energy Policy Act of 2005* **August 10, 2007 Order**	Order Point 2.	(Fossil Fuel Efficiency Standard) Investor-owned utilities shall include information in their Resource Plans generically describing how the utility is planning to address fossil fuel efficiency to meet the goals of this standard.	Appendix F2: Strategist Modeling Assumptions & Inputs Attachment A
Docket No. E999/CI-06-159 *In the Matter of Commission Investigation and Determination under the Electricity Title, Section XII, of the Federal Energy Policy Act of 2005* **August 10, 2007 Order**	Order Point 3.	Investor-owned utilities shall include information in their Resource Plans with respect to: a. The heat rates of existing plants; b. Their efforts to maintain or improve heat rates over time; and c. Modeling runs(s) of ways to improve the heat rates of either the largest existing or the lowest heat rate generation plants.	Appendix F2: Strategist Modeling Assumptions & Inputs Attachment A
Docket No. E-002/RP-10-825 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2011-2025 Resource Plan **August 5, 2013 Notice**	Page 1	The public interest determination must include whether the resource plan helps the utility achieve the greenhouse gas reduction goals under section 216H.02, the renewable energy standard under section 216B.1691, or the solar energy standard under section 216B.1691, 2f.	Chapter 4: Preferred Plan Appendix H: Environmental Regulations Review Appendix N4: Renewable Energy Compliance Positions Appendix N5: Biennial Report: REO-RES Compliance Report Appendix N7: Annual Report: Solar Energy Standard
Docket No. E-002/RP-10-825 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2011-2025 Resource Plan **August 5, 2013 Notice**	Page 2, Para 1	The Commission expects utilities to include in their resource plans filed after August 1, 2013 an explanation how the resource plan helps the utility achieve the greenhouse gas reduction goals, renewable energy standard, and solar energy standard as listed in the above-referenced legislation. Parties should also be prepared to discuss the matter in comments.	Chapter 4: Preferred Plan Appendix H: Environmental Regulations Review Appendix N4: Renewable Energy Compliance Positions Appendix N5: Biennial Report: REO-RES Compliance Report Appendix N7: Annual Report: Solar Energy Standard
Docket No. E-002/RP-10-825 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2011-2025 Resource Plan **August 5, 2013 Notice**	Page 2, Para 2	Utilities should consider adding to their initial resource plan filings the supplemental information listed at page 4 of the Commission's May 10, 2013 Order regarding its completeness review of MP's resource plan in Docket E015/RP-13-53.	See below:

Statute, Rule or Order	Subdivision or Order Point	Information Required by Statute	(7/1/2019) 2020-2034 IRP Location of Required Content

Docket No. E002/RP-10-825 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2011-2025 Resource Plan **August 5, 2013 Notice**	Page 2, Para 3	Utilities consider convening a stakeholder meeting prior to filing their initial IRPs to answer questions about assumptions used in the filing, for the purpose of responding to questions which could enhance parties' understanding of the filing and reducing the number of information requests parties may need to file.	Appendix O1: Summary of IRP Stakeholder Engagement
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 11, 2017 Order**	Order Point 4a	4. Xcel's resource plan is modified as follows: a. to remove 400 MW of large-scale solar in 2016–2021. Xcel shall acquire approximately 650 MW of solar in 2016–2021 through a combination of the Company's community solar gardens program or other acquisitions. The Company may pursue additional, cost-effective solar resources if it is in the best interests of its customers.	Chapter 3: Minimum System Needs Appendix N8: Monthly Report: Solar Gardens June 2019
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 11, 2017 Order**	Order Point 7	7. Xcel's schedule to retire Sherco 2 in 2023, and Sherco 1 in 2026, is approved.	Chapter 4: Preferred Plan
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 11, 2017 Order**	Order Point 8	8. The Commission finds that more likely than not there will be a need for approximately 750 MW of intermediate capacity coinciding with the retirement of Sherco 1 in 2026.	Chapter 4: Preferred Plan
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 11, 2017 Order**	Order Point 10	10. Xcel shall acquire no less than 400 MW of additional demand response by 2023.	Chapter 3: Minimum System Needs Chapter 4: Preferred Plan Chapter 5: Economic Modeling Framework Appendix G1: Demand Side Management

Statute, Rule or Order	Subdivision or Order Point	Information Required by Statute	(7/1/2019) 2020-2034 IRP Location of Required Content
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 11, 2017 Order**	Order Point 12	12. Xcel shall investigate the potential for an energy-efficiency competitive bidding process for customers that have opted out of the statewide Conservation Improvement Program (CIP) under Minn. Stat. § 216B.241, subd. 1a(b).	Appendix G1: Demand Side Management
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 11, 2017 Order**	Order Point 13	13. Xcel shall file its next resource plan on February 1, 2019.	See Docket No. E002/RP-15-21, Minnesota Public Utilities Commission's Order Extending Deadline for Filing Next Resource Plan (January30, 2019)
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 11, 2017 Order**	Order Point 14a	14. In its next resource plan filing, Xcel shall: a. describe its plans and possible scenarios for cost-effective and orderly retirement of its aging baseload fleet, including Sherco, King, Monticello, and Prairie Island.	Appendix J1: Baseload Study
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 11, 2017 Order**	Order Point 14b	b. evaluate combinations of supply-side (distributed and centralized), demand-side, and transmission solutions that could in the aggregate meet post-retirement energy and capacity needs as well as contribute to grid support.	Chapter 5: Economic Modeling Framework Appendix L: Sherco CC Appendix I: Supporting Infrastructure: Transmission & Distribution Appendix J1: Baseload Study
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 11, 2017 Order**	Order Point 14c	c. explore the role of cost-effective combined heat and power solutions.	Appendix S: Combined Heat and Power Study (EPRI) Appendix F6: Resource Options
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 11, 2017 Order**	Order Point 14d	d. report on its solar acquisition progress.	Chapter 3: Minimum System Needs Appendix N8: Monthly Report: Solar Gardens June 2019
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 11, 2017 Order**	Order Point 14e	e. provide a full and thorough cost-effectiveness study that takes into account the technical and economic achievability of 1,000 MW of additional demand response, or approximately 20% of Xcel's system peak in total by 2025.	Appendix G1: Demand Side Management Appendix G3: DR Cost Effectiveness at NSP (Brattle)
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 11, 2017 Order**	Order Point 14f	f. summarize its investigation and findings concerning the potential for an energy-efficiency competitive bidding process for customers that have opted out of CIP.	Appendix G1: Demand Side Management
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 11, 2017 Order**	Order Point 15	15. In future resource plan filings, analysis and inputs must, to the extent possible, be consistent with Xcel's distribution system planning.	Chapter 5: Economic Modeling Framework Appendix F1: Load & DER Forecasting
Docket No. E999/CI-07-1199 & E999/DI-17-53 In the Matter of Establishing an Estimate of the Costs of Future Carbon Dioxide Regulation on Electricity Generation Under Minnesota Statutes § 216H.06 & In the Matter of Establishing an Updated 2016 Estimate of the Costs of Future Carbon Dioxide Regulation on Electricity Generation Under Minn. Stat. § 216H.06 **June 11, 2018 Order**	Order Point 1	1. The Commission hereby quantifies and establishes the range of regulatory costs of carbon dioxide emissions as $5 to $25 per short ton effective 2025 and thereafter.	Chapter 5: Economic Modeling Framework Appendix F2: Strategist Modeling Assumptions & Inputs

Stat. § 216H.06 **June 11, 2018 Order**	Order Point 2B	B. Incorporate, for all years, the high end of the range of environmental costs for CO2 as approved by the Commission in its January 3, 2018 order.	Chapter 5: Economic Modeling Framework Appendix F2: Strategist Modeling Assumptions & Inputs
Docket No. E999/CI-07-1199 & E999/DI-17-53 In the Matter of Establishing an Estimate of the Costs of Future Carbon Dioxide Regulation on Electricity Generation Under Minnesota Statutes § 216H.06 & In the Matter of Establishing an Updated 2016 Estimate of the Costs of Future Carbon Dioxide Regulation on Electricity Generation Under Minn. Stat. § 216H.06 **June 11, 2018 Order**	Order Point 2C	C. Incorporate the low end of the range of environmental costs for CO2 but substituting, for planning years after 2024, the low end of the range of regulatory costs for CO2 regulations, in lieu of environmental costs.	Chapter 5: Economic Modeling Framework Appendix F2: Strategist Modeling Assumptions & Inputs
Docket No. E999/CI-07-1199 & E999/DI-17-53 In the Matter of Establishing an Estimate of the Costs of Future Carbon Dioxide Regulation on Electricity Generation Under Minnesota Statutes § 216H.06 & In the Matter of Establishing an Updated 2016 Estimate of the Costs of Future Carbon Dioxide Regulation on Electricity Generation Under Minn. Stat. § 216H.06 **June 11, 2018 Order**	Order Point 2D	D. Incorporate the high end of the range of environmental costs for CO2 but substituting, for planning years after 2024, the high end of the range of regulatory costs for CO2 regulations, in lieu of environmental costs.	Chapter 5: Economic Modeling Framework Appendix F2: Strategist Modeling Assumptions & Inputs
Docket No. E999/CI-07-1199 & E999/DI-17-53 In the Matter of Establishing an Estimate of the Costs of Future Carbon Dioxide Regulation on Electricity Generation Under Minnesota Statutes § 216H.06 & In the Matter of Establishing an Updated 2016 Estimate of the Costs of Future Carbon Dioxide Regulation on Electricity Generation Under Minn. Stat. § 216H.06 **June 11, 2018 Order**	Order Point 2	Consistent with the Commission decision in the Order Updating Environmental Costs, utilities shall include at least one scenario that excludes consideration of CO2 costs.	Chapter 5: Economic Modeling Framework Appendix F2: Strategist Modeling Assumptions & Inputs
E999/CI-14-643 In the Matter of the Further Investigation into Environmental and Socioeconomic Costs Under Minnesota Statutes Section 216B.2422, Subdivision 3 **1/3/2018 Order**	Order Point 1	1. The Commission hereby quantifies and establishes the range of environmental cost of carbon dioxide emissions associated with electricity generation as follows: •The low end of the range shall reflect the global damage of the last (marginal) short ton emitted, calculated through the year 2100, with a 5.0% discount rate. •The high end of the range shall reflect the global damage of the last (marginal) short ton emitted, calculated through the year 2300, with a 3.0% discount rate.	Chapter 5: Economic Modeling Framework Appendix F2: Strategist Modeling Assumptions & Inputs
E999/CI-14-643 In the Matter of the Further Investigation into Environmental and Socioeconomic Costs Under Minnesota Statutes Section 216B.2422, Subdivision 3 **1/3/2018 Order**	Order Point 3	3. In resource-selection proceedings, utilities shall continue to analyze potential resources under a range of assumptions about environmental values—including at least one scenario that excludes consideration of environmental externalities.	Appendix F3: Scenario Sensitivity Analysis: PVRR and PVSC Summary
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 30, 2019 Order**	Order Point 1	1. Xcel's next resource plan shall be filed by July 1, 2019.	This filing has been made July 1, 2019 in Docket No. E002/RP-19-368

Statute, Rule or Order	Subdivision or Order Point	Information Required by Statute	(7/1/2019) 2020-2034 IRP Location of Required Content
Docket No. E002/RP-15-21 In the Matter of Northern States Power Company d/b/a/Xcel Energy's Application for Approval of its 2016-2030 Resource Plan **January 30, 2019 Order**	Order Point 2	2. Xcel shall submit the files necessary to recreate the Company's 2020–2034 Reference Case, as summarized at Xcel's October 23, 2018 IRP Workshop, and shall provide the Strategist files with the same assumptions as in the Company's 2020–2034 Reference Case but using the midpoint of the Commission's most recently approved externalities and regulatory costs of carbon.	DOC IR No. 1 Docket No. IP6949, E002/PA-18-702 - submitted on November 27, 2019. See Compliance Filing submitted on May 30, 2019 in Docket No. E002/RP-19-368 regarding this Order Requirement for additional information.

APPENDIX B – ACRONYMS & TERMS

ACRONYM / TERM	DEFINITION
AC	Alternating Current
ACE	Affordable Clean Energy rule
ACI	Activated Carbon Injection
ADMS	Advanced Distribution Management System
AEO	Annual Energy Outlook
AFC	Accelerated Fleet Change
ALJ	Administrative Law Judge
AMI	Advanced Metering Infrastructure
ASHP	Air-Source Heat Pumps
AWEA	American Wind Energy Association
BA	Balancing Authority
BACT	Best Available Control Technology
BART	Best Available Retrofit Technology
BO	Buildout Scenario
BSER	Best System of Emission Reduction
C&I	Commercial and Industrial (Customers)
CAA	Clean Air Act
CAGR	Compound Annual Growth Rate
CAIDI	Net capacity factor of power plant, typically expressed as percentage, is ratio of its actual output over period of time to its potential output if it were possible for it to operate at full nameplate capacity indefinitely.
CAIR	Clean Air Interstate Rule
CAP	Competitive Acquisition Process
Capacity Factor	Measure of how often an electric generator runs for a specific period of time. Indicates how much electricity a generator actually produces relative to the maximum it could produce at continuous full power operation during the same period.
CapX2020	Coordinated transmission development effort by group of 11 regional utilities (the CapX2020 Utilities) in MN, ND, SD and WI.
C-BED	Community-Based Energy Development
CBECS	Commercial Buildings Energy Consumption Survey
CC	Combined Cycle
CCGT	Combined Cycle Gas Turbine
CCOSS	Class Cost of Service Stufy
CCRs	Coal Combustion Residuals (often referred to as coal ash)
CCS	Carbon Capture and Sequestration
CEE	Center for Energy and Environment
CEL	Capacity Export Limit
CER	Capital Project Module
CERA	Cambridge Energy Research Associates

ACRONYM / TERM	DEFINITION
CFC	Continued Fleet Change
CH_4	Methane
CHP	Combined Heat and Power
CIL	Capacity Import Limit
CIP	Conservation Improvement Program
Circuit Breaker	An electromechanical device used to configure the flow of electricity on the distribution grid. A circuit breaker is designed to open or close while electricity is flowing through the circuit. When a circuit breaker is open, no electricity is flowing through the circuit.
CO	Carbon Monoxide
CO_2	Carbon Dioxide
CO_{2e}	Carbon Dioxide Equivalents
CON	Certificate of Need
CONE	Cost of New Entry
CPD	Coincident Peak Demand
CPNode	Commercial Pricing Mode
CRP	Certified Renewable Percentage
CSAPR	Cross-State Air Pollution Rule
CSG	Community Solar Garden
CT	Combustion Turbine
CWA	Clean Water Act
CWIP	Construction Work in Progress
DA	Day Ahead
DEM	Drive Electric Minnesota
DER	Distributed Energy Resources
DG	Distributed Generation
DIR	Dispatch Intermittent Resource Protocol
DNR	Department of Natural Resources
DOC	Department of Commerce
DOE	U.S. Department of Energy
DOI	Department of the Interior
DPP	Definitive Planning Process
DR	Demand Response
DSD	Minnesota Deemed Savings Database
DSM	Demand Side Management
E3	Energy and Environmental Economics, Inc.
ECC	Economic Carrying Charge
EE	Energy Efficiency
eGRID	Emissions and Generation Resource Integrated Database
EGU	Electric Generating Unit
EIA	Energy Information Administration
ELCC	Effective Load Carrying Capability
ELGs	Effluent Limitation Guidelines
EPA	Environmental Protection Agency

ACRONYM / TERM	DEFINITION
EPA Clean Air Act 111d Rule	Draft regulation to reduce carbon dioxide gas emissions from existing power plants that burn coal and other fossil fuels.
EPRI	Electric Power Research Institute
EQB	Environmental Quality Board
ESA	Endangered Species Act
EVs	Electric Vehicles
Externality Values	Range of environmental costs.
FAN	Field Area Networks
Fault	Abnormal condition on electric system, such as short circuit, broken wire or intermittent connection.
Feeder	Lines connecting distribution substations to taps.
FERC	Federal Energy Regulatory Commission
FERC Order 1000	Rule mandating how public utility transmission providers plan for and allocate costs of new projects on regional and interregional basis.
FIPs	Federal Implementation Plans
FL&U	Fuel Lost and Unaccounted
FLISR	Fault Location, Isolation, and Service Restoration
FWS	U.S. Fish and Wildlife Service
Gas Burn	Energy from New Natural Gas Generation
GAF	Generation Module
GHG	Greenhouse Gas
GW	Gigawatt
GWh	Gigawatt Hour
GWP	Global Warming Potential
HDVs	Heavy-Duty Vehicles
HVAC	High-Voltage Alternating Current
HVDC	High-Voltage Direct Current
IB MACT	Hazardous Air Pollutants from Industrial Boilers
IBEW	International Brotherhood of Electrical Workers
ICAP	Installed Capacity Value
ICE	Internal Combustion Engine
IDP	Integrated Distribution Plan
IDS	Interdepartmental Sales
IGCC	Integrated Gasification Combined Cycle
INPO	Institute of Nuclear Power Operations
IPCC	Intergovernmental Panel on Climate Change
IPPs	Independent Power Producers
IRP	Integrated Resource Plan
ITC	Investment Tax Credit
ISOs	Independent System Operators
JCOSS	Jurisdictional Cost of Service Study
kV	Kilovolt

ACRONYM / TERM	DEFINITION
kVA	Kilovolt Amps: 1,000 Volt-Amps. Volt is measure of force of electricity. Amp (Ampere) is measure of flow of electricity.
kWh	Kilowatt
LAF	Load Module
LBA	Load Balancing Authorities
LCM	Life Cycle Management
LCOE	Levelized Cost of Energy
LCOS	Levelized Cost of Storage
LCR	Local Clearing Requirement
LDVx	Light-Duty Vehicles
LEAP	Long-range Energy Alternatives Planning
LED	Solid State Lighting
LFC	Limited Fleet Change
LMF	Load Management Forecast
LMPs	Locational Marginal Prices
LOLE	Loss of Load Expectation
LOLP	Loss of Load Probability
LRR	Local Reliability Requirement
LRZ	Local Resource Zone
LSE	Load Serving Entities
LTRA	Long Term Reliability Assessment
MATS	National Emission Standards for Hazardous Air Pollutants for Coal- and Oil-Fired Power Plants. This rule is often referred to as the Mercury and Air Toxics Standard.
MDVs	Medium-Duty Vehicles
MEC	Mankato Energy Center
MEFF	Minnesota Energy Future Framework
MGP	Manufactured Gas Plants
MISO	Midcontinent Independent System Operator, Inc.: Non-profit organization providing reliable coordination and regional planning services including: regional planning, generation interconnection, maintenance coordination, market monitoring and dispute resolution.
MMBTU	Million British Thermal Units
MMERA	Minnesota Mercury Emissions Reduction Act
MPCA	Minnesota Pollution Control Agency
MPUC	Minnesota Public Utilities Commission
M-RETS	Midwest Renewable Energy Tracking System
MTEP	MISO Transmission Expansion Plan
MW	Megawatt
MWh	Megawatt Hour
MVA	Mega Volt Amps: 1,000,000 amps or 1,000 kVA

ACRONYM / TERM	DEFINITION
MVP	Multi Value Project: Regional transmission solutions that meet one or more of three goals: reliably and economically enable regional public policy needs, provide multiple types of regional economic value, and provide a combination of regional reliability and economic value.
N_2O	Nitrous Oxide
NAAQS	National Ambient Air Quality Standards
NDPSC	North Dakota Public Service Commission
NEEP	Northeast Energy Efficiency Partnerships
NERC	North American Electric Reliability Corporation
NGEA	Minnesota's Next Generation Energy Act
NMFS	National Marine Fisheries Service
NO_2	Nitrogen Dioxide
NO_x	Nitrogen Oxide
NOAA	National Oceanic and Atmospheric Administration
NPDES	National Pollutant Discharge Elimination System
NPV	Net Present Value
NRC	Nuclear Regulatory Commission
NREL	National Renewable Energy Laboratory
NSPM	Northern States Power Company-Minnesota
NSPW	Northern States Power Company-Wisconsin
NSPS	New Source Performance Standards
NSR	New Source Review Section of the Clean Air Act
O&M	Operating and Maintenance
O_3	Ozone
OFA	Over-Fire Air
OSPA	Sales to Public Authorities
Pb	Lead
PCBs	Polychlorinated Biphenyls
PCOR	U.S. Department of Energy's Plains Carbon Dioxide Reduction Partnership
PI	Prairie Island
PIRA	Petroleum Industry Research Associates
Plume Blight	Smoke, dust, colored gas plumes, or layered haze emitted from stacks which obscure the sky or horizon and are relatable to a single source or small group of sources.
PM	Particulate Matter
$PM_{2.5}$	Fine Particulate Matter under 2.5 micrometers
PM_{10}	Coarse Particulate Matter under 10 micrometers
PPA	Power Purchase Agreement
PPB	Parts Per Billion
PPM	Parts Per Million

ACRONYM / TERM	DEFINITION
PRC	Planning Resource Credits
PRPs	Potentially Responsible Parties
PRM	Planning Reserve Margin
PRMR	Planning Reserve Margin Requirement
Proview	Expansion Planning Module
PSD	Prevention of Significant Deterioration Section of the Clean Air Act
PSHL	Public Street and Highway Lighting
PTC	Production Tax Credit
PV	Photovoltaic
PVRR	Present Value Revenue Requirement
PVSC	Present Value of Societal Costs
RA	Resource Adequacy
RAC	Reliability Assessment Commitment
RAVI	Reasonably Attributable Visibility Impairment
RCRA	Resource Conservation and Recovery Act
RDF	Refuse Derived Fuel or Renewable Development Fund
Recloser	Circuit breaker that includes mechanism to automatically close (reconnect) after set period of time. Reclosers are used to restore service after momentary fault.
RECAP	E3's Renewable Energy Capacity model
RECs	Renewable Energy Credits: A certificate representing all of the environmental attributes of one MWh of generation from a renewable resource.
Reference Case	Baseline scenario identifying necessary resource additions.
REO	Renewable Energy Objective
REPI	Renewable Energy Production Incentive
RES	Renewable Energy Standard
RESOLVE	E3's Renewable Energy Solutions model
Retrofill	Remove contaminated oil and replace with clean oil.
RFP	Request For Proposal
RGGI	United States' Regional Greenhouse Gas Initiative
RHR	Regional Haze Rule
RIIA	Renewable Integration Impact Assessment
RPS	Renewable Portfolio Standard
RSG	Revenue Sufficiency Guarantee (Charges): Direct result of production shortfalls relative to earlier forecasts.
RTF	Resource Treatment Framework
RTO	Regional Transmission Organization
S*R	Solar Rewards (Company's Program)

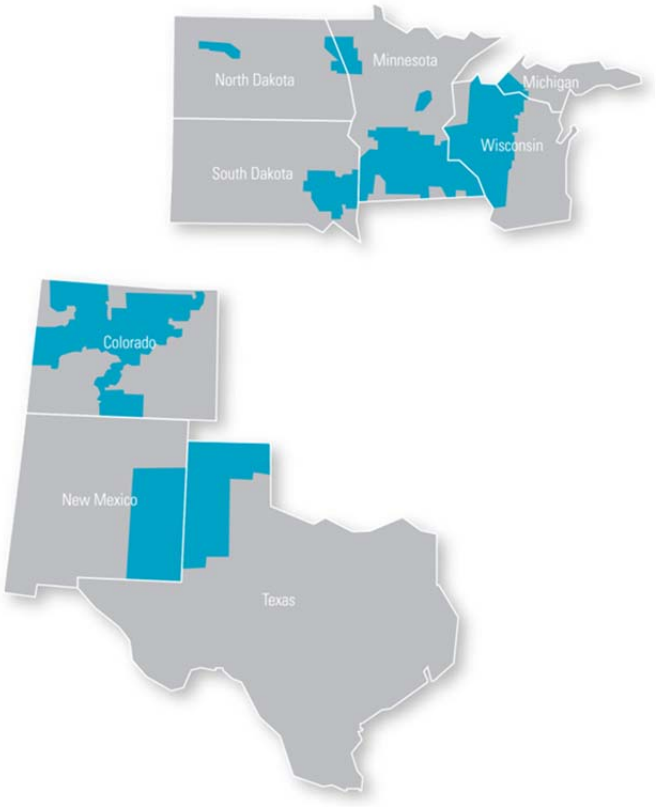
ACRONYM / TERM	DEFINITION
S*RC	Solar Rewards Community (Company's Community Solar Gardens Program)
SAIDI	System Average Interruption Frequency Index: Measures average number of times customer is interrupted over given period (usually monthly or annually). Lower values are better.
SAIFI	System Average Interruption Frequency Index: Measures average number of times customer is interrupted over given period (usually monthly or annually). Lower values are better.
SCADA	Supervisory Control and Data Acquisition
SCC	Social Cost of Carbon
SCR	Selective Catalytic Reduction
SDPUC	South Dakota Public Utilities Commission
SEPA	Solar Electric Power Association
SES	Minnesota Solar Energy Standard: Minn. Stat. § 216B.1691, subd. 2f, which requires 1.5% of retail sales to be sourced from new solar resources. SES is incremental to the Renewable Energy Standard (RES).
SFH	Single Family Housing
SIP	State Implementation Plan
SO_2	Sulfur Dioxide
SO_x	Sulfur Oxide
SolarTAC	Solar Technology Acceleration Center
SPP	Southwest Power Pool
SQ	Status Quo
S-RECs	Solar Renewable Energy Credits: Created from a solar resource installed after August 1, 2013 and eligible to be used for compliance with the MN Solar Energy Standard.
Switch	Electromechanical devise used to configure the flow of electricity on distribution grid. A switch is designed to be opened or closed when electricity is not flowing through circuit. When switch is open, no electricity is flowing through circuit.
Tap	Final leg of distribution system before connecting to customer premises.
THI	Temperature Humidity Index
Transcos	Transmission-only entities designed to respond to the FERC Order 1000.
Transformer	Electromechanical devise that converts alternating current to higher or lower voltage.
Transmission Inadequacies	Identified deficiencies in the transmission system that need to be upgraded to keep the transmission system within its defined limits.
TRC	Total Resource Cost

ACRONYM / TERM	DEFINITION
TSD	Technical Support Document
UCAP	Production Capability Value
USACE	U.S. Army Corps of Engineers
V2G	Vehicle-To-Grid
VAr	Voltage and Reactive Power
VMT	Vehicle Miles Traveled
VOCs	Volatile Organic Compounds
W2B	Wind2Battery Project
WDNR	Wisconsin Department of Natural Resources
WOTUS	Waters of the United States
WTP	Worker Transition Plan
ZRC	Zonal Resource Credit

APPENDIX C – ABOUT XCEL ENERGY

Xcel Energy is a major U.S. electric and natural gas company based in Minneapolis, Minnesota. We have regulated operations in eight Midwestern and Western states - Colorado, Michigan, Minnesota, New Mexico, North Dakota, South Dakota, Texas and Wisconsin – where we provide a comprehensive portfolio of energy-related products and services to approximately 3.6 million electricity customers and 2 million natural gas customers. Our Upper Midwest service area is part of an integrated system of generation and transmission made up of two operating companies – Northern States Power Company-Minnesota (NSPM), which serves North Dakota and South Dakota in addition to Minnesota; and Northern States Power Company-Wisconsin (NSPW), which serves Wisconsin and Michigan – collectively referred to as the NSP system. Xcel Energy serves over 1.8 million customers in its NSP service territories. Figure 1 below illustrates Xcel Energy's nationwide territory.

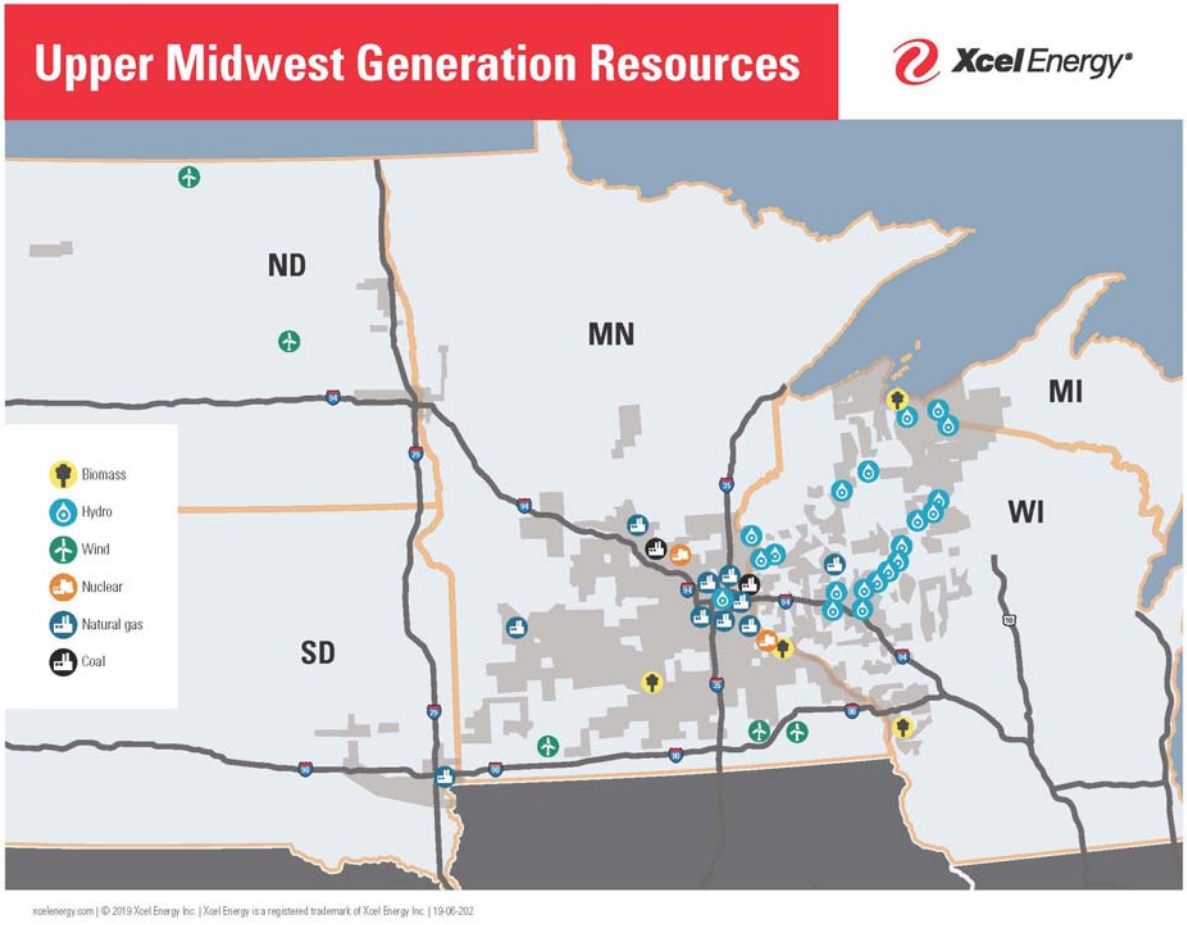
Figure 1: Xcel Energy Territory



Approximately 88 percent of our NSP customers are residential, with commercial and industrial customers comprising most of the remaining 12 percent. The distribution of electricity sales by type of customer, however, is significantly different. Residential

customers make up approximately 29 percent of electricity sales, with commercial and industrial customers making up most of the remaining 71 percent.

Figure 2: NSP System Generation Resources



NSP operates a diverse electric generating fleet, which includes facilities that use several different types of fuel: coal, natural gas, nuclear, wind, hydro, and biomass. This fleet of generating resources is illustrated by the map in Figure 2 above. The diversity of this fleet provides customers with a variety of generation options and protects them from the excessive risk of reliance on any one type of resource. Our overall strategy for purchasing our diverse generating fuels focuses on three objectives: competitive cost, diversity and reliability. Our fleet includes power plants with a net maximum capacity of over 9,500 MW, more than 8,400 miles of transmission lines, and approximately 550 transmission and distribution substations. We also have over 3,700 MW of Purchase Power Agreements (PPAs) for renewable and natural gas resources, including over 200 MW of large-scale solar and an additional expected 600 MW of Community Solar Gardens online by 2020.

Xcel Energy has long been a leader in delivering clean energy while maintaining outstanding reliability and affordability. Back in 2005, we were the leading utility wind energy provider in the country, despite the fact that wind comprised only 3 percent of our generation. By 2027, we expect renewable energy — the vast majority being wind — will account for 48 percent of our mix and will be our largest source of energy for our customers.

Along the way, we have made steady progress reducing carbon dioxide by transitioning away from fossil fuels, incorporating renewables and developing award-winning energy efficiency programs. Our 2018 carbon emissions were approximately 40 percent lower than our 2005 baseline. That progress put us on pace to hit our previous goal of reducing carbon 60 percent across all eight states in which we do business by 2030.

But a confluence of market forces — improving technology, falling prices and the risk of climate change — convinced us that we can do more, sooner. That is why in December, we became the first electric utility in the country to announce our aspiration to produce 100-percent carbon-free electricity for customers by 2050. At the same time, we announced a new interim target of reducing carbon dioxide emissions 80 percent by 2030.

Setting our sights on this ambitious vision allows us to drive the conversation rather than react to it. It also gives us time for the development of technologies not currently available that will be critical for achieving 100 percent carbon-free electricity. We are excited to make advances towards this vision and build the future together.

APPENDIX D – NON-TECHNICAL SUMMARY

I. INTRODUCTION

Northern States Power Company-Minnesota is a wholly-owned operating subsidiary of Xcel Energy, Inc. that owns and operates, in conjunction with its affiliate Northern States Power Company-Wisconsin, the integrated NSP System of generation and transmission assets that serves more than 1.8 million electric customers in Michigan, Minnesota, North Dakota, South Dakota, and Wisconsin. This 2020-2034 Upper Midwest Integrated Resource Plan builds on our strong foundation of cost-effective environmental performance and the generating fleet transition we began in our last Resource Plan.

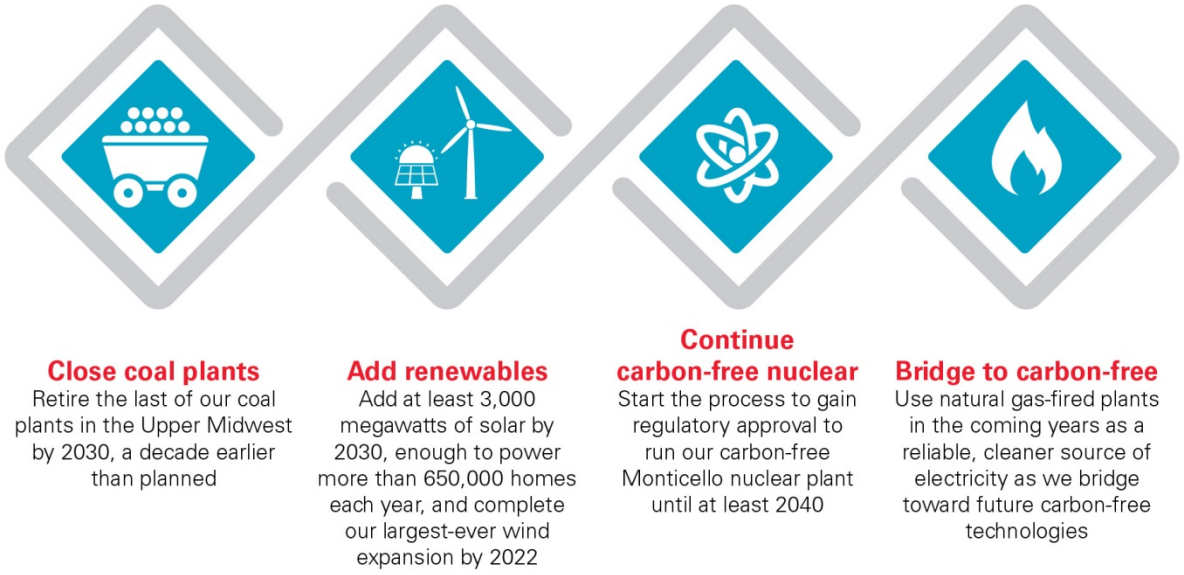
Our Resource Plan is founded on unprecedented levels of stakeholder engagement and technical analyses that examined an orderly retirement of our baseload generating units. We engaged a national expert on energy policy and economics, Dr. Susan Tierney with Analysis Group. Dr. Tierney not only brought a national perspective, but was also an independent third party that helped facilitate engaging and productive dialogue with stakeholders. We also retained Energy and Environmental Economics, Inc. (E3), to perform independent modeling and analysis of our system in order to ensure transparent work and access to the data and models for stakeholders. E3 is a recognized industry-leading firm based in San Francisco and consults extensively with utilities, developers, government agencies, and environmental groups on clean energy issues.

To develop our plan, we analyzed numerous assumptions and sensitivities to identify the plan that best meets customer needs, achieves our obligations and goals, and ensures we maintain a resilient and reliable grid. Our Preferred Plan represents the set of generation and conservation resources that we propose to meet our customers' needs over the next 15 years, which we believe is the best suite of resources that meets our planning objectives.

Figure 1: Xcel Energy Integrated Resource Plan Objectives

Our Preferred Plan includes the elimination of coal-fired generation from our system by 2030, the acquisition of at least 3,000 megawatts (MW) of utility-scale solar, a substantial increase in energy efficiency (EE) programs and Demand Response (DR), an operating extension of our carbon-free Monticello nuclear plant, and a proposal to construct a new combined cycle at our Sherco site. In total, we have an ambitious plan that supports the Company's goal of reducing carbon emissions 80 percent by 2030, and it moves us toward our ultimate vision of 100 percent carbon-free energy by 2050.

Figure 2: Preferred Plan Highlights



Our Preferred Plan will be evaluated based on its ability to: maintain or improve the adequacy and reliability of utility service; keep the customers' bills and the utility's rates as low as practicable, given regulatory and other constraints; minimize adverse socioeconomic effects and adverse effects upon the environment; enhance the utility's ability to respond to changes in the financial, social, and technological factors affecting its operations; and limit the risk of adverse effects on the utility and its customers from financial, social, and technological factors that the utility cannot control.[1]

II. A CHANGING PLANNING LANDSCAPE

There are key internal and external market contexts that affect how we have developed, and plan to execute on, our Preferred Plan. Below provide a contextual discussion of the planning landscape within which we developed and are presenting the results of our current resource planning efforts.

A. Regional Reliability and Market Constructs

While the regional system operator that designs many of our market and planning requirements continues to examine the effects of high renewable adoption on the grid, it has not yet developed robust and forward-looking capacity accreditation constructs to account for how renewables' contributions to peak demand will change

[1] Minn. R. 7843.0500, subp. 3

over time. This introduces complexity to designing a plan far into the future, and how we carry out those plans.

Likewise, while we are committed to substantially increasing renewables on our system to achieve our carbon reduction goals, we also anticipate facing challenges to integrating this new clean generation, given the delayed interconnection studies and current limited state of open transmission availability. Our ability to connect these new renewables in a cost-effective manner depends materially on constructs that enable careful management of our interconnection rights in the near-to-medium term as well as new transmission in the long term.

B. Distributed Energy Resources (DER)

At the same time as we work to clean our grid mix, we also recognize that customers are now exercising more choice around how and from where they consume energy. Our customers' adoption of DER and new types of load mean that consumption patterns from our centralized power system are changing. The opportunities are exciting; however, customer adoption of DER and new types of load behind the meter introduces uncertainties in our planning processes – particularly if we do not have adequate visibility into how and when that new DER or demand is coming onto our system.

Fortunately, we have made progress integrating distribution planning into our resource planning. As with other aspects of the industry that are transitioning and advancing, we are on the forefront of integrated distribution planning, and evaluating and procuring the next generation of distribution planning tools. These tools are needed to increase our forecasting and analysis capabilities and impact the integration of planning processes. Thus, while work continues to incorporate these planning processes and DER on our system, additional work and tools are needed.

C. Community and Employee Considerations

As we move forward with our carbon reduction goals, we are cognizant that phasing out some of our legacy generation assets has a significant impact not only on our energy mix, but on the economies of communities where those plants are located and the employees who work in those plants. This is particularly true of our coal facilities, where the plants are prominent places of employment and contributors to the property tax base in the community.

As we continue toward achievement of our aggressive carbon goals, we will continue to make significant clean energy investments in the states we serve. As we do so, we

will look for opportunities to create fair access to clean energy programs, jobs and economic development opportunities. Going forward, we continue to be dedicated to working with employees, communities, and stakeholders to manage community impacts throughout our clean energy transition.

D. Customer Preferences

We are increasingly hearing from our customers that they have a growing interest in increasing their energy management capabilities and desire a more customized energy mix than has been traditionally available. Residential customers tell us that they value choice and clean, affordable, and reliable energy. At the same time, municipalities within our service territory are expressing changing expectations to address their citizens' interests in achieving sustainability goals and engage residents around energy issues.

Our customers also are interested in various types of self-generation. This includes increased small-scale solar penetration through behind the meter installations or community solar gardens. Industrial customers are also interested in exploring the addition of larger scale Combined Heat and Power (CHP) installations at their facilities. The installation of self-generation on our system impacts our resource needs, planning goals, and ultimate resource mix.

We also know that customers are sensitive to rate changes. For example, our large industrial customers are energy-intensive and thus highly-sensitive to energy rates, with less sensitivity to other terms of service. These are key considerations as we plan our resource mix to meet the needs of our customers over the planning period.

E. Supply and Technology Trends

The rapid pace of advancement in energy technologies has impacted and will continue to impact the future of our industry. Emerging technologies related to grid modernization, energy storage, electric vehicles, resource extraction, renewable energy and other alternative fuels and generation methods are enabling a smarter and more resilient energy system.

While this new technology provides opportunities for a modernized energy system, operating that system is a complex matter. We are taking a measured approach to identify new and better ways to provide our customers with high quality service, meet increasing environmental requirements, and implement advancements and standardized processes that enhance the safety of our operations and overall value to customers. Our approach to these emerging technologies is to learn from the current

deployments, both internal to Xcel Energy and within the industry, and implement initiatives at the pace of value to our customers and operations.

F. Five State Integrated System

Our integrated Upper Midwest system provides service on a multi-jurisdictional basis to 1.8 million customers across five states. Through this integration, we have historically leveraged economies of scale to support needed investments. Each resource on the Upper Midwest system – whether generation or transmission – was developed in consideration of the whole system, to take advantage of the economies of scale available through integrated system planning. Indeed, planning for the varied needs of each of these five states was critical to the formation of our Preferred Plan.

G. The Evolving NSP System

This accelerated transition away from coal requires the Company to plan for the retirement of 2,400 MW of coal-fired generation in the next decade, which represents almost one-fourth of the total capacity in our current generation fleet. We will also experience a reduction in energy resources due several purchase power contracts expiring.

At the same time, we are increasing the amount of renewable generation on our system. Yet, these resources cannot alone reliably provide customers the energy they demand every hour of every day, or maintain the stability of the grid. Until such time as new technologies develop to fully transition the grid to carbon-free resources, some level of load-supporting, firm dispatchable resources is necessary for grid resilience and customer reliability. As such, our plan incorporates a Reliability Requirement as a bridge until the current planning processes adapt to recognize the transition that is underway.

Taken together, the impact of these system changes was critical to our resource planning analysis as we evaluated meeting our capacity and energy needs while maintaining reliability, retaining flexibility, and avoiding over-reliance on any one fuel source.

The planning landscape underlying this Resource Plan has greatly informed our planning efforts. We continue to believe that proactive leadership in the face of evolving industry, new and proposed environmental regulation, customer expectations, emerging technologies, and changes to the NSP System will allow us to affirmatively address these trends rather than being shaped by them. These evolving

factors also call for sufficient flexibility that allows us to adjust and react as we gain more clarity on the planning landscape.

III. KEY CONSIDERATIONS OF THE PREFERRED PLAN

Resource Planning is a complex and integrated process of planning for the capacity, energy, and emission requirements of the electric system. The process incorporates a number of key assumptions or industry projections that helps all participants develop a common vision of what the future planning environment may look like. This ongoing planning process requires utilities to examine and establish a long-term proposal for management, operation, and expansion or contraction of their generating and demand management resources to meet customer needs.

Traditionally a primary focus of resource planning has been to identify the least-cost approach to provide reliable service and meet growing demand. While this is still a part of our foundation, this Plan begins to move away from a more concentrated view of traditional thermal generation to incorporating new generation technologies, increasing carbon-free energy, reducing emission profiles, and thereby positioning the NSP System for the future.

The Preferred Plan we present was developed to address the planning landscape in which it was developed and in consideration of our four key planning objectives: (1) Environmental Benefits and Innovation (2) Reliability (3) Cost (4) Risk Mitigation and Flexibility. Underscoring all of these objectives is our commitment to our employees and the communities within which we operate.

A. Environmental and Innovation

Environmental benefits and the technological innovations that will help us achieve them are front and center in this Resource Plan process. We have made a bold commitment to achieve 80 percent carbon reduction from 2005 levels by 2030, and have considered this target a modeling pillar for all of our potential scenarios. Our Preferred Plan achieves this goal in several ways. First, our Preferred Plan eliminates coal from our system by 2030, extends our carbon-free Monticello plant to 2040, adds at least 4,000 MW of new renewable resources, including substantial new solar capacity additions, and maintains the wind levels committed to in our previous Resource Plan by replacing renewables with renewables when they reach the end of their operating lives.

Many of these resource additions are not needed for a number of years. We therefore expect technological advancements and innovations will create opportunities in

future planning and procurement processes if we are able to retain the flexibility we seek with this plan.

B. Reliability

Our responsibility to ensure a reliable electricity supply for our customers is a fundamental underpinning of our Preferred Plan. We therefore developed a Reliability Requirement that establishes a minimum level of firm dispatchable resources that is required to serve our customers' needs in every hour of every day. We developed the Reliability Requirement through analysis of industry trends and careful study of our system's performance and the broader Midcontinent Independent System Operator (MISO) system's performance during both winter and summer days when renewables were unavailable – sometimes for lengthy durations.[2]

This Requirement does not drive any firm dispatchable load supporting resource additions in our Preferred Plan until after 2030. Prior to 2030, our Preferred Plan relies on two primary sources to ensure reliability: (1) combined cycle (CC) generating plants – specifically the Mankato Energy Center (MEC) that we have proposed to acquire, one at our Sherco location near Becker, Minnesota (Sherco CC), and (2) our Monticello and Prairie Island nuclear units. Combined cycle generating units are intermediate natural gas resources that efficiently address reliability challenges associated with the variability of wind and solar and customer needs, because they can vary their output to adapt as demand for electricity changes over the course of the day and year. With respect to nuclear generation, our proposed extension of the Monticello operating license not only represents a carbon-free workhorse of a resource, it also enhances fuel diversity and provides a generation resource that is not subject to seasonal fuel supply limitations.

C. Cost

Along with leading the clean energy transition and enhancing the customer experience, keeping customer costs low is one of Xcel Energy's central, guiding objectives. Since our last Resource Plan, renewable technology costs – and in particular, solar costs – have continued to decline; we expect this trend to continue

[2] MISO is an independent, not-for-profit organization that delivers safe, cost-effective electric power across 15 U.S. states and the Canadian province of Manitoba. The NSP System is part of MISO, which is part of the Eastern Interconnection that connects the generation and transmission assets of the electrical grids from the Rocky Mountains to the East Coast and from Canada to the Gulf of Mexico. This interconnected network of generating resources and transmission infrastructure works together to seamlessly respond and adjust to dynamic and sometimes adverse circumstances to provide an adequate and reliable supply of electricity to customers.

going forward. Taking advantage of technological advancements is one reason that we can deliver a Preferred Plan that achieves deep carbon reductions for a nominal customer cost of just over one (1) percent Compound Annual Growth Rate (CAGR) over the planning period. And over the long run, our Preferred Plan is expected to yield net present value savings – yielding $203 million of benefits on present value revenue requirements (PVRR) basis and $461 million of benefits on a present value societal costs (PVSC) basis.

D. Risk and Flexibility

Finally, we also seek to mitigate customer risk by ensuring fuel diversity, maintaining appropriate capacity length in our portfolio, and maintaining flexibility in our plans. Portfolio fuel diversity is essential to risk mitigation – especially so, as we transition away from coal. Incorporating a mix of nuclear, load management, intermediate and peaking natural gas capacity, and renewables into our long-term plans ensures that our portfolio is adequately diverse – mitigating the risk associated with overdependence on any one fuel source. Further, the proposed resource additions identified in our Preferred Plan result in a capacity position that is between 500-1,000 MW long in any given year. We believe this modest length is prudent, particularly as we propose to substantially increase renewable resources – adding more than 4,000 MW of incremental new renewable capacity, in addition to our already large wind fleet.

Both MISO and independent analyses suggest that capacity accreditation for solar in particular will decline substantially as more capacity is added. We expect MISO will ultimately recognize this conclusion from its ongoing study of issues associated with integration of high levels of renewables in its planning construct.[3] Therefore, what we believe today to be a long capacity position may actually erode over time.

Maintaining a significant amount of flexibility in our future plans is essential to reliably and affordably navigating the transition of our fleet. To that end, we are deferring a decision on pursuing a license extension at the Prairie Island nuclear plant to subsequent resource plans, thereby preserving flexibility to respond to market conditions at that time.

Underscoring all four of our objectives is our commitment to our employees and the communities within which we operate. We do not make plant closure decisions lightly, and we are committed to supporting our employees at the Sherco and King plants as we prepare to retire these facilities. We also know that the Company is a

[3] We discuss MISO's *Renewable Integration Impact Assessment* (RIIA) in more detail in our Baseload Study, provided as Appendix J1.

major presence in terms of employment and local tax revenues in Becker and Oak Park Heights and the surrounding areas. We also have partners at our Sherco site with Liberty Paper and SMMPA (Southern Minnesota Municipal Power Agency). We are currently participating, alongside Minnesota Power, in a Host Community Impact study, to better understand the potential impact of power plant retirements on host communities. We are committed to continue to work with our employees and communities to navigate this transition together.

IV. THE PREFERRED PLAN

To develop the Preferred Plan, we first developed a Reference Case plan that continues the path we set out in our 2015 Resource Plan, with respect to operation of our baseload generating units. This Reference Case provides an opportunity to at least achieve the carbon reduction goals set-out in our previous Resource Plan, while meeting our minimum system needs and compliance obligations. Our Reference Case provides a base line from which we measured the emission reduction benefits, renewable and other energy additions and estimated cost impacts of our Preferred Plan.

A. Determining Customer Needs

Determining our customers' needs for electricity is a key component of any resource plan, and provides the foundation for determining the type and amount of resources that will be needed over the 15 year planning period. To this, we forecast of customers' needs starts in terms of capacity, or peak demand, which informs the total amount of generating capacity (in megawatts, or MW) needed to meet our customers' needs in the highest demand hour (i.e. peak-hour) in each year of the planning period. We also assess the amount of total energy (measured in megawatt hours or MWh) we expect customers to consume in each year of the planning period. Together, the peak demand and total energy needs inform the type of generating resources that will best meet customer needs.

To this, we add a "reserve margin" prescribed by MISO, which is intended to cover potential uncertainties in the availability of resources or level of demand. We then subtract the resources we already have or expect to have, to determine our net surplus or need. We illustrate this concept and discuss each of the components below.

Figure 3: Net Resource Need/Surplus Calculation

Customer Needs Forecast
Plus MISO Reserve Margin
Equals **Total Capacity Obligation**
Minus Demand Response Capability
Minus Generation Capacity (measured by UCAP)
Minus Generation Adjustments
Equals **Net Resource Need/Surplus**

This analysis yields our net generation capacity surplus or deficit over the planning period, shown below:

From this point, the modeling underlying our resource planning identifies the best combination to meet any net resource deficiencies and the resulting energy mix.

[4] In addition to existing and approved resources, those indicated with a * include pending or proposed resources that we have included across all Scenarios, including the Reference Case.
[5] Includes EE savings from historically installed measures, as well as future EE from bundles modeled in this Resource Plan, achieving 2-3% savings levels. Also includes minimal EV and coincidence adjustments.
[6] Unforced Capacity (UCAP) is a measure of resource adequacy value that we use in modeling to ensure we have sufficient resources to cover our full obligation. These values are discounted based on actual or expected average performance, per MISO, relative to the installed capacity values presented in our expansion plans.

B. Reference Case Expansion Plan and Energy Mix

C. Developing the Preferred Plan

We use a modeling tool called Strategist, which allows us to explore how we best meet our customer and policy requirements under a variety of conditions and at a reasonable cost. We work with internal and external subject matter experts to develop starting assumptions that reflect their expert opinion of likely future conditions. We then test the robustness of the plans through sensitivity analyses by individually changing key assumptions and re-running the plans under these changed assumptions.

Beginning with our Reference Case to meet our minimum system needs, we created 15 scenarios. Because one of our requirements with this Plan was to examine a potential schedule for a cost-effective and orderly retirement of baseload generating units not already scheduled to retire early (King, Sherco 3, Monticello, and Prairie Island Units 1 and 2), we performed technical studies as part of an overall Baseload Study that informed these scenarios and their costs.

These scenarios examined different combinations and timing of baseload unit retirements, and the resulting size, type, and timing of new resources we would need to add in order to continue meeting customers' needs, achieve our 2030 carbon reduction goals, and maintain affordable rates. Key scenario groupings analyzed include:

- *Early Coal.* Analyses to evaluate the economics (i.e. revenue requirement impacts) of retiring King and/or Sherco 3 early.
- *Early Nuclear.* Analyses to test the economics of retiring Monticello and/or Prairie Island early, either alone or together and with the combination of early coal retirements.

- *Extend Nuclear.* Analyses to test the economics of re-licensing Monticello and/or Prairie Island and extending the operational life by ten years over the current retirement date.

Based on these analyses, we believe that our Preferred Plan meets all of our key planning objectives, positions us well to meet customers' needs, reasonably balances outcomes and costs – all while providing us with the necessary strategic flexibility to address the planning landscape.

D. Preferred Plan

Key components of our Preferred Plan include:

- ***Coal Resources*** – Retire our last two units early: King in 2028 (nine years early) and Sherco 3 in 2030 (ten years early). Additionally, continue our plan to retire Sherco 1 and 2 in 2026 and 2023, respectively, and commit to offering Sherco Unit 2 into MISO on a seasonal basis until its retirement.
- ***Nuclear Resources*** – Operate our Monticello unit through 2040 (10 years longer than its current license) and operate both Prairie Island units through the end of their current licenses (PI Unit 1 to 2033 and PI Unit 2 to 2034).[7]
- ***Renewable Resources*** – While the exact wind and solar mix could vary based on a variety of reasons, at this time we propose to add 4,000 MW of cumulative utility scale resources by 2034 (the first being in 2025) and approximately 1,200 MW of cumulative wind by 2034 to replace wind that is set to retire from our system during that period.
- ***Combined Cycle Resources*** – Acquire and operate MEC and build, own and operate Sherco CC to satisfy significant capacity and operational needs created by coal closures.
- ***Firm Load Supporting Resources*** – Starting in 2031, add approximately 1,700 MW of cumulative firm dispatchable, load-supporting resources by 2034.
- ***Demand Side Management*** – Include energy efficiency (EE) programs representing an approximately 780 GWh of savings annually through 2034 (compared to average annual energy savings of 444 GWh in our last Resource Plan) and the addition of 400 MW of incremental Demand Response (DR) by 2023, achieving a total of over 1,500 MW DR by 2034.

[7] Given that our operating licenses for Prairie Island run until 2033 and 2034, we believe there is sufficient time to address the future of that plant in upcoming resource plans.

Table 3 below outlines the proposed timing, type, and size of resource additions comprising our Preferred Plan.

Table 3: Preferred Plan Resource Additions (MW)

	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034

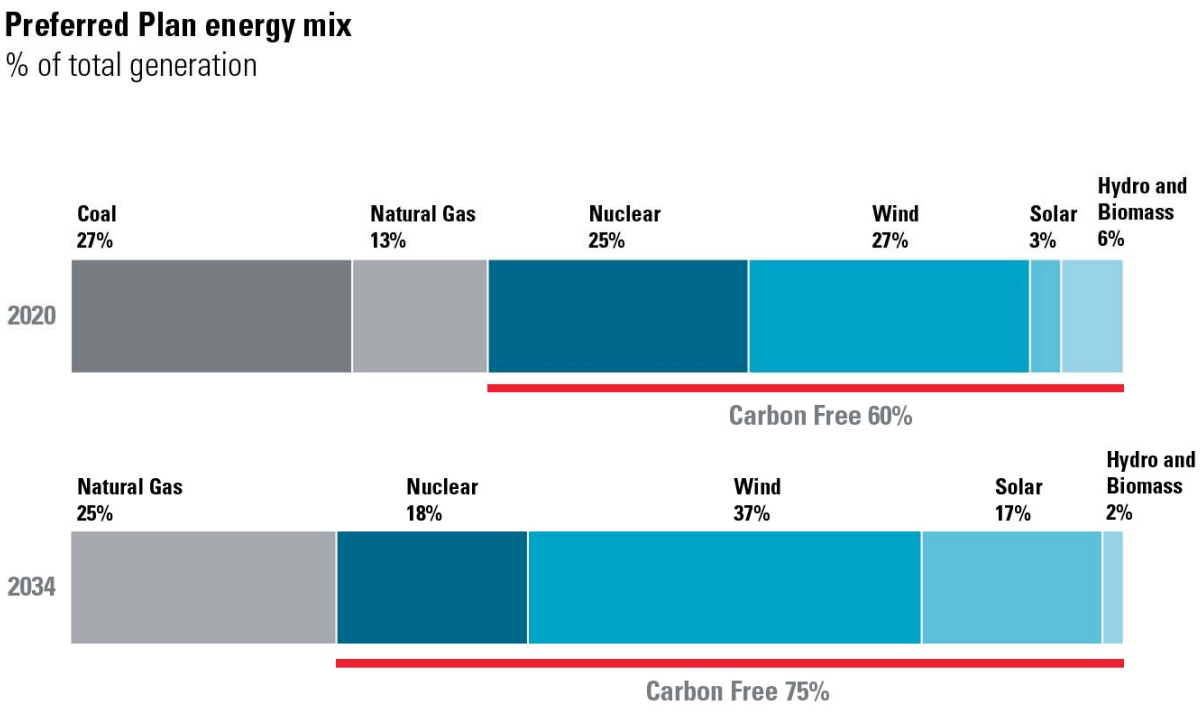
Total	**540**	**172**	**159**	**290**	**226**	**777**	**752**	**2,098**	**700**	**784**	**693**	**838**	**700**	**1,065**	**997**

Our Preferred Plan outlined above would result in the energy mix shown in Figure 4 below.

Figure 4: Preferred Plan Energy Mix



Our Preferred Plan achieves several important goals:

Reliability. Our Preferred Plan maintains the safe and reliable service we have been providing for many years, and ensures that the NSP System has sufficient capacity and energy available during the planning period.

Environmental Outcomes. Implementing our Preferred Plan will allow us to reduce our carbon emissions over 80 percent from 2005 levels by 2030. Additionally, our Preferred Plan adds significant renewable energy to the NSP System.

Strategic Flexibility. Our Preferred Plan positions the Company well in the current planning landscape – meeting near-term needs and creating flexibility for the future. As we have described, planning constructs, policies, and technology costs are all creating uncertainty, which leads us to prioritize strategic flexibility in our plans to preserve the most value for our customers

Affordability. As discussed below in the Rate Impact section, we estimate that our Preferred Plan can be implemented at reasonable cost to our customers.

V. FIVE-YEAR ACTION PLAN

Our Preferred Plan does not identify any incremental capacity needs through 2024. Thus, our actions in the next five years primarily address previously approved or pending resource additions and retirements, wind repowering and procurement to meet specific customer needs, and continuing to achieve reductions in energy demand and load through ambitious DSM programs. We also plan to make targeted investments in supporting infrastructure to accommodate increased renewable energy and DER on the grid, and to gain operational experience with technologies that may play a larger role on our grid in the future. Key highlights are as follows:

Wind. We expect that the 1,850 MW of wind generation resulting from our recent acquisitions and RFPs will achieve commercial operation by 2022. We expect to replace wind capacity that will expire, and we are committed to pursuing repowering and/or contract extension opportunities for this capacity, as part of our "no going back" renewables strategy. Further, we intend to pursue incremental renewable resources as needed to meet customer needs in growing customer programs like Renewable*Connect.

Solar. Our Preferred Plan includes significant amounts of large scale solar, with the initial addition of 500 MW occurring in 2025 – just outside of the five-year Action Plan window. We expect to implement a competitive acquisition process in the 2023 to 2024 timeframe and bring these resources online by the end of 2025. On the distributed solar side, we have included forecasted growth in our plan. If actual distributed solar capacity additions exceed our expectations, we anticipate this will displace a portion of our proposed utility-scale solar resources.

Nuclear. Our Preferred Plan includes a request to operate our Monticello nuclear unit for an additional 10 years beyond its current license. While the license does not end until 2030, we expect to begin a proceeding with the Commission within the next five years and also begin working toward license extension with the Nuclear Regulatory Commission during this timeframe.

Natural Gas/Oil Peaking. We anticipate extending the life of Blue Lake Units 1-4 through 2020-2023,[8] which provides 153 MW of peaking capacity to the NSP System. Our Preferred Plan further includes our acquisition of MEC, which is currently pending Commission consideration. Finally, we plan to continue development activities associated with the Sherco CC during the next five years.

In addition, as discussed in our last Resource Plan, system retirements will impact our current blackstart plans and we are currently analyzing our blackstart path to determine the best fit for our system needs. While we do not propose any action related to the system blackstart at this time, we anticipate addressing this in our next Resource Plan or earlier, if system needs dictate the need to do so.
Coal. As approved in our last Resource Plan, we will take action with MISO and retire Sherco Unit 2 in 2023, and intend to offer it into MISO on a seasonal basis until that time. Though outside the five-year action window, we are proposing to retire the remainder of our coal units (Sherco 2, Sherco 3 and King) before 2030. As with our previous plant retirements, we plan to begin working with our employees and host communities to prepare for this transition.

Demand Response. Our Preferred Plan proposes to acquire 400 MW of DR resources by 2023.

Supporting Infrastructure. Aside from the grid-scale and DER additions included in our Plan, sufficient supporting infrastructure is essential to facilitate our fleet transformation, ensure grid resilience and reliability, and to enable greater DER and DR resources on our system. We expect further and substantial transmission infrastructure development will be necessary over the long-term, which will involve planning in the near-term. We also are continuing to refine our advanced grid strategy and intend to propose implementation of foundational grid modernization investments – and continue our work to integrate planning processes at all levels of the grid.

Resource treatment across states. We continue to explore options with the North Dakota

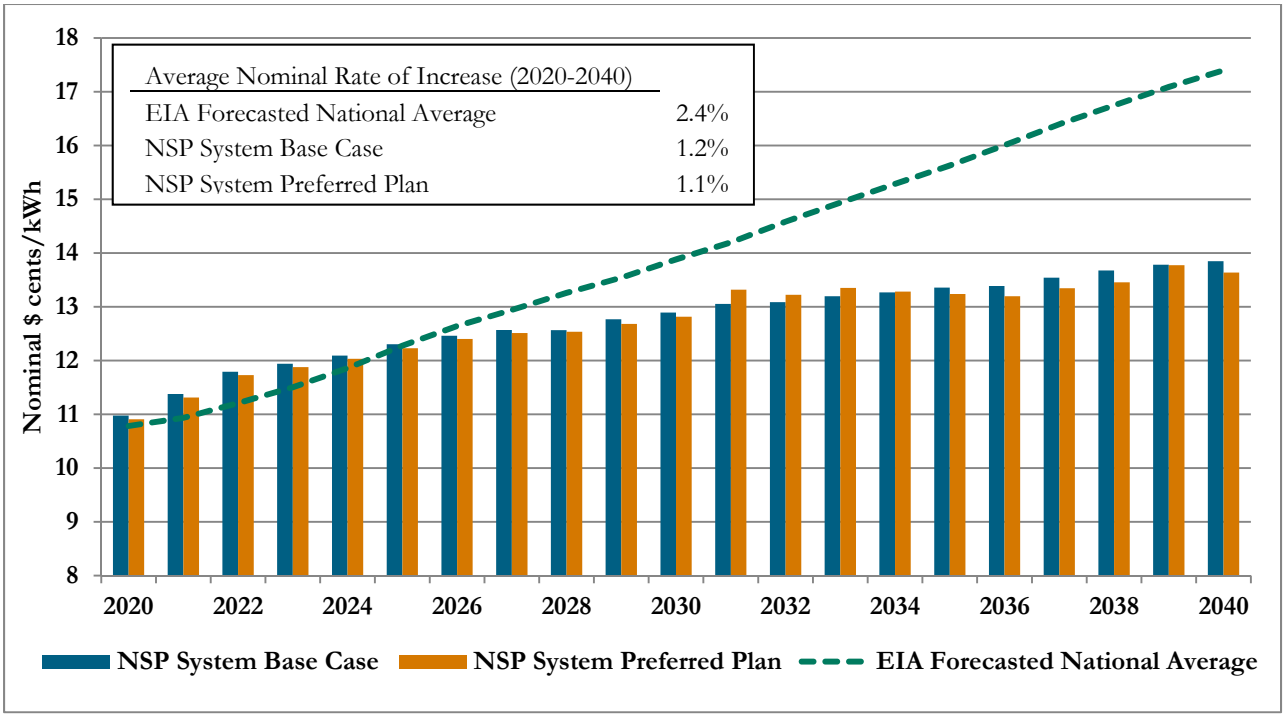
[8] Pending decision in Docket E,G002/D-19-161

Public Service Commission to create a resource planning process can more formally accommodate generation portfolio preferences. We believe additional discussions with all of our state Commissions will be necessary during the five-year action planning period to address differing energy policies and changes in cost allocations that may result.

VI. RATE IMPACTS

Overall, our Preferred Plan results in an estimated average annual increase in revenue requirements less than the Reference Case and just over 1 percent overall. In other words, we can achieve significant CO_2 emissions reductions, with cost impacts that are roughly half the expected national average increase in electricity prices. This is demonstrated in Figure 5 below.

Figure 5: Preferred Plan Average Nominal Cost Comparison
NSP System

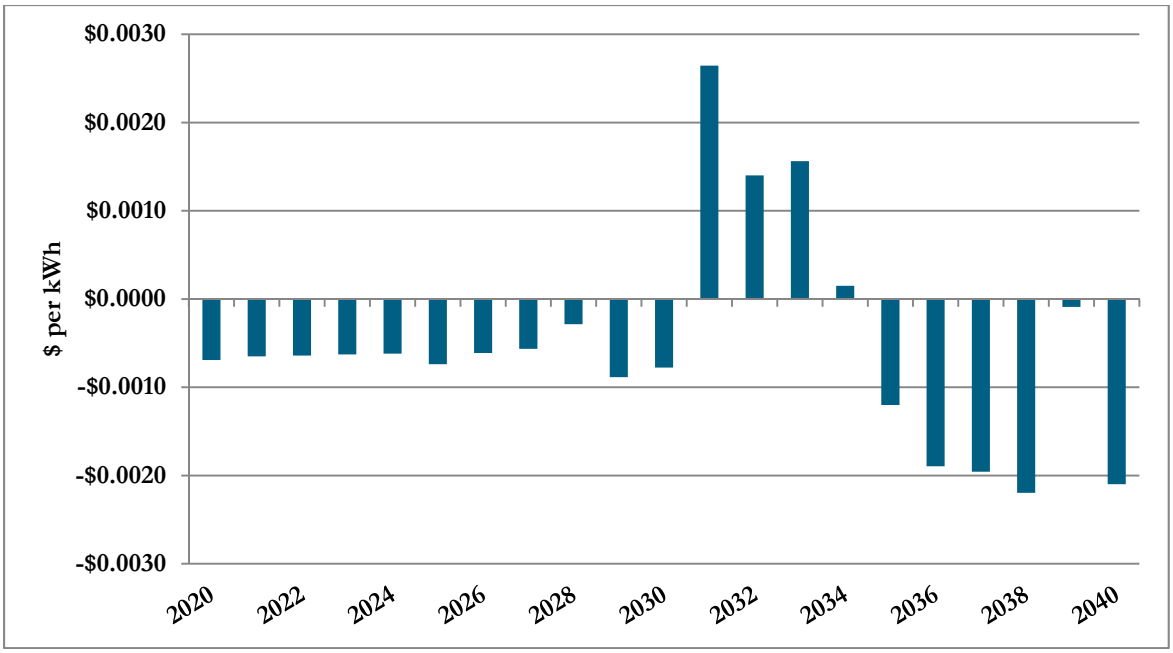


* *Notes: National energy cost forecast from Energy Information Administration (EIA) Annual Energy Outlook 2019, Table Energy Supply, Disposition, Prices and Emissions – Reference Case. End use prices, all sector average.*[9] The Preferred Plan and Reference *Plan lines include the costs of Solar Rewards*Community.*

[9] *See* https://www.eia.gov/outlooks/aeo/data/browser/#/?id=8-AEO2019&region=0-0&cases=ref2019&start=2017&end=2050&f=A&linechart=~ref2019-d111618a.70-8-AEO2019&ctype=linechart&sid=ref2015-d021915a.70-8-AEO2015~ref2019-d111618a.70-8-AEO2019&sourcekey=0 The EIA's Annual Energy Outlook was published in January 2019. The report is available at https://www.eia.gov/outlooks/aeo/pdf/aeo2019.pdf.

Figure 6 below demonstrates the actual impact implementation of our Preferred Plan would have on our customers' bills. We note that the Preferred Plan's average estimated rate impact, relative to the Reference Case, in any given is well under $0.01 per kWh.

Figure 6: Incremental Rate Impact of Preferred Resource Plan
State of Minnesota – All Customers



VII. CONCLUSION

The Preferred Plan we propose in this 2020-2034 Upper Midwest Resource Plan reflects extensive collaboration with stakeholders as well as independent expert analysis. Our Preferred Plan proposes to eliminate coal, add even more renewables, and continue our industry-leading energy efficiency and demand response programs, all while preserving reliability and affordability for our customers. It also meets the varied interests of our five-state Upper Midwest region. By planning ahead and charting an orderly, gradual transition of our generation fleet, we believe we can achieve all of these goals while managing the impacts to our host communities and employees, preserving the reliability and stability of our system, and maintaining affordability for our customers. For these reasons, as discussed throughout this filing, we believe our Preferred Plan is in the public interest and merits Commission approval.

Xcel Energy®

Building a Carbon-free Future | CARBON **REPORT**

To our **Stakeholders:**

Xcel Energy is committed to serving customers, and that includes responding to the concerns of many customers around the risk of climate change. National and international studies paint a sobering picture about this risk and call for nothing less than a transformation of our industry to help address it. While that transformation will be challenging, we see an opportunity for our company and those we serve to significantly reduce greenhouse gas emissions reliably, safely and at a low cost.

In 2018, we reduced carbon emissions from the electricity that serves our customers by 38 percent compared to 2005 levels and plan to do even more. As technologies have improved and costs have fallen, we are making significant changes — more than we imagined possible a decade ago — without compromising the reliability or affordability that our customers expect. We need all three components — clean, reliable and affordable — to make this transition work.

As we carry out Xcel Energy's vision to be a preferred and trusted energy provider, leading the clean energy transition continues to be a strategic priority for us. It's helping to achieve our other two strategic priorities as well — to keep customer bills low and enhance the customer experience.

We're a national leader in wind energy and are harnessing it through our Steel for Fuel strategy, which we expect to reduce costs for customers. We also offer a leading portfolio of energy efficiency and renewable choice programs because an increasing number of customers want to power their homes and businesses with clean energy and take steps to reduce their own carbon footprints.

While our existing efforts are significant, we want to do even more and do it sooner than anticipated. That is why I set an ambitious vision to reduce our carbon emissions 80 percent from 2005 levels by 2030. Longer term, we aspire to serve our customers with carbon-free electricity by 2050. The technology to achieve this aspiration isn't commercially available yet, but I believe it can be available if we make it a priority today.

In this report, we discuss our vision, including the opportunities, risks and challenges we face getting there. We describe how our carbon transition can have an even larger impact in other sectors, such as transportation. We also show how our commitment compares to the targets of international climate agreements.

Xcel Energy is leading the clean energy transition. We know from experience that our goals are ambitious. This change will require collaborative, long-term solutions that are cost effective as well as advanced clean energy technologies. Broad stakeholder support, smart public policy and favorable economics are essential factors in this ongoing transformation.

We can't achieve this transition alone — it will take all of us working together. I look forward to your partnership.

Sincerely,

Ben Fowke
Chairman, President and CEO

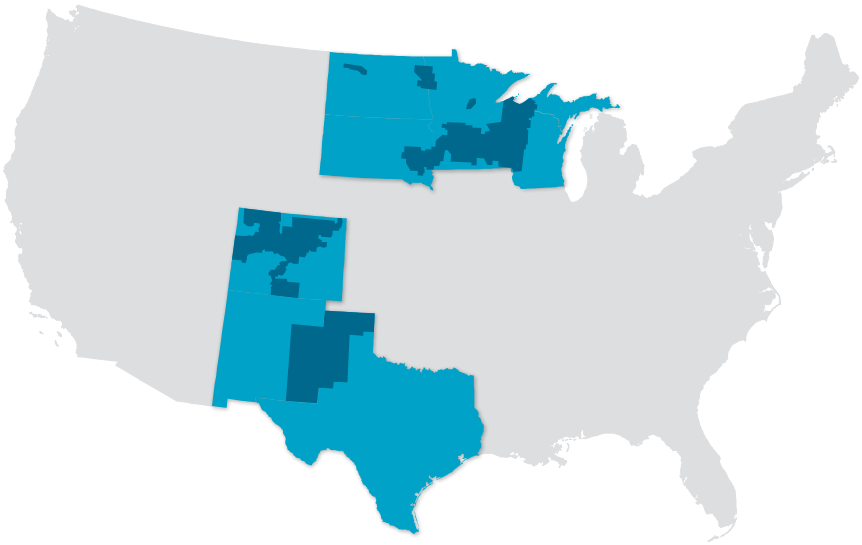
About Us

Xcel Energy is a major U.S. electricity and natural gas company with annual revenues of $11.4 billion. Based in Minneapolis, we operate in eight states and provide a comprehensive portfolio of energy-related products and services to 3.6 million electricity customers and 2 million natural gas customers.

Addressing climate change is a priority for many of our customers, investors and key stakeholders, and is a priority for us as well. In delivering on our strategic focus to lead the clean energy transition, we are successfully reducing carbon emissions and providing clean energy solutions from a variety of renewable sources, reliably and affordably for customers.

More information on our clean energy strategy, corporate governance and risk management is available at **xcelenergy.com** in our corporate reports, including Xcel Energy's Annual Report, Proxy Statement, Corporate Responsibility Report and EEI Environmental, Social, Governance and Sustainability Report.



Forward Looking Statements

The material in this report contains forward-looking statements that are subject to certain risks, uncertainties and assumptions. Such forward-looking statements include projections related to emission reductions, changes in our generation portfolio, planned retirements, and planned capital investments and are identified in this document by the words "aim", "aspire", "assuming", "believe", "could", "expect", "may", and similar expressions. Actual results may vary materially. Factors that could cause actual results to differ materially include, but are not limited to: general economic conditions, including the availability of credit, actions of rating agencies and their impact on capital expenditures; business conditions in the energy industry: competitive factors; unusual weather; effects of geopolitical events; including war and acts of terrorism; changes in federal or state legislation; regulation; actions of regulatory bodies; and other risk factors listed from time to time by Xcel Energy in its Annual Report on Form 10-K for the fiscal year ended Dec. 31, 2018 (including the items described under Factors Affecting Results of Operations) and the other risk factors listed from time to time by Xcel Energy Inc. in reports filed with the SEC.

Aspiration for a **Carbon-free** Energy Future

For more than a decade, Xcel Energy has demonstrated leadership on clean energy — proactively reducing carbon emissions at levels that currently surpass state and federal goals. This environmental commitment is woven into our company's strategy, governance, executive compensation and daily operations.

To respond to growing stakeholder expectations, we have regularly established and achieved increasingly ambitious carbon reduction goals.

Where We Aim to Be

Our vision for the future includes industry-leading goals shown in Figure 1. In this report, we demonstrate how our goals align with an emissions trajectory needed for the electric power sector to meet the goals of the Paris climate agreement.

By 2030, we aim to reduce carbon dioxide emissions 80 percent below 2005 levels company-wide. This means that by 2030, our annual carbon emissions from the electricity that serves our customers will be about 17 million tons, or 80 percent lower than in 2005. We believe these emission reductions can be achieved cost effectively with continued fleet transition and operational changes, and with the renewable, carbon-free generation and energy storage technologies available today.

By 2050, we aspire to provide our customers across all states with 100 percent carbon-free electricity. In the next 30 years, we will transition to serve our customers with electric resources that emit zero carbon dioxide emissions. To fulfill this aspiration, we will continue to increase renewable energy sources on our system, as well as technologies that enable renewable integration. We will need new carbon-free dispatchable technologies — technologies not yet commercially available at the cost and scale needed to achieve our 2050 aspiration. Because of this, there needs to be significant research and development to ensure we have these technologies to deploy in the coming decades.

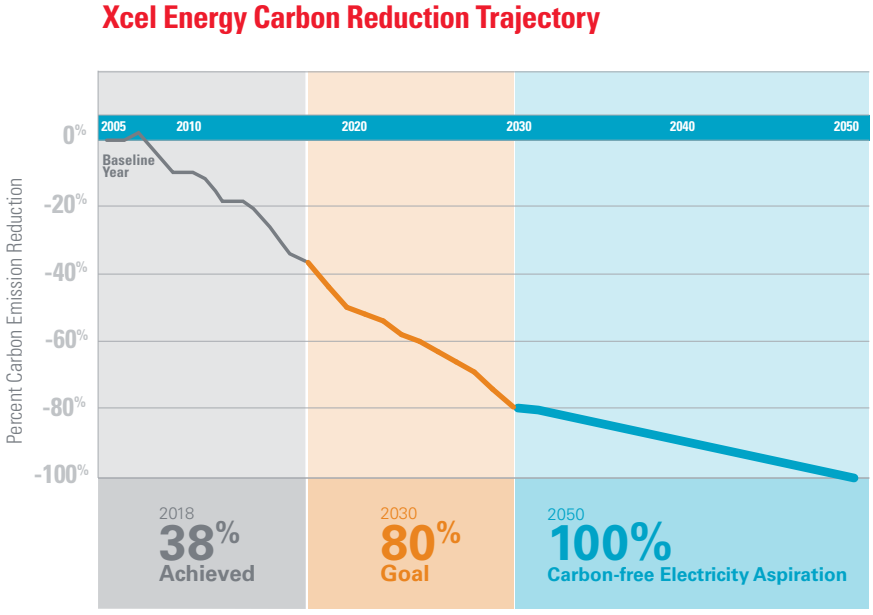


Figure 1: Our vision for the clean energy transition 2030 and 2050

The Path to Get There

We know that climate change is an urgent issue for many of our policy makers and a growing concern of our customers who want to help make a difference. Planning for the transition to a clean energy future today will allow us to deliver the product our customers want and achieve reductions that our policy makers are increasingly demanding. By acting now, we increase our chances to achieve these goals while assuring that our system remains reliable and our prices affordable. These last two points are critical to our success. The electricity we deliver is an essential service that powers the economy and keeps our customers comfortable and safe.

While we move through this transition, we need to make sure that power will be there when our customers need it and that the prices we charge are affordable to all customers , both residential and commercial. To accomplish this, we will build upon four focus areas that are transforming our system and delivering clean, reliable, low-cost power to customers today.

These focus areas include:

- Investing in wind and solar under our Steel for Fuel strategy and offering customers more renewable energy options
- Helping customers manage their energy usage and bills through efficiency and rebate programs and encouraging strategic electrification of other sectors, such as transportation
- Maintaining our carbon-free nuclear plants in the Upper Midwest
- Transforming the energy grid by retiring or reducing the operation of aging coal plants and replacing their energy with low-carbon natural gas, renewables and advanced technologies

Looking ahead to 2030 and 2050, we plan to continue this progress. Our vision is not a single plan or initiative. Instead, it will guide the policies that we support and the resource plans that we expect to file in our states over the coming decades. As we advance these efforts, stakeholders are essential and will help to influence the outcomes. Because of this, we plan to continue working collaboratively with customers, nongovernmental organizations, policy makers and others to identify and implement pragmatic solutions to make our goals possible.

In setting our goals, we did sensitivity analysis to identify key elements and variables that could affect our plans. There are a variety of cost-effective pathways to an 80 percent carbon reduction by 2030, and resource plans in our jurisdictions will determine the exact resource mix. However, through the pathways we explored, we have identified the following common elements that we know will be part of the plans:

- We anticipate adding thousands of megawatts of wind and solar power to our system and incorporating both natural gas and storage resources to help balance high levels of renewables
- Strategic electrification of certain end uses will help create flexible demand
- We will seek to operate our nuclear plants through at least the remainder of their licenses, and we will need to retire additional coal units or change their operations to minimize emissions affordably and reliably
- In addition, we will need to make critical investments in supportive infrastructure, such as transmission

As we transition our system and retire plants, we will need to assure that we do so in a way that our company remains financially healthy and that acknowledges the financial impacts of plant retirements and the replacement investment on our investors. Just as we serve other stakeholders, we must provide our investors with value to encourage them to provide the capital necessary to support these plans. There are many ways to accomplish our carbon vision, but the ability to own these replacement resources is clearly an important consideration, as investors support companies that grow their earnings power. This ownership also helps to reduce risk to customers and is fundamental to ensuring our financial viability and ongoing ability to efficiently invest in day-to-day infrastructure needs as well as clean energy.

To reach our 2050 aspiration, there must be more action around the research, innovation and demonstration of advanced technologies. We need, clean technologies that can be dispatched to balance the peaks when customer use exceeds renewable generation and valleys when renewable generation exceeds customer use. Cost-effective, low-carbon and carbon-free dispatchable resources will be required to remove the remaining carbon from the system to serve customers with carbon-free electricity. Technology advancement is key to the long-term success of our strategy.

Analysis Related to **Our Vision**

In planning our future carbon transition, we have reviewed the research on climate science to confirm the effectiveness of our goals. A trio of climate reports — from the Intergovernmental Panel on Climate Change (IPCC), the U.S. Global Change Research Program and the UN Environment Program — examine potential climate change impacts and the greenhouse gas reductions needed to meet the targets of the Paris climate agreement. While providing broad context for our analysis, none of these reports includes actionable guidance for utility decision making or for individual company greenhouse gas goals.

We also participate in an Electric Power Research Institute (EPRI) project that is analyzing the science around climate scenario analysis and emission goal setting. While providing useful insights about global, regional and electric sector emissions consistent with limiting temperature increases to 2 C, the EPRI project does not provide company-specific comparisons to the Paris climate targets.

To bridge this gap, we hired experienced climate modelers at the University of Denver to compare Xcel Energy's goals to the Paris climate targets. We compared our goals to electric power sector emissions in industrialized countries, in IPCC scenarios consistent with a high probability of achieving the 2 C and 1.5 C temperature goals in the Paris climate agreement.

The Paris Climate Agreement

In December 2015, the international negotiations of the United Nations Framework Convention on Climate Change (UNFCCC) produced the Paris climate agreement, with the goal of "holding the increase in the global average temperature to well below 2 C above preindustrial levels and pursuing efforts to limit the temperature increase to 1.5 C above preindustrial levels, recognizing that this would significantly reduce the risks and impacts of climate change."[1]

The Paris climate agreement does not establish goals, mandates or even guidance for individual economic sectors or companies. This makes it challenging to address the relationship between the agreement's goals and company-level targets. Its temperature goals represent a global ambition, pursued through nationally determined contributions and subsequent national and sub-national (e.g., state) policy decisions about how to allocate the emission reduction burden across sectors, industries and individual companies.

IPCC Special Report

The IPCC in October 2018 published a Special Report on Global Warming of 1.5 °C. The IPCC estimates that warming to date is about 1 C above average preindustrial temperatures and that warming is likely to reach 1.5 C between 2030 and 2052.[2] The report evaluates human and natural impacts of climate change associated with global warming of 1.5 C and compares these to impacts at 2 C or more. The IPCC then explores what global greenhouse gas reductions would be needed, on what timeframe, to limit warming to 1.5 C. It estimates that global net human-caused carbon dioxide emissions would need to peak within the next few years, then fall dramatically, reaching net zero by around 2050 (meaning that after that point, carbon emissions are balanced by carbon removal.) The report indicates that allowing global temperatures to temporarily overshoot 1.5 C, but return below 1.5 C by 2100, would require greater reliance on negative emission technologies after mid-century. To stay below or only temporarily exceed 1.5 C, global emissions in 2050 would have to be between 71 percent and 129 percent below 2010 levels.[3]

US Fourth National Climate Assessment (NCA4)

The U.S. Global Change Research Program in November 2018 released its Fourth National Climate Assessment, summarizing the latest scientific understanding of climate change impacts, risks, mitigation and adaptation, both nationally and by regions of the United States. The report finds that climate change is having significant impacts on U.S. communities, the economy, trade, water, public health, ecosystems, infrastructure, energy systems, agricultural productivity, oceans and coastlines. Potential impacts on the electric sector include reduced generation efficiency at thermal plants, power outages, grid reliability challenges, fuel transport, changing wind patterns, increased electricity demand for cooling and reduced natural gas demand for heating.

Under a high emissions future, NCA4 finds that "climate change is projected to impose substantial damages on the U.S. economy, human health and the environment. Under scenarios with high emissions and limited or no adaptation, annual losses in some sectors are estimated to grow to hundreds of billions of dollars by the end of the century."[4] However, NCA4 also finds that greenhouse gas reductions sufficient to keep the world on a lower warming pathway could still avoid or significantly reduce these damages — and that the earlier the reductions, the greater the chance of avoiding the worst impacts.

UN Emissions Gap Report

The U.N. Environment Programme (UNEP) in November 2018 released its annual Emissions Gap Report, which assesses the status of countries' "nationally determined contributions" under the Paris climate agreement. The report finds that global carbon dioxide emissions increased in 2017 after staying relatively flat for three years, reaching 53.5 billion metric tonnes CO2e (GtCO2e) and show no signs of peaking in the near term. Without additional efforts, UNEP predicts global warming of about 3 C by 2100. UNEP estimates a gap of 13 GtCO2e per year by 2030 between global emissions under the nationally determined contributions and the annual emissions needed to achieve the 2 C target (for the 1.5 C target, a gap of 29 GtCO2e.) UNEP finds it is still possible to bridge the gap and contain warming below 2 C and 1.5 C, but this will require aggressive reductions by 2030, particularly in emission scenarios that are more pessimistic about the potential for negative emissions (i.e., carbon removal technologies) later on.

EPRI Research

Because the reports summarized above do not include guidance specific to electric utilities or other industries, Xcel Energy also participates in a multi-utility project convened by EPRI to examine the current state of the science around climate scenario analysis and company greenhouse gas goals.[5] EPRI released a report in fall 2018 that takes stock of current scientific understanding and provides analytical guidance, titled Grounding Decisions: A Scientific Foundation for Companies Considering Global Climate Scenarios and Greenhouse Gas Goals. We outline here a few key findings from the report.

Figure 2 illustrates the many variables defining the relationship between global temperature goals and company-level greenhouse gas emissions. Uncertainties in the relationships between each variable result in ranges of global, country, sector and individual company emissions consistent with a temperature goal. This means there is no single or uniform target that can be applied to all companies and is appropriate in all plausible futures. Nonetheless, ranges can be identified that are consistent with achieving the temperature goals.

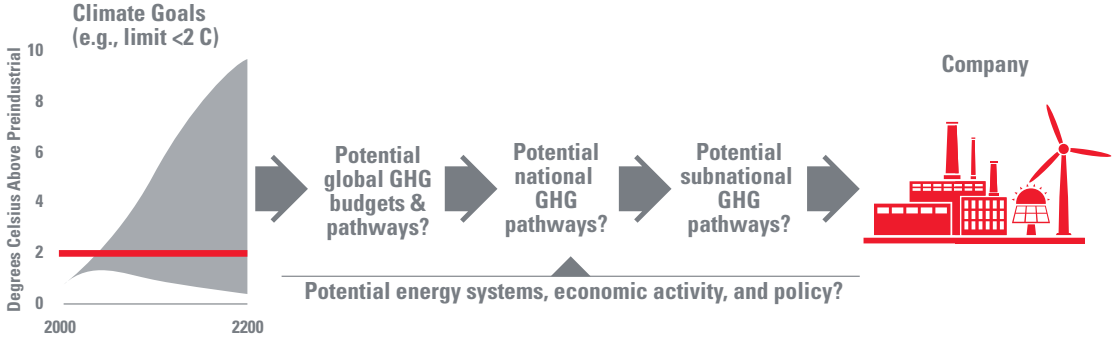

Figure 2: The relationship between global climate goals and company-level targets. Reproduced from EPRI 2018, page 2-1.

EPRI draws on the IPCC Fifth Assessment Report (AR5) emission scenario database and other scenarios to characterize current understanding of these relationships. Among other things, the EPRI study identifies sets of global, regional and electric power sector emission scenarios consistent with different probabilities of limiting global average temperature increase to 2 C.[6]

Figure 3, reproduced from the EPRI report, shows the range of global carbon dioxide scenarios consistent with a 40 percent or greater chance of limiting global warming to 2 C. The left-hand chart shows that a broad range of scenarios, rather than a single scenario, is consistent with this temperature goal. It also shows that scenarios that increase emissions in the near term generally require significant negative emissions after mid-century to offset the near-term increase and achieve the temperature goal.[7] The right-hand chart shows the much smaller range of scenarios that can achieve the temperature goal with the same 40 percent probability, if negative emissions technologies are unavailable.

The EPRI study also presents sets of regional and electric sector emissions pathways consistent with 2 C. However, as discussed by EPRI, these results are dependent upon global assumptions — in particular, global economy-wide policy design and technology availability assumptions that facilitate reducing carbon with electricity. These are important uncertainties for electric power companies to evaluate, and sub-global scenario results should be used with caution and with these uncertainties in mind.

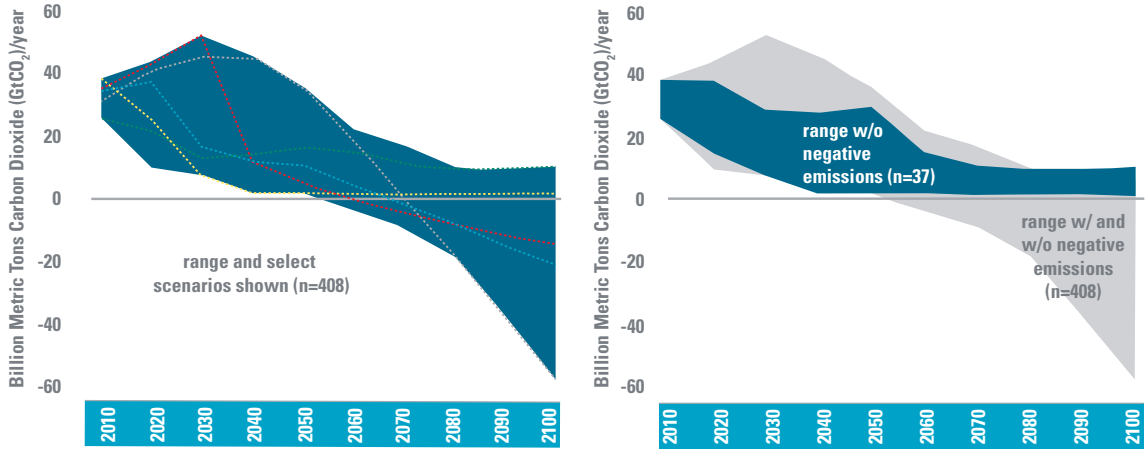

Figure 3: Global net carbon dioxide pathway ranges consistent with a 40 percent or greater chance of limiting warming to less than 2 C. Reproduced from EPRI 2018 and supporting material.

EPRI's report provided key insights for our subsequent work with the University of Denver. First, there is a broad range of emissions pathways consistent with a given probability of achieving a temperature goal. We need to consider our carbon goals relative to this range and the uncertainties it represents, including uncertainties about policy, technology availability and reductions assumed to be achieved in sectors other than electricity. Second, we can choose to compare ourselves to pathways with higher likelihood of achieving temperature goals, as well as compare to Xcel Energy to sub-global pathways such as electric power sector emissions. However, in doing so, it is important to recognize the assumptions, challenges and uncertainties embedded in such an analysis and their implications for our goals.

Finally, many IPCC scenarios assume the availability of significant negative emissions after mid-century, in some cases offsetting emission increases in the near term, to achieve the temperature goal. This is particularly true of the 1.5 C scenarios. Because negative emissions electricity technologies are not commercially available today, to be conservative we compared ourselves only to carbon scenarios that do not include negative emissions technologies within the electric power sector in industrialized countries (but may include negative emissions in other regions and sectors.) If negative emissions electricity technologies become available, we would consider them along with other options for providing customers reliable, affordable clean energy. Because our analysis does not rely on these technologies to reach our goals, we plan to continue to reduce carbon emissions aggressively in the near term, consistent with cost (which is also influenced by need) as well as reliability.

Comparing Xcel Energy to the Paris Climate Agreement Goals

EPRI did not attempt to identify company-specific emission trajectories corresponding to the global temperature goals because of the increasing uncertainty at higher levels of resolution. However, investors and others routinely ask Xcel Energy to compare company-specific emissions to the temperature goals, so we needed to go a step further. We commissioned an analysis by experienced climate modelers at the University of Denver, including a lead author on the IPCC's forthcoming Sixth Assessment Report, to compare our goals to electric sector carbon dioxide emission scenarios consistent with limiting warming to both 2 C and 1.5 C. We provided the modelers our carbon emission forecast and goals, and had them compare these to electric sector carbon emission scenarios consistent with 2 C and 1.5 C. We set three constraints on their analysis:

- Focus on scenarios categorized by the IPCC as having a high probability of achieving the temperature goals
- Compare Xcel Energy to the electric power sector in industrialized countries
- Exclude scenarios that rely on negative emissions technologies within the electric sector

On pages 11 to 13, the University of Denver modelers summarize briefly their approach and findings.

Xcel Energy targets and limiting warming to less than 2 C and 1.5 C

By Dr. Brian O'Neill and Steve Hedden

Climate researchers have carried out a large number of studies of how much and how fast greenhouse gas emissions would have to be reduced in order to achieve the Paris climate targets of limiting warming to less than 2 C, or even to below 1.5 C. We drew on the results of those studies to compare Xcel Energy's emissions reduction goals to emissions pathways consistent with the Paris climate targets. In those pathways, global carbon emissions generally decline to zero (in net terms) by around 2070 or later to stay below 2 C and by around 2050 to stay below 1.5 C.

However, emissions associated with one company in one country are just a fraction of global emissions, so we compared Xcel Energy's goals to a more detailed and more relevant set of results from these studies: net carbon emissions from the electric power sector in industrialized countries. We found that Xcel Energy's goals represent reductions that are consistent with, and in most cases larger than, those that occur in this sector in scenarios that achieve the Paris climate targets.

Approach

The Intergovernmental Panel on Climate Change report from October 2018[8] assessed the scientific literature on emissions scenarios consistent with the Paris climate targets. To support that assessment, researchers created a database of 416 published emissions scenarios.[9] The scenarios were developed using computer models that calculate the greenhouse gas emissions and warming that would result from the production and consumption of energy, food, transportation and other goods in regions around the world over the coming decades. The future is uncertain, so these scenarios investigate a wide range of possibilities about how fast population, incomes and energy demand may grow and what kinds of climate policies may be pursued to achieve the Paris climate targets.

We compared the Xcel Energy goals to a subset of these scenario results. First, we selected two sets of global greenhouse gas emission scenarios from the database: those that would be likely (defined as having a greater than 66 percent chance) to stay below 2 C, and those that would be more likely than not (defined as having a greater than a 50 percent chance) to stay below 1.5 C or to only slightly (and temporarily) exceed that level.[10]

Next, we extracted results from these scenarios for carbon dioxide emissions from the electric power sector in industrialized countries.[11] These outcomes from the scenario database are the best comparison available to Xcel Energy goals. Models that produce emissions scenarios do not represent individual companies, nor even individual countries. Results are reported in the database as totals for groups of countries for different sectors of the economy. By using results for the electric sector in industrialized countries, we can compare Xcel Energy goals to emissions pathways that occur on average across the same sector of countries at similar levels of economic development to the United States.

Finally, we excluded scenarios in which net carbon dioxide emissions from the industrialized country electric sector are negative at any time in the future, through 2100. (Note that these scenarios could still include negative emissions in other sectors and regions.) In the electric sector, net negative emissions could result from technologies like biomass energy with carbon capture and storage (BECCS) that generate electricity while removing carbon from the atmosphere. Scenarios with these technologies often allow for higher global emissions in the first few decades that are compensated for by negative emissions later in the century. However, these technologies are unproven at large scales and involve possible risks to biodiversity and food prices due to the large amount of land that may be required for growing biofuels.

Our selection process left us with 17 scenarios consistent with the 2 C target and five scenarios consistent with the 1.5 C target, a reflection that achieving the lower target without net negative emissions in the electric power sector is relatively uncommon in the scientific literature.

Results

The comparison in Figure 4 shows that Xcel Energy's 2030 and 2050 goals represent emissions reductions that are larger than those that occur in the electric sector of industrialized countries in most of the global emissions scenarios likely to limit warming to below 2 C. Xcel Energy's goals are also within the range of reductions that occur in the limited number of scenarios achieving the 1.5 C target. These figures show scenario results to 2050. Beyond 2050, these scenarios generally indicate low or zero net carbon emissions continuing through the end of the century.

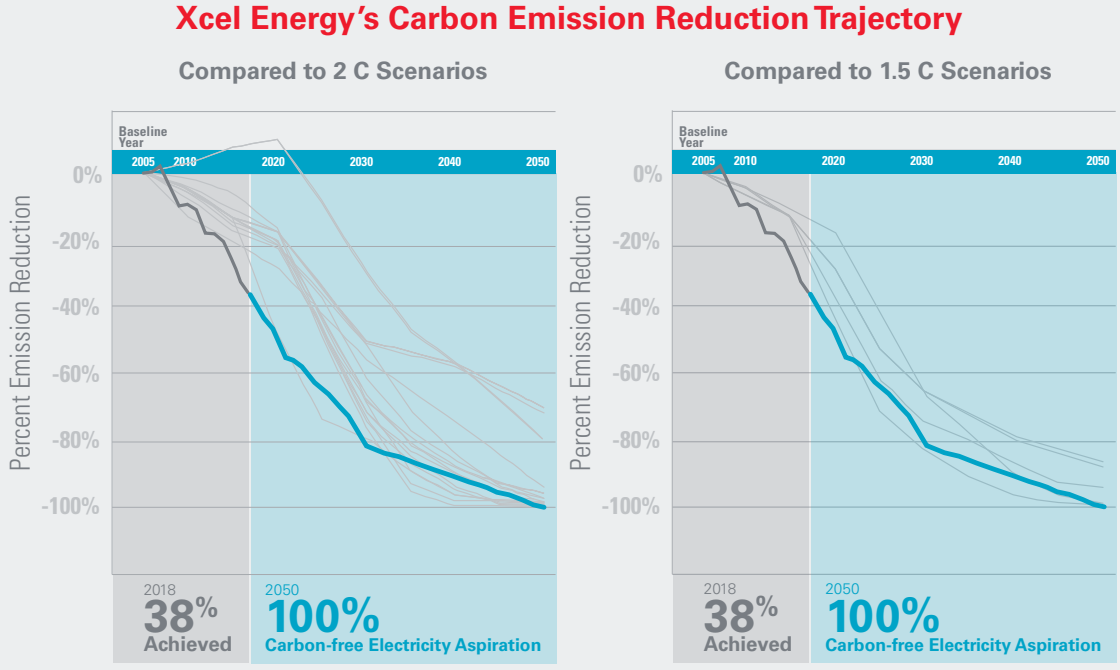

Figure 4: Xcel Energy carbon emissions reduction goals (in blue, with historical emissions in dark gray) compared to scenarios of emissions from the industrialized country electric power sector (in light gray). Emissions scenarios are from global scenarios likely to remain below 2 C warming (left) or more likely than not to avoid 1.5 C warming (right) without significantly exceeding that level. Emissions expressed as a percent reduction relative to levels in 2005.

Caveats to this analysis

To date, most company-level greenhouse gas scenario analysis has focused on 2 C rather than 1.5 C, in part because of the much greater uncertainty about the attainability of limiting warming to 1.5 C. The IPCC notes that limiting warming to 1.5 C may involve unprecedented actions.[12] Without taking a position on the attainability of 1.5 C, in this analysis we have assessed Xcel Energy's goals in relation to both temperature goals. We have chosen to include the 1.5 C scenarios because while that goal is unquestionably harder to attain than 2 C, experience shows that the scale and pace of technological change often outpaces our expectations today. Because of this — and because the IPCC Special Report makes clear that climate risks and damages, while not zero at 1.5 C, are substantively less than at 2 C — we believe it makes sense to include it in our analysis.

Any multi-decade analysis of company- or sector-level carbon dioxide emission trajectories relative to the global temperature goals involves inherently uncertain assumptions about economic growth, technologies, policy and global coordination or lack thereof. If those assumptions are not borne out — e.g., technologies do not develop as expected, economic growth is more carbon intensive than assumed, emission reductions (or negative emissions) assumed to occur in other sectors or regions do not materialize, etc. — then the industrialized country electric sector emissions consistent with a given probability of achieving the temperature goals could change.

We have endeavored to make conservative assumptions in this analysis. For example, we focus only on scenarios with relatively high likelihoods of achieving the temperature goals and exclude scenarios that rely on net negative emissions technologies within the electric sector. Also, we examined our conclusions to ensure that they do not change fundamentally when varying key assumptions, such as allowing net negative emissions in the electric sector, and that they do not rely on unreasonably large assumed reductions in other regions. For a fuller discussion of these issues, see our full report.[13]

Brian O'Neill is professor at the Josef Korbel School of International Studies at the University of Denver and director of Research at the Korbel School's Frederick S. Pardee Center for International Futures, whose mission is to explore, understand and shape alternative futures of global change and human development. He is currently a convening lead author for the IPCC's Sixth Assessment Report and was an author on the United States' Fourth National Climate Assessment.

Steve Hedden is lead system administrator at the Pardee Center and is a coordinating lead author of the United Nations Environmental Programme's (UNEP) sixth Global Environmental Outlook (GEO6.)

Our Conclusions on the Analysis

Participating in the EPRI research, and subsequently engaging University of Denver climate modelers to compare our carbon vision against the Paris climate targets, helped to validate that our goals are consistent with electric sector emissions in scenarios likely to achieve the targets. Our goal to reduce carbon emissions 80 percent by 2030 and aspiration to serve customers with carbon-free electricity by 2050 appear largely consistent with the industrialized country electric sector carbon reductions in scenarios that achieve the Paris climate targets, even acknowledging the many uncertainties and embedded assumptions in any such analysis.

More specifically, Figure 4 shows that our carbon dioxide reductions achieved to date (shown by the dark gray line) fall below all the scenarios corresponding to a high probability of achieving the 2 C and 1.5 C goals. Our trajectory from today to 2030 falls below all but one of the scenarios for both temperature goals. Our aspiration for 2050 lies well within the range of emission scenarios for both temperature goals. In addition, we note that our carbon dioxide emission reduction trajectory from 2030 to 2050 is represented as a simple straight-line projection since we have no resource plans that extend to 2050. Our actual reductions will not likely follow that smooth line and depending on cost and technology developments, and the future of our nuclear plants, could either decline or increase from the line in any given year.

Any climate scenario analysis has embedded assumptions and necessary simplifications. For our analysis, these include:

- Our actual carbon emissions will depend on our resource mix, renewable energy and natural gas prices, total load, degree of electrification of end uses currently reliant on other fuels, and many other factors. We typically run sensitivities for these and many other variables in our resource plans.

- Depending on the amount of electrification assumed, a very low-carbon electric power sector may enable significant greenhouse gas reductions in transportation, buildings and other sectors. Our strategy contemplates significant electrification of the economy. The scenarios shown here virtually remove carbon from the electric sector, but there could be scenarios in which it is cost effective for the electric sector to emit slightly more carbon while reducing carbon in other sectors and still achieving the economy-wide reductions necessary for the temperature goals.
- The cost effectiveness of any greenhouse gas reduction pathway depends to some extent on climate policy, which is not addressed here. If adopted, climate policy frameworks will determine costs to our customers, flexibility in achieving greenhouse reductions, and linkages to or coordination with other emitting sectors. Xcel Energy will continue to advocate for climate strategies that achieve greenhouse gas reductions at the lowest possible cost to customers while maintaining reliability. Since many IPCC scenarios envision significantly increased electricity use in transportation, buildings and industry in order to achieve economy-wide reductions, keeping electricity affordable will be crucial.
- The achievability and cost effectiveness of any greenhouse gas goal will also depend on how technology evolves, which we cannot predict for 2050 or even 2030. Our carbon transition will depend on a mix of renewable energy, energy storage, carbon-free dispatchable technologies and flexible demand that could enable us to achieve deep carbon reductions affordably and reliably.

Reporting and **Measuring Progress**

As an energy provider, we emit greenhouse gases as we provide electricity to our customers. The primary source of these emissions is from the combustion of fossil fuels to generate electricity, which makes up 99 percent of our total greenhouse gas emissions. Nearly all of our generation-related emissions are carbon dioxide. Because of this, it makes sense that we focus our strategy, goals and reporting on reducing carbon emissions.

The carbon emissions discussed in this report and other Xcel Energy reporting are from electric generating plants that we own and from electricity that we purchase from others. Xcel Energy sells a small portion of the electricity we generate into the market, and the carbon emissions from these off-system sales are excluded from our goal and goal reporting because the energy does not serve our customers. Also, it is likely that many companies purchasing the energy account for the emissions in their reporting, so including them in our reporting could result in double counting.

Our goal to reduce carbon emissions 80 percent by 2030 is based on absolute, company-wide emissions from the electricity that serves our retail and wholesale customers, measured from a 2005 baseline. Likewise, our aspiration to serve customers with carbon-free electricity by 2050 is company-wide.

Xcel Energy supports timely, transparent public reporting of carbon dioxide and other greenhouse gas emissions. Our comprehensive greenhouse gas reporting, from all parts of our business, is based on The Climate Registry and its Electric Power Sector Protocol, which aligns with the World Resources Institute and ISO 14000 series standards. Our company joined The Climate Registry as a founding member in 2007 to help establish a consistent and transparent standard for calculating, verifying and reporting greenhouse gases. Through The Climate Registry, we annually third-party verify, register and publicly disclose our greenhouse gas emissions.

Managing the Risks Associated with **Climate Change**

Over the next several decades as we make our carbon transition, we will continue to monitor and take steps to mitigate any risks along the way. Changing weather patterns, extreme weather conditions and other events, such as flooding, droughts, wildfires and snow or ice storms, can all impact our system in terms of system operability, customer demand, revenues, cost recovery and the health of regional economies.

We rely on routine business processes to identify and address these types of risks and emerging challenges. These include our risk management, resource planning and daily operations, as well as our continuous improvement and innovation initiatives.

Integrated Risk Management

Our integrated, multi-disciplinary risk management process creates accountability for managing risk across the company — from employees who are responsible for business compliance and adhering to our Code of Conduct, to senior executives and the board of directors who oversee risk management. Annually, executive leadership conducts a key risk assessment, considering materiality, timing and likelihood and controllability of risks. Management also identifies and analyzes risk through its business planning process and development of goals and key performance indicators, which include risk identification to determine barriers to implementing our strategy. While the assessment is broad, it includes the operational, policy and weather-related risks potentially associated with climate change. Findings are presented to the board of directors, which assigns oversight of critical risks among the board's four standing committees to ensure they are well understood and managed on an ongoing basis. We provide more information on our risk management process, including discussion of climate-related risks, in Xcel Energy's annual form 10-K.

Resource Planning

Our resource planning process is designed to manage capital-intensive investments over decades-long time horizons. Through this regulated process, we evaluate a range of scenarios and stress test our energy portfolio against important variables, including fuel prices, renewable energy and storage costs, transmission constraints and a variety of others. We use load forecasts to account for changing weather patterns, a key variable in explaining actual loads and in forecasting future loads. Load forecast sensitivities can also ensure our portfolio is sufficient to meet different needs created by electrification, which is likely to become more prevalent in a carbon-constrained future. Our resource planning also considers the costs and risks of potential carbon regulation and potential damages from climate change by applying a carbon proxy, allowing regulatory costs, and in some cases, externality damages to be considered in selecting resources.[14]

Operations

Maintaining reliable and resilient operations across generation, transmission and distribution means we constantly prepare for the unexpected. We use a suite of techniques to maintain a resilient system from water management to emergency preparedness. For example, our Monitoring and Diagnostics Center watches the operation of major generating units in real time, identifying potential issues before they occur. We also have predictive analytics and software tools that help avoid plant failures and can even address issues which may result in higher emissions or compromise reliability. Further, we have specific procedures in place to deal with extreme weather, flooding, drought or other conditions that may impact the operability of our plants. To better understand and address climate-related vulnerabilities on our system, we joined the Department of Energy's Partnership for Energy Sector Climate Resilience to work with others in the industry.

A Focus on Grid Resiliency

We continually invest and innovate to maintain and improve the resiliency of our energy grid. The following are several highlights from the many programs we are implementing to address potential system risks.

Under our Advanced Grid Intelligence and Security (Advanced Grid) program, we are upgrading the energy grid to better serve customers and enhance our ability to efficiently restore power and improve reliability. The program builds a platform that provides enhanced visibility and control of the energy grid through the integration of modern information system technology and traditional distribution systems.

In addition to maintaining emergency plans at all of our power plants and planning for extreme weather, we are also focused on successfully managing major storm events, responding quickly and providing information to customers as we restore service. The Edison Electric Institute has recognized Xcel Energy multiple times with its Emergency Recovery Award for outstanding storm response. These efforts extend beyond our service territory, with our crews on standby to help with recovery efforts across the country when hurricanes or other natural disasters strike.

To better integrate high levels of renewable energy, we have deployed sophisticated modeling tools to better dispatch our system. Working with the National Center for Atmospheric Research and its affiliate company Global Weather Corp., we helped develop the Wind WX system that utilities around the globe now use to make better commitment and dispatch decisions. It uses real-time, turbine-level operating data and applies sophisticated algorithms to forecast the amount of wind power that will be produced. Forecasts for a 168-hour period are provided every 15 minutes across Xcel Energy's entire service territory. As we integrate more solar on our system, we are working on similar innovations for solar forecasting.

Our vegetation management program is generally performed on a four- to five-year cycle for our distribution and transmission lines. In Colorado, we have established a Mountain Hazard Tree Program that helps us stay ahead of the tree mortality caused by Mountain Pine Beetles.

Since we provide electricity in drought-prone areas, water is a precious resource that we must carefully manage. A co-benefit of our transition to renewable energy is that we are also lowering our water footprint. Beyond this, we have a comprehensive water management program to minimize the risks of continued water usage, including innovative partnerships to access water during extreme drought periods. For example, we use treated effluent to cool power plants in Texas and New Mexico. This effluent is water that would otherwise not be used and is available during drought.

Opportunities to Lead the **Carbon Transition**

Utilities can play a key role in helping solve the challenges of climate change. According to the Energy Information Administration, the electric power industry collectively reduced carbon emissions 28 percent from 2005 to 2017.[15] This includes Xcel Energy's progress — having reduced emissions 38 percent already, we have plans underway to achieve more, as explained in this report.

As an industry leader in renewable energy and reducing carbon emissions, we have a strategic advantage in continuing to lead this transition. We have been able to provide scalable solutions to reduce the carbon footprint of the energy we provide, while continuing to deliver energy in a manner that is safe, reliable and affordable. As we continue to implement solutions to address emissions across our system, we can also provide customers with options to reduce their carbon emissions and help other sectors reduce carbon through strategic electrification.

Investing for the Future to Reduce Emissions

We must achieve our carbon transition while maintaining a modern, viable electric system, which is dependent on our ability to attract capital and investors. Transitioning to cleaner sources of energy to achieve our carbon reduction goals should consider utility ownership of replacement resources, as we need our investors to support this transition. Our capital plans also envision the need for additional transmission and advanced grid technology. By investing in these assets, we can improve service to our customers, introduce new options and support greater reliability and flexibility in the way energy is delivered. This financial component is important to our plans.

Xcel Energy operates in regions with some of the best wind and solar resources in the United States, and we are capitalizing on this. Our Steel for Fuel strategy calls for adding renewable resources at a net savings because the capital costs of projects are more than offset by future avoided fuel costs. Customers benefit from the clean energy that also helps to keep their electricity bills low.

These renewable projects are just one component of the resource plans that determine new investments. Through the resource planning process with state regulators, we develop comprehensive, cost-effective plans to transform our system, serve customers and advance our transition to clean energy.

Empowering Customers to Reduce Carbon Emissions

We know customers want cleaner energy and more renewable options, but also expect electricity that is affordable and reliable. The great advantage of our system-wide clean energy transition is that all customers are receiving lower-carbon electricity over time — our reductions are their reductions — at an affordable cost.

Some of our customers — from residential customers to corporations and cities — desire to go further faster, accelerating the system transition by setting goals to meet up to 100 percent of their own demand with renewable electricity or to reduce their overall emissions. To meet this demand from customers, we provide an increasing array of voluntary renewable choice products, including cost-effective options to procure up to 100 percent renewable electricity and a comprehensive portfolio of industry-leading energy efficiency programs.

Through our 2030 and 2050 carbon reduction vision, we can further help customers achieve their goals. They will continue to reduce the portion of emissions from their electricity consumption, while we transition our overall system to a diverse mix of cost-effective, low-carbon and carbon-free generation resources.

In addition, we expect that our planned investments in technologies to modernize the energy grid will enable us to deliver new solutions for customers and create a flexible energy grid that allows for two-way power flows from customer-connected devices or distributed energy resources.

Electrification of our Economy

As the nation's electricity supply becomes cleaner, attention has increasingly turned to other sectors of the economy to address climate change.

The transportation sector is now the nation's leading source of greenhouse gas emissions according to the Energy Information Administration.[16] This also applies to the states Xcel Energy serves. For example, data from Minnesota indicates transportation has surpassed electricity as the leading carbon emitter, and that carbon emissions from transportation are declining far slower than electricity — a clear indicator of the opportunity for transportation electrification.[17]

We believe that strategic electrification of certain end uses will be a key component — though not the only solution — for achieving economy-wide greenhouse gas reduction goals. If we continue to electrify transportation and power vehicles with carbon-free electricity by 2050, we can help address the climate challenge for that sector.

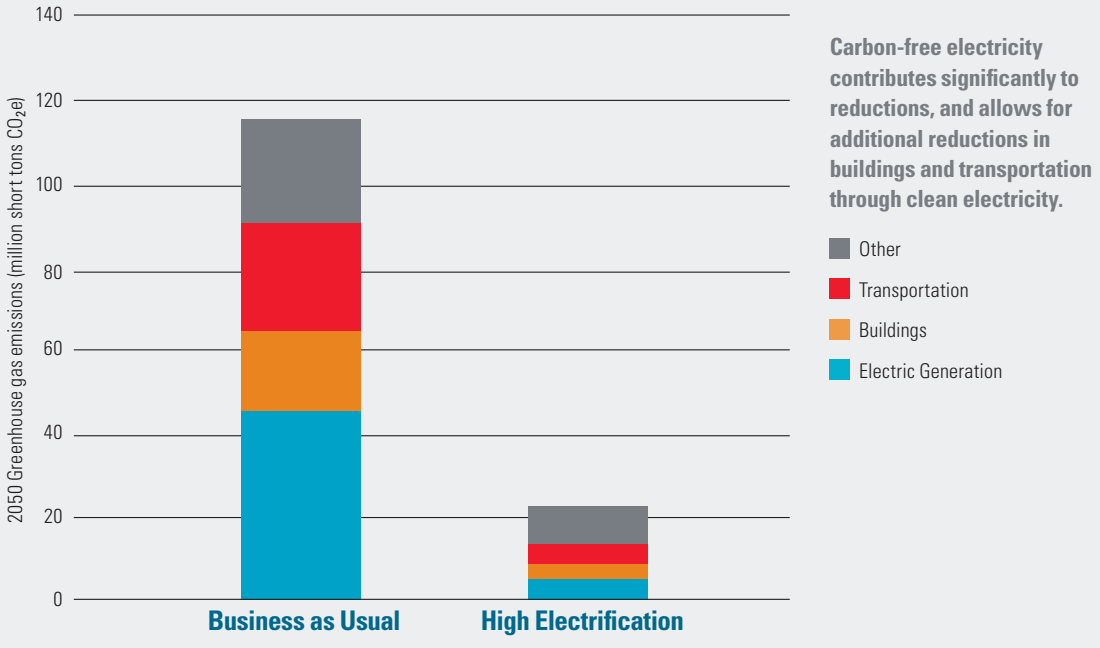
Low-carbon electricity and electrification: a Minnesota example

Removing carbon from electricity and electrifying other parts of the economy can be mutually reinforcing. Low-carbon electricity allows transportation, buildings and other major emitting sectors to reduce emissions. At the same time, flexible loads, such as electric vehicles and appliances that can charge at times of high renewable generation, may allow us to integrate more renewable resources than we could otherwise.

Xcel Energy engaged Energy+Environmental Economics (E3) to explore the feasibility of deep carbon reductions, both for the Xcel Energy system and for Minnesota statewide. E3 created a Minnesota PATHWAYS model looking at how the state could achieve its statutory economy-wide goal to reduce greenhouse gas emissions 80 percent from 2005 levels by 2050, with a primary focus on electricity, transportation and buildings.

The chart below illustrates this potential, focusing on 2050. It compares a business-as-usual scenario in which carbon is not reduced from electricity, and there is little or no electrification of other sectors, to what could be achieved in a "high electrification" scenario designed to meet the state's economy-wide 80 percent reduction goal. In this scenario, virtually all vehicles, space heating and water heating switch to electric alternatives by 2050. To supply these new loads, total statewide electricity demand in 2050 is 60 percent higher than 2015. Meanwhile, the electric sector reduces carbon, supplying over 90 percent carbon-free electricity in 2050. As a result, direct carbon emissions from electricity are reduced by about 40 million tons, as shown by the blue bars. Emissions from buildings, transportation and other sectors also decrease dramatically, with electrification enabling 35 million tons of that reduction through low-carbon electricity. Just as electricity is an essential service, natural gas service is as well, as it plays a critical role in keeping our customers comfortable and safe. When we review these options, we need to keep the affordability of space heating a primary objective along with the affordability of our electric business.

Carbon Reductions in the Electric Sector Drive Compounding Reductions throughout the Economy



Credit: Energy+Environmental Economics.

Xcel Energy's Electric Vehicle Strategy

The future of transportation is dramatically changing to include more electric-powered transportation options than ever before — as well as more autonomous features in vehicles and new (often shared) mobility services. Utilities are uniquely positioned to work with customers, communities and electric vehicle (EV) stakeholders to ensure this change benefits all customers, the environment and the energy grid that we all rely upon.

Through our current EV strategy, we are focused on:

- Making it easier for customers — from individual households to public and private sector fleets — to adopt EVs
- Creating the infrastructure needed to charge EVs
- Establishing time-varying rates and technological controls to ensure that EVs can charge as much as possible on low-cost, low-carbon energy

While EVs create a significant opportunity for drivers and fleet operators to save on fuel and other costs, barriers exist to wider-scale adoption, such as customer awareness, high up-front costs and the availability of charging infrastructure. Our plans will help overcome these barriers by developing new services, piloting them and then rolling out our most successful ideas to customers on a broader scale.

In Minnesota, we are engaging customers who are interested in adopting electric vehicles and buses. We hope to better understand their needs and barriers to adoption so we can work collaboratively toward solutions that could benefit all customers down the road. We expect these discussions will provide opportunities for us to pilot a variety of solutions that will inform our stakeholders and policy makers so we can scale solutions best suited to benefit all Minnesotans in the coming years.

As we pursue our EV Plan, we are focused on these objectives:

- Empower customers with information, tools and options
- Increase access to electricity as a transportation fuel in an equitable manner
- Encourage efficient use of the power grid and integrate renewable energy
- Improve air quality and decrease carbon emissions
- Ensure reliability, interoperability and safety of equipment
- Leverage public and private funding opportunities
- Provide benefits to all customers, both EV drivers and non-EV drivers
- Ensure transparency and measure results

Driving **Change**

By mid-century, we aspire to serve customers with carbon-free electricity. Even though this goal is decades away, we are a long lead time business and should begin now to identify and address the barriers to reaching it — especially if we are to maintain the affordable, reliable service that customers need and expect.

After reviewing national and international studies on climate change and through our going work with stakeholders, we believe reducing carbon emissions reliably and affordably is a top priority and must be the primary focus of our clean energy transition. To effectively achieve this shared objective, we must remain disciplined and concentrate on those efforts that produce the greatest carbon reductions at the lowest cost to customers.

We are optimistic that by staying focused we can make this transition and have identified the following drivers that will make the change possible:

- Protect energy reliability and affordability
- Support from our states and stakeholders
- A constructive policy environment and framework
- Availability of cost-effective, carbon-free dispatchable technologies

While our vision is ambitious, we believe these drivers implemented together will make it possible to transform our operations and the industry overall. Our plan is to continue working proactively and collaboratively in all these areas and to advance the solutions that emerge.

Protect Energy Reliability and Affordability

Cost is a major consideration for our clean energy strategy, and so far, we have successfully reduced carbon emissions while keeping energy costs low for customers. In fact, the average Xcel Energy residential customer electric bill has decreased 3 percent in the past five years. Our residential electric bills are on average about $28 lower per month than the national average. In our largest service territories, Minnesota and Colorado, customer electric bills are 22 percent and 36 percent below the national average respectively. We must continue to develop and invest in cost-effective transformative plans and in technologies with proven economic value for customers.

Energy reliability is also a fundamental requirement. Today, we are achieving far greater levels of renewable energy on our system than the industry ever believed possible. There are hours on our system when renewable generation delivers more than 50 percent of customers' electricity, and at the end of 2018, we achieved an hourly renewable generation record of 72 percent on our Colorado system. We expect these hourly records to increase under our current plans, we project that renewables will generate almost half of our power on an annual basis by 2021. As we deploy more renewable energy resources, managing the stability and reliability of the energy grid becomes increasingly difficult with fewer resources that can be dispatched to manage the variability of wind and solar energy. We will be focused on how to make sure that we take care to have sufficient resources to meet swings in load and generation as our integration of more renewable energy becomes more challenging.

Support from our States and Stakeholders

By working with the states we serve, we have successfully executed our clean energy strategy and plans.

Our four operating companies work under regulated conditions largely determined by state public utilities commissions. Every few years, we go through a process to determine the resources necessary to serve customers' future energy needs. This state resource planning process is critical to ensuring reliable energy and maintaining reasonable customer bills. Our carbon vision is not a single resource plan. Implementing our clean energy transition and achieving our goals will happen through many iterations of resource planning before our state utilities commissions between now and 2050.

Stakeholder participation is an important component to resource planning, and stakeholder support is essential to our clean energy progress. We will continue constructive engagement with our customers, investors, regulators, environmental groups, community leaders, policy makers and others to develop solutions and implement plans to achieve our goals.

We believe this model of state leadership can go even further in driving cost-effective emission reductions and clean energy investment. If advanced, federal policy should encourage utilities to work with states and invest as the conditions are right — when customers and the economics and technology are ready and without imposing significant, unnecessary costs on utility customers.

A Constructive Policy Environment and Framework

We are proving that the vertically integrated utility model with regulatory oversight is a cost-effective way to transition the energy system and achieve significant carbon reductions. This model provides inherent system value through efficiency, optimization and economies of scale that benefit all customers. It also balances the allocation of risks and benefits between the utility, its customers and even different customer classes.

Every customer on the energy grid shares in the transition to clean energy and can credibly claim the same carbon reduction. Policies that enable large businesses to sign direct contracts with renewable developers, may help individual companies to achieve their goals. However, they do not provide all customers with affordable, carbon-free energy and may even result in a more expensive energy system overall.

We have seen remarkable examples of the transformation that is possible and know from experience that our ambitious carbon transition is achievable if stakeholders and policy makers continue to recognize the economic and environmental benefits that utilities provide. As we continue this transition and go above and beyond in reducing carbon emissions, there may be opportunities to provide appropriate incentive to encourage and reward the industry's progress toward carbon reductions economy-wide.

Large-scale, universal resources — conventional, renewable and advanced — are by far the most cost-effective electricity generating resources available. While distributed energy resources are important for customers who want to invest in them and may play important roles at the distribution system level, these resources cannot accomplish what large-scale resources do in terms of carbon reduction at scale. Public policy should recognize the economic benefits that large, universal resources provide to achieve our ambitious goals affordably and reliably for customers. Hidden and unfair subsidies to support high-priced resources only serve to increase the cost of clean energy and reduce the ability of the nation to make this transition.

Similarly, nuclear generation plays a vital role in our carbon transition and provides a significant portion of our carbon-free energy in the Upper Midwest. We need policies at the state and federal levels that allow us to continue the cost-effective operation of these important assets at least through the end of their current operating licenses.

We must also address emissions from fossil plants, especially from our remaining coal generation. We need policies that support coal operations which reduce emissions and offer investment recovery for the remaining value of coal plants which retire early. We also need help to minimize the impact on communities that depend on these plants.

All of these resources belong to the larger energy grid, which is enabling our carbon transition. As stewards of the grid, utilities own, operate and maintain this asset; raise and deploy capital to finance its growth and operation; and work with regulators to manage the risks associated with investments made on behalf of customers. Regulatory policy should ensure utilities continue to perform these critical functions to maintain the reliability, security and resilience of the energy grid during this transition.

Availability of Cost-effective, Carbon-free, Dispatchable Technologies

New cost-effective technologies have enabled our company and industry's progress in transitioning the nation's generating fleet and reducing carbon emissions. For at least the next decade, existing wind, solar, battery and natural gas technologies will continue to serve a growing portion of our energy needs while reducing carbon emissions and saving our customers money.

However, renewable generation and storage alone face significant technical and economic challenges if relied on exclusively to achieve carbon-free electricity. For example, the relatively short duration energy storage available today and anticipated in the future does not address seasonal challenges that arise when a system dependent on renewable resources experiences several days or weeks with low wind or solar generation. Even with continually declining prices, variable wind and solar resources are expected to provide diminishing value at high saturations. Fully relying on renewable sources could result in a costly overbuilding of the system where each incremental megawatt provides less capacity value, renewable curtailments reach high levels and massive investments in transmission and storage are required.

We need a suite of new, carbon-free resources that can be dispatched to complement our continued adoption of renewable energy, energy efficiency and demand response. Our research shows that these new resources will be the key to achieving a carbon-free generation fleet without a costly overbuilding of the energy grid. Others studying this issue have reached similar conclusions, including the MIT Energy Initiative, Energy+Environmental Economics and Vibrant Clean Energy.[18] These technologies may include carbon capture and storage, power to gas, seasonal energy storage, advanced nuclear or small modular reactors, deep rock geothermal and others not yet imagined.

Each of these options holds promise, but they will require considerable investment and further research and demonstration to become viable solutions at the cost and scale at which the electric sector will need them. Federal and state policies must support this development. We can also send clear signals to the market around price, capabilities and timing for when these technologies will be needed. In this way, utility resource plans provide the market signal — the "technology pull" — from which the private sector and national laboratories and federal agencies can align their investments, research and assets.

Conclusion

The finish line is clear — we aim to serve all customers by 2050 with carbon-free electricity. Through our analysis with the University of Denver, we are confident that both our interim and 2050 goal are the right goals for our customers but also to help limit warming to 2 C and possibly even 1.5 C.

Our vision is just the start. We will begin work now even though 2050 is decades away. Today, the technology and market exists to reach our interim goal and reduce carbon emissions 80 percent by 2030, but significant changes are needed to achieve reliable, affordable carbon-free electricity to serve our customers. We look to our partners to help us drive the advancements in technology and constructive policy to make it happen. While there may be differences of opinion around the details of how we get there, we are all in the same race together to reduce and eventually eliminate carbon.

Reducing carbon emissions should be the ultimate and shared objective. We must remain focused on this outcome and the drivers that will get us there as efficiently and cost effectively as possible.

As we work to make this vision possible, we will position our company and customers for success in a low-carbon future and provide greater long-term value for all stakeholders. We believe we can manage both the risks and capture the opportunities presented by this transition, and in the end, provide what our customers and other stakeholders want and need from us.

We are optimistic that through collaboration and with ingenuity and innovation, we will realize our vision for a carbon-free energy future.

APPENDIX F1 – LOAD AND DISTRIBUTED ENERGY RESOURCE FORECASTING

I. LOAD FORECAST METHODOLOGY

This Appendix discusses the methodology we used in conjunction with this Resource Plan to forecast customer need, including the requirements specified in Minn. R. 7610.0320. We also note that, while this Appendix documents our load and energy demand forecasting process, we have taken additional steps with respect to the treatment of energy efficiency (EE) forecasting in this Resource Plan, to model it as a supply-side resource. Where relevant, we include explanations of these steps in order to provide transparency, and explain how this base forecast correlates to the load and energy demand forecasting discussed in Chapter 3: Minimum System Needs, and Appendix F2: Strategist Modeling Assumptions and Inputs.

The Company relies on econometric models and other statistical techniques to develop the sales forecast. The econometric models relate our historical electric sales to demographic, economic and weather variables. We develop sales forecasts for each major customer class, in each state of our service area. The individual class forecasts for each state are summed to derive a total system sales forecast.

We convert the sales forecast into energy requirements at the generator level by adding energy losses. The forecasted losses are based on forecasted loss factors, which are developed using actual historical loss factors and are held constant over the forecast period. We develop the peak demand forecast using a regression model that relates historical monthly base peak demand to energy requirements and weather. The median energy requirements forecast and normal peak-producing weather are used in the model to create the median base peak demand forecast. We provide a detailed discussion of the forecast methodology later in this Appendix.

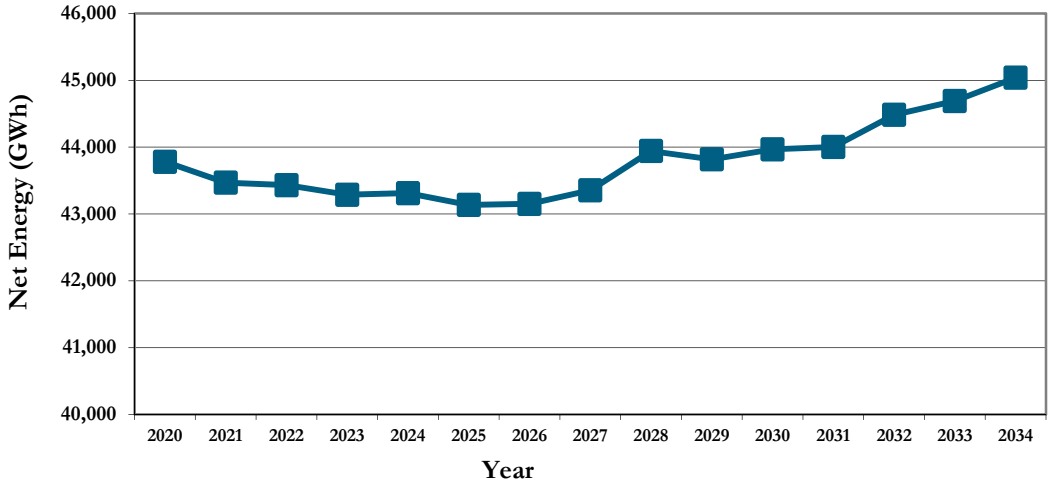
The forecasts are based on projections of economic activity for our various service areas provided by IHS Global Insight, Inc. (Global Insight). Global Insight projects continued growth in key economic indicators. For example, for the Minneapolis-St. Paul metropolitan area, households are expected to increase at an average annual rate of 0.8 percent during the 2020-2034 planning period. Real personal income is expected to increase 0.8 percent per year on average, and employment is expected to gain an average of 0.2 percent per year. Minnesota real gross state product is expected to increase at an average annual rate of 1.8 percent.

A. Energy Forecast

1. Base Forecast Methodology

The base energy forecast increases at an average annual growth rate of 0.2 percent over the 2020 – 2034 planning period, net of the 1.5 percent energy savings level approved in the Company's last Resource Plan, forecasted distributed solar, and electric vehicle charging projections. Electric energy requirements are expected to increase at an annual average of 90 gigawatt-hours (GWh), starting with 43,781 GWh in 2020 to 45,038 GWh in 2034. See Figure 1 below.

Figure 1: NSP System Total Median Net Energy (GWh)
(Includes 1.5 Percent EE Adjustment)



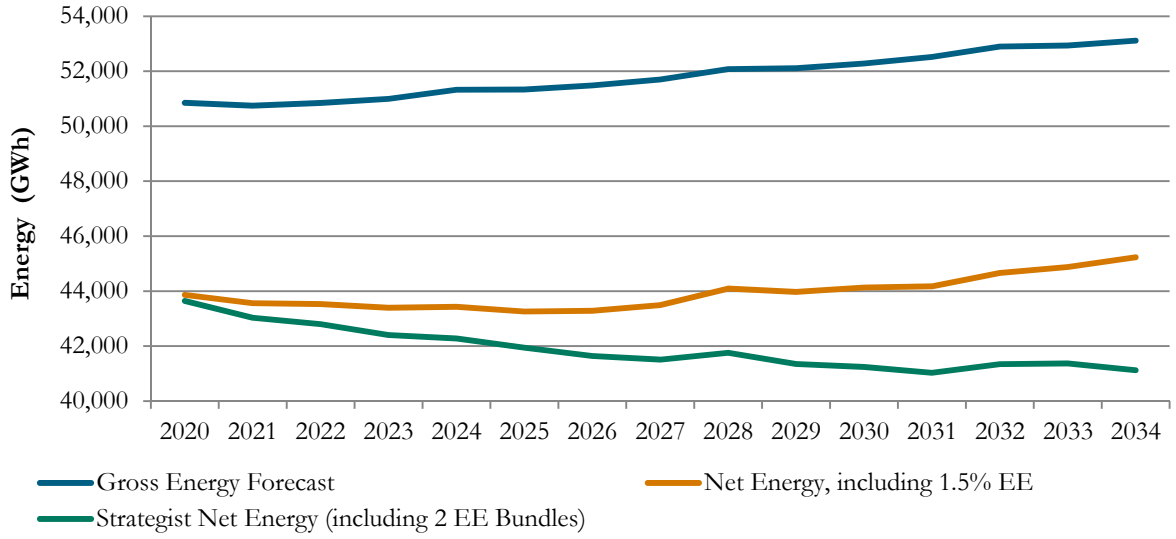
The projected 0.2 percent average annual growth in electric energy requirements is stronger than the actual growth seen over the past few years. After adjusting for unusual weather, electric energy requirements decreased at an average annual rate of *negative* 0.3 percent from 2014 to 2017.

2. Modifications for Use in Strategist

As noted in Chapter 3: Minimum System Needs, we undertook additional steps to allow EE to be modeled as a supply-side resource. This required that we adjust the base energy forecast (discussed in Part 1 above) to remove the embedded EE adjustment that projects the effects of 1.5 percent energy savings to the end of the Planning Period. This resulted in an NSP System Gross Energy Requirements forecast. In a separate process, we formulated annual EE savings amounts into

"Bundles" that we made available in the Strategist model along with other supply-side resources used to model EE as a supply-side resource in Strategist. We show these adjustments in Figure 2 below.

Figure 2: Gross Energy Requirements Forecast Compared to Net Energy Requirements Forecast



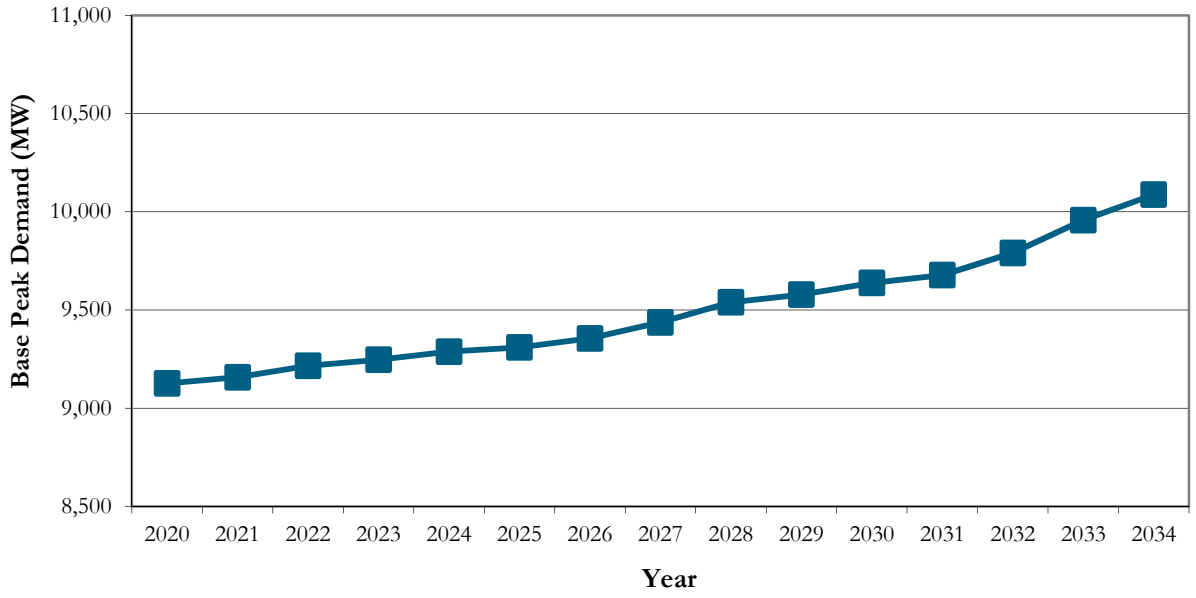
We discuss the EE Bundle modeling further in Appendix F2: Strategist Modeling and Appendix F6: Resource Options.

B. System Peak Demand Forecast

1. Base Forecast Methodology

During the 2020 – 2034 planning period, the median base peak increases at an average annual growth rate of 0.7 percent. As demonstrated in Figure 3 below, annual peak demand increases at an average of 69 MW each year, starting with 9,126 MW in 2020 to 10,087 MW in 2034.

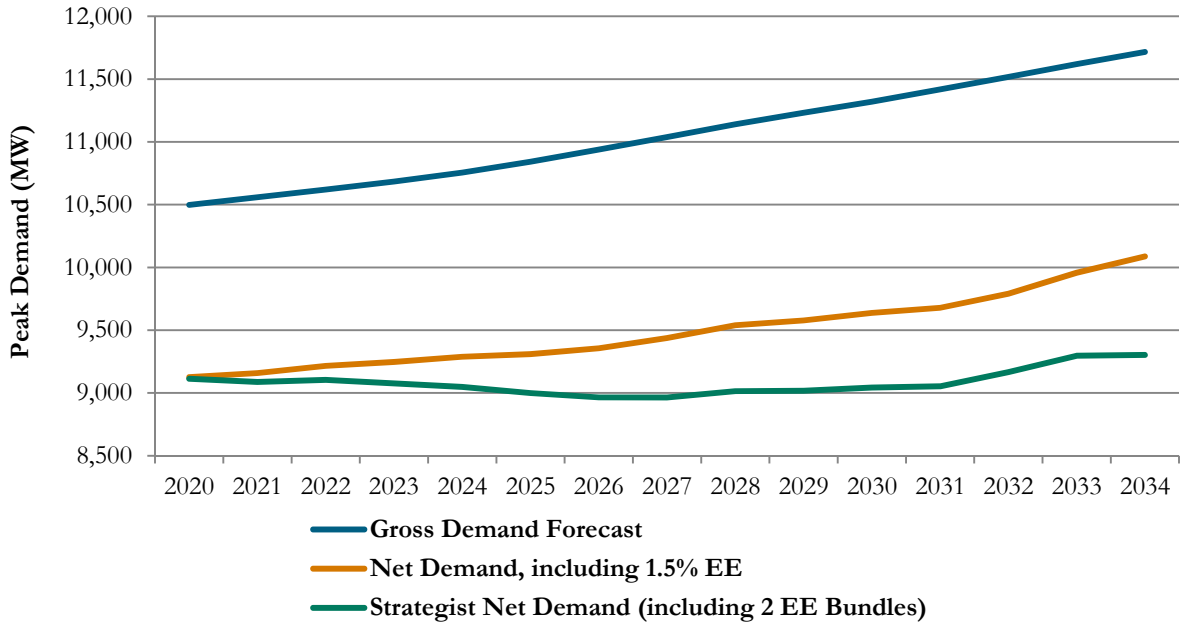
Figure 3: NSP System Median Base Summer Peak Demand (MW)
(Includes 1.5 Percent EE Adjustment)



2. Modifications for Use in Strategist

For modeling demand levels in Strategist, we took the same approach as noted in reference to the energy forecasts. Again here, for Strategist modeling purposes, we start with the base forecast and remove 1.5 percent EE adjustment in order to reflect gross load. This process enables us to model the system considering EE as a supply-side resource.

Figure 4: Gross Peak Demand Forecast Compared to Net Peak Demand Forecast



The balance of this Appendix discusses the energy and peak load forecasting methodologies, assumptions, analytics, adjustments, etc. to derive the System Energy Forecast presented in Part A.1 and Figure 1 above and the System Base Peak Demand Forecast presented in Part B.1 and Figure 3.

C. Key Demand and Energy Forecast Variables

Below we discuss some of the key variables that are included in the 2019 Resource Plan forecasts.

1. Demographics

Demographic projections are essential to the development of the long-range forecasts. The consumption of electricity is closely correlated with demographic statistics. The number of residential customers, weather data and economic indicators are key variables in the residential energy sales forecast. Over 99 percent of the variability in historical electric residential customer counts in our service territory can be explained through an econometric model that contains either population or households as key drivers. The forecasts for population and households are provided by Global Insight.

We forecast an average annual growth rate for total residential customers on our system of 0.6 percent, with the addition of 10,246 residential customers on average per year from 2020 through 2034.

2. Economic Indicators

Xcel Energy uses estimates of key economic indicators to develop electric sales forecasts. These variables include gross state product, employment and real personal income. The variables used are specific to the jurisdiction and are statistically significant in the sales models for the residential and commercial and industrial customer classes. Growth in electric energy consumption in the residential and commercial and industrial sectors closely follows trends in economic activity. Global Insight provided the economic forecasts used in our regression models.

For the planning period, the economy is expected to continue to grow, resulting in growth in electric energy consumption.

3. Weather

The peak demand for electric power is heavily influenced by hot and humid weather. As the temperature and humidity rise, the demand for cooling rises steeply. Our approach to forecasting peak demand includes using a weather variable that consists of the mean of an index of heat and humidity referred to as the temperature humidity index (THI). Simply stated, the THI is an accurate measure of how hot it really feels when the effects of humidity are added to the high temperature.

We have tracked the THI at the time of the system peak demand over the past 20 years. Because of the 20 years of smoothing, the weather variable does not drastically affect our median forecasts; however, it becomes a key factor in assessing the potential peak demand if and when hot and humid weather extremes are encountered. Since Xcel Energy must have adequate generating resources available during hotter than normal circumstances, planning for the extreme is important.

D. Forecast Methodology

Xcel Energy serves customers in five jurisdictions in the upper Midwest: Minnesota, North Dakota, South Dakota, Wisconsin and Michigan. We develop a forecast for each major customer class and jurisdiction using a variety of statistical techniques.

We first develop our system sales forecasts by using a set of econometric models at

the jurisdictional level for the Residential and Small Commercial and Industrial sectors for all jurisdictions, the Large Commercial and Industrial sector for Minnesota, and the Minnesota Public Street and Highway Lighting and Public Authority sectors. These models relate our historical electric sales to demographic, economic and weather variables as detailed in the prior section of this document.

For the remaining customer classes, Large Commercial and Industrial, Public Street and Highway Lighting, and Public Authority in all states but Minnesota, and Interdepartmental, we use trend analysis and customer specific data. We compile our system sales by summing the individual forecasts for each sector in each jurisdiction.

Since some energy is lost, mostly in the form of heat created in transmission and distribution conductors, we use loss factors to convert the sales forecasts into energy production requirements at the generator. The forecasted loss factors are developed using actual historical loss factors and are held constant over the forecast period.

We have developed a regression model to relate Xcel Energy's historical uninterrupted monthly peak demand to energy requirements and weather at the time of the peak in the winter and summer seasons. The median energy requirements forecast (50/50 forecast) and normal peak-producing weather are used in the model to create the peak demand forecast. (*Note*: Section II of this Appendix contains a comprehensive summary of the regression modeling process utilized to develop the energy and demand forecasts.)

Once the NSP System peak demand forecast is complete, a forecast is developed for the NSP System demand coincident with the Midcontinent Independent System Operator (MISO) system peak demand. The coincident demand forecast is developed using a regression model that determines the relationship between the NSP System demand coincident with the MISO peak demand and the NSP System peak demand (not coincident with the MISO peak demand). MISO only requires an annual coincident demand forecast for the next planning year. The current resource plan forecast is for the NSP System demand coincident to the MISO annual peak demand during the 2019-20 planning year (June 2019 – May 2020).

E. Forecast Adjustments

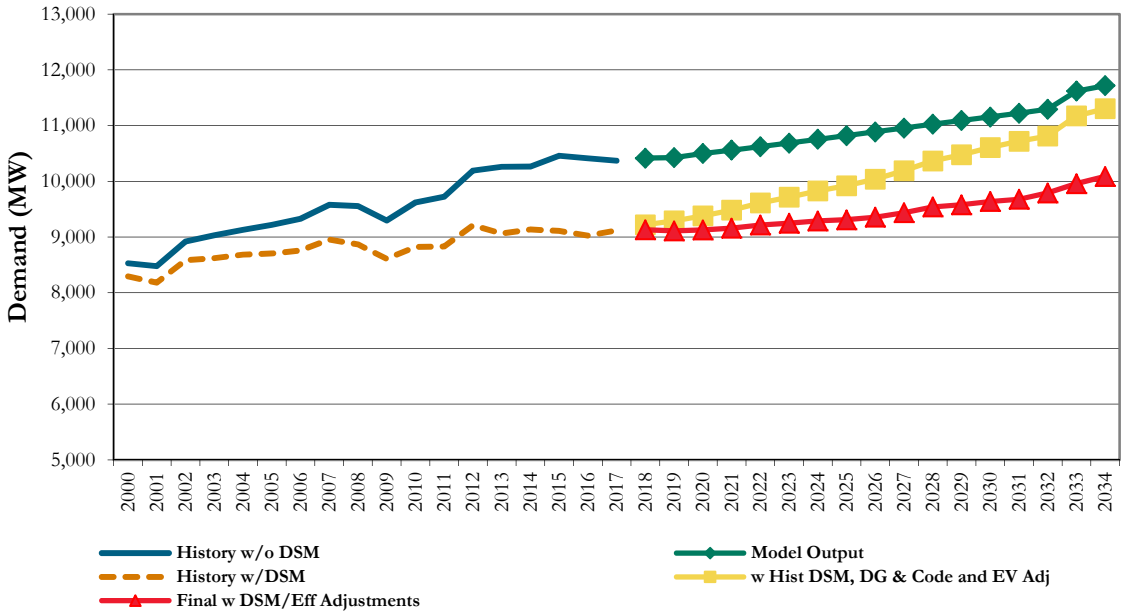
Our demand and energy forecasts are developed using a number of key forecast variables as described in this Appendix. One important adjustment to the forecasts is to take into account our conservation programs.

The EE methodology implemented for the State of Minnesota uses the same method for projecting the impacts of EE and its load management effects on the sales forecast as was used in our 2015 Resource Plan filing. There are three distinct steps to this process:

- Collect and calculate historical and current effects of EE on observed sales
- Project the forecast using observed data with the impact of EE removed (i.e. increase historical sales to show hypothetical case without EE)
- Adjust the forecast to show the impact of all planned EE in future years.
- Also adjust the forecast to account for codes and standards changes resulting in decreased sales that are in addition to Company-sponsored EE.

These EE adjustments are based on the Company's current Triennial Plan goals, which were based on the savings level approved in the resource planning process. The Commission approved an average annual energy savings level of 444 GWh for all planning years in our 2015 Resource Plan in Docket No. E002/RP-15-21.[1] Figure 5 below graphically illustrates the EE adjustment.

Figure 5: Illustration of EE Adjustment – NSP System Demand (MW)



For the State of South Dakota, the impacts from all conservation program

[1] *See* Order, Ordering Point No. 11 (January 11, 2017).

installations prior to 2018 are assumed embedded in the historical demand and energy data at a rate equal to the annual program installations from 2013 through 2017. To accurately predict future supply needs, the energy and demand forecasts must be reduced by an estimate of the incremental future conservation savings. For the base forecast, we adjust the demand and energy forecast by assuming all future annual conservation achievement equal to achievement of our 2018 goal as approved in the 2016 South Dakota DSM Status Report and 2018 DSM Plan filing (Docket No. EL17-019).

In response to the establishment of a Solar Energy Standard (SES) by the Minnesota Legislature, an increased emphasis has been placed on distributed solar generation. We developed a forecast of the expected impact on demand and energy based on new programs designed to meet goals established for the SES. We adjusted the Minnesota class-level sales forecasts and the system peak demand forecast to account for the impacts of customer-sited behind-the-meter solar installations on the NSP System. We discuss the distributed solar forecast methodology below.

After determining the base forecast, we develop net forecasts that include all adjustments, including future EE, distributed solar generation, electric vehicle charging, and the effects of our EE programs over time.

F. Additional Forecast Adjustments

We made additional adjustments to the energy and demand forecasts to account for expected changes in specific large customers' electricity usage. These additional adjustments include:

- Customers adding self-generation combined heat and power capabilities, which reduce energy consumption and peak demand,
- Increases or reductions in usage due to new customers in our service territory, or planned expansions or reductions of load by existing customers, and increasing use of plug-in electric vehicle charging, which we discuss in Part II.D below.

G. Forecast Variability

As with any forecast, our forecasts of energy requirements and peak demand depend on other forecasts of key variables. Changes in these variables will affect our forecasts. For instance, if the number of households in our service territory is lower than Global Insight has predicted, electric consumption in the residential sector will

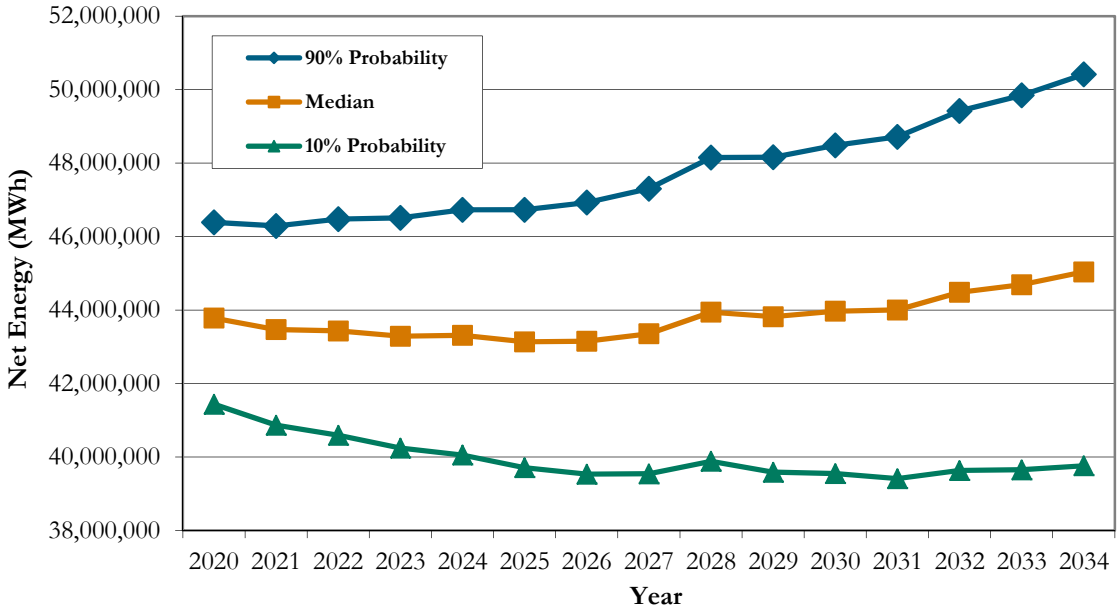
be lower. The peak demand for electric power each year is very sensitive to weather conditions and can vary considerably as the result of abnormal weather conditions.

Other forecast uncertainties include potential increases in loads due to new customers and potential losses in loads due to changes in customers' operations. For example, the potential exists for large increases in loads in the middle of the planning period due to increased mining activities in Northern Wisconsin. However, at this time there is still uncertainty around this potential increase and, therefore, we have not made an adjustment to the forecast.

Given that there is uncertainty in any long-term forecast, we supplement the median forecasts with forecasts developed using statistical techniques to reflect the potential variability in energy requirements and peak demand. These probability distributions were developed using a Monte Carlo stochastic simulation of peak demand (MW) and a simulation of energy (MWh). For example, the peak demand simulation involved taking 10,000 random draws from the weather probability distributions as well as 10,000 random draws from the 12-month sum of the energy probability distribution. The random draws produce 10,000 forecasts of peak demand and thus generate a probability distribution around the mean peak demand. We provide a more detailed description of the probability distribution methodology in Section II, and discuss summary results below.

The probability distributions developed for this forecast yielded a 90 percent probability that the net energy will be less than 50,416,762 MWh in 2034 – or alternatively, there is a 10 percent probability that the net energy will be less than 39,760,413 MWh. See Figure 6 below.

Figure 6: NSP System Total Net Energy (MWh)
(Includes 1.5 Percent EE Adjustment)



Figures 7 and 8 below show the higher and lower variations of the 2020 to 2034 long-range forecasts of base and net summer peak demand. [2]

[2] Where net summer peak demand includes adjustments form the base forecast to account for interruptible load.

H. Forecast Vintage Comparison

As described above, projections of energy and demand are fundamental to identifying the need for resources to meet expected customer needs. Thus, these forecasts are an important component in determining the size, type and timing of new generation resources. As a result, ensuring robust forecasts with fully analyzed assumptions and variables is a key component to supporting a Resource Plan or resource acquisition.

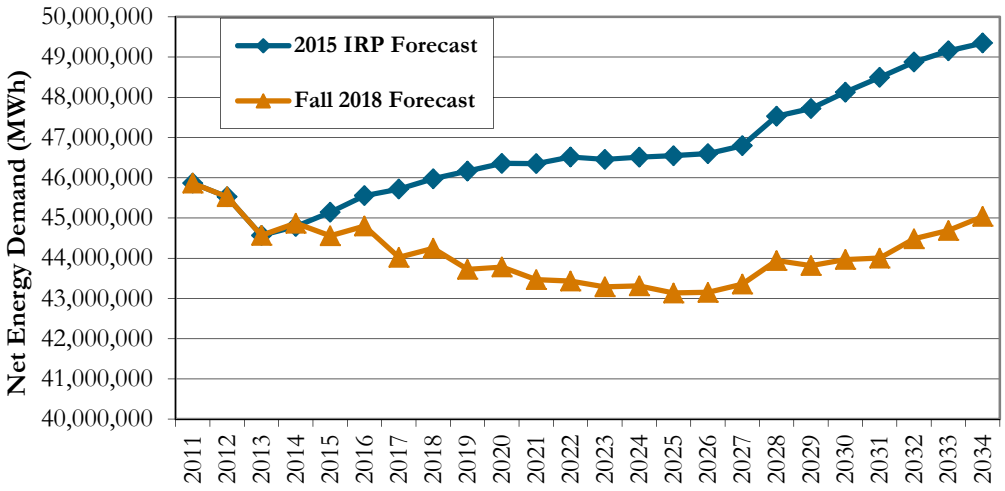
1. Forecast Vintage and Comparison

The review process for a Resource Plan or a resource acquisition typically takes a significant amount of time and effort to complete. During this time, forecasts can change as economic conditions, business operations, and technology changes occur. The graphs below compare the peak demand and energy of the Company's current forecast with the forecasts filed 2015 Resource Plan.

Figure 9 below indicates that the Fall 2018 energy forecast is lower than the Fall 2014 forecast provided in our 2015 Resource Plan due to lower and declining actual sales in 2015, 2016, and 2017. In particular, 2015-2017 weather normalized actual sales were lower for the NSPM residential sector and the NSPM small and large commercial and industrial sectors. In the residential sector, while the actual number of customers was slightly higher than estimated in the Fall 2014 forecast, the larger driver of the weaker-than-expected sales was lower use per customer. The NSPM small commercial and

industrial sector also experienced lower-than expected use per customer. The NSPM large commercial and industrial sector was projected to grow in the Fall 2014 forecast, but actual sales declined due to customers installing combined heat and power plants and loss of other load to locations outside Xcel's service territory.

Figure 9: Net Energy Requirements (MWh) – Comparison of Current and Previous Energy Forecast
Median (50th Percentile) Forecast



In addition, the projected rate of growth of key economic indicators is lower now than when the Fall 2014 forecast was produced. For example, the average annual growth rate during the planning period for Minnesota real personal income is 1.8 percent, compared to a projected 3.6 percent in the Fall 2014 forecast. As another example, the average annual growth rate during the planning period for Minneapolis-St. Paul total employment is 0.4 percent, compared to the projected 1.1 percent in the Fall 2014 forecast.

Figure 10 below shows a comparison of the base peak demand forecast to the Fall 2014 forecast. Similar to the energy forecast, the current demand forecast is lower than the Fall 2014 forecast underlying the 2015 Resource Plan for most of the planning period. While actual sales from 2011 to 2017 have trended downward, the NSP system peak demand has remained fairly flat, but well below the Fall 2014 forecast. The current forecast calls for peak demand to increase and surpass the Fall 2014 forecast as energy gains turn positive in the outer years of the planning period.

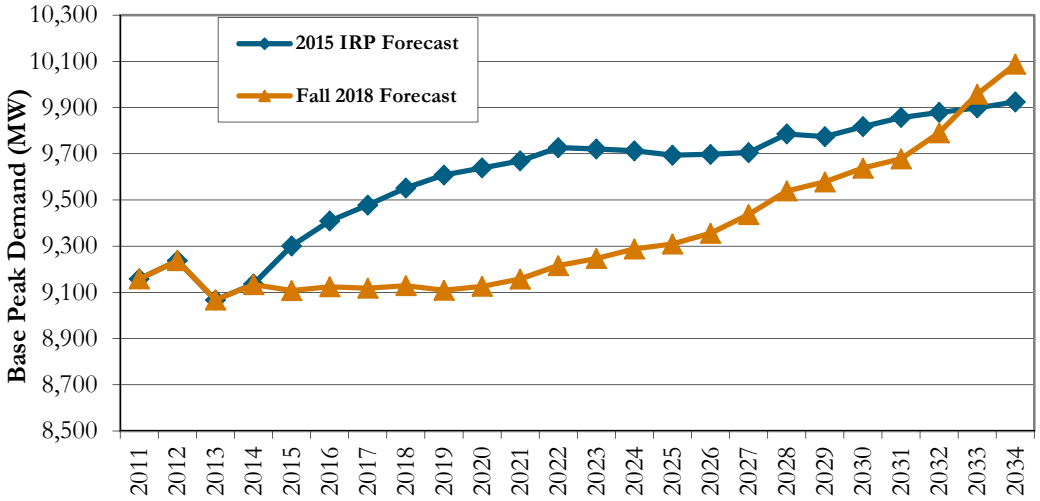
Median (50th Percentile) Forecast



II. OVERALL METHODOLOGICAL FRAMEWORK

In this Section, we outline the technical details regarding our forecast, consistent with the requirements of Minn. R. 7610.0320.

Xcel Energy prepares its forecast by major customer class and jurisdiction, using a variety of statistical and econometric techniques. The NSP System serves five jurisdictions: Minnesota, North Dakota and South Dakota are served by Northern States Power Company, a Minnesota corporation (NSPM); Wisconsin and Michigan are served by Northern States Power Company, a Wisconsin corporation (NSPW). The overall methodological framework is "model oriented." The NSPM and NSPW Systems operate as an integrated NSP System. The forecast is referred to as the 2018v2.1 Forecast (August 2018).

A. Specific Analytical Techniques

1. Econometric Analysis

Xcel Energy uses econometric analysis to develop jurisdictional MWh sales forecasts at the customer meter for the following sectors:

a) Residential without Space Heating;
b) Residential with Space Heating;

c) Small Commercial and Industrial;
d) Large Commercial and Industrial (Minnesota);
e) Public Street and Highway Lighting (Minnesota);
f) Other Sales to Public Authorities (Minnesota).

Xcel Energy also uses econometric analysis to develop the total system MW peak demand forecast.

2. Trend Analysis

Trend analysis is used for the "Other" sectors, which include Public Street and Highway Lighting (all states except Minnesota), Other Sales to Public Authorities (Michigan, North Dakota and Wisconsin), Interdepartmental sales (Michigan, Minnesota and Wisconsin), and Large Commercial and Industrial (Michigan, North Dakota, South Dakota, and Wisconsin).

3. Loss Factor Methodology

Loss factors by jurisdiction are used to convert the sales forecasts into system energy requirements (at the generator).

4. Judgment

Whenever possible, Xcel Energy uses quantitative models to structure its judgment in the forecasting process. However, judgment is inherent to the development of any forecast. The sales forecasts are estimates of MWh levels measured at the customer meter. They do not include line or other losses. The various jurisdictional class forecasts are summed to yield the total system sales forecast. Native energy requirements are measured at the generator and include line and other losses. Xcel Energy creates native energy requirements based on the sales forecasts.

A system loss factor for each jurisdiction, developed based on average historical losses, is applied to the jurisdictional sales forecast to calculate total losses. The sum of the jurisdictional MWh sales and losses equals native energy requirements. The native energy requirements, along with peak producing weather and binary variables, are then used as independent variables within an econometric model to forecast MW peak demand for the NSP System.

B. Models Used

1. Residential Econometric Models

Sales to the residential sectors represent 29.7 percent of total NSP System electric retail sales in 2018. Residential sales are divided into with space heating and without space heating customer classes for each jurisdiction. Regression models using historical data are developed for each residential sector. A variety of independent variables is used in the models, including:

- Number of customers;
- Real Personal Income for respective jurisdiction;
- Employment for the respective jurisdiction;
- Gross State Product for respective jurisdiction;
- Actual heating and temperature humidity index (THI) degree days;
- Number of monthly billing days.

2. Small Commercial and Industrial Econometric Models

The small commercial and industrial sector represents 43.7 percent of NSP System electric retail sales in 2018. The models are regressions using historical data. The models include a combination of variables, including the following:

- Number of small commercial and industrial customers;
- Gross State or Metro Product for respective jurisdiction;
- Employment for respective jurisdiction;
- Real Personal Income for respective jurisdiction;
- Actual heating and temperature humidity index (THI) degree days;

3. Large Commercial and Industrial Econometric Models

Sales to the large commercial and industrial sector represent 26.0 percent of NSP System electric retail sales in 2018. The models are regressions using historical data and a combination of variables, including the following:

- Industrial Production for respective jurisdiction;
- Number of monthly billing days;
- Indicator variables such as CI reclassification.

4. Others

Sales to the "Others" sector represent 0.6 percent of NSP System electric retail sales

in 2018. This sector includes Public Street and Highway Lighting (PSHL), Sales to Public Authorities (OSPA) and Interdepartmental (IDS) sales. Because this class represents a very small portion of the total sales, trend analysis is used and very little growth is forecast. Exceptions to this are the Minnesota Street Lighting and Other Public Authority classes. Minnesota Street Lighting sales are based on population in the Minneapolis-St. Paul MSA. Minnesota Other Public Authority sales are based on the Minnesota Other Public Authority customer forecast.

5. Peak Demand Model

An econometric model is developed to forecast base peak demand for the entire planning period. The model includes a combination of variables, including the following:

- Weather normalized native energy requirements
- Peak producing weather by month
- Binary variables

C. Methodology Strengths and Weaknesses

The strength of the process Xcel Energy uses for this forecast is the richness of the information obtained during the analysis. Xcel Energy's econometric forecasting models are based on sound economic and statistical theory. Historical modeling and forecast drivers are based on economic and demographic variables that are easily measured and analyzed. The use of models by class and jurisdiction gives greater insight into how the NSP System is growing, thereby providing better information for decisions to be made in the areas of generation, transmission, marketing, conservation, and load management.

With respect to accuracy, forecasts of this duration are inherently uncertain. Planners and decision makers must be keenly aware of the inherent risk that accompanies long-term forecasts. They must also develop plans that are robust over a wide range of future outcomes.

D. Data Definitions

The following is a list of definitions of the variables considered in Xcel Energy's econometric models.

Table 4: Jurisdiction Abbreviations

Mi or MI	State of Michigan
M or MN	State of Minnesota
N or ND	State of North Dakota
S or SD	State of South Dakota
W or WI	State of Wisconsin

Table 5: Monthly MWh Sales Series

SLSReswo(Juris)	Residential without space heating for given jurisdiction
SLSResSH(Juris)	Residential with space heating for given jurisdiction
SLSSmCI(Juris)	Small commercial and industrial for given jurisdiction
SLSLgCI(Juris)	Large commercial and industrial for given jurisdiction

Table 6: Monthly Customer Series

CustReswo(Juris)	Residential without space heating for given jurisdiction
CustResSH(Juris)	Residential with space heating for given jurisdiction
CustSmCI(Juris)	Small commercial and industrial for given jurisdiction
CustLgCI(Juris)	Large commercial and industrial for given jurisdiction

Table 7: Monthly Economic and Demographic Series

HH_(Juris)	Number of Households in given jurisdiction
NR_(Juris)	Total Population in given jurisdiction
GMP_(MSA)	Gross Metro Product for given metropolitan statistical area
GSP_(State)	Gross State Product for given state
EE_(Juris)	Total Employment in given jurisdiction
IPMFG_(Juris)	Industrial Production Index - manufacturing in given jurisdiction
CYP_(Juris)	Real Personal Income in given jurisdiction
(Juris)TotRes_RAP	Real Average Price for electric sales to residential customers

Table 8: Monthly Data Variables used in Demand Model

THI12(Month)Cust	Temperature Humidity Index @12:00 noon on the peak day multiplied by total retail customers
THI15(Month)Cust	Temperature Humidity Index @3:00 PM on the peak day multiplied by total retail customers.
HDD(Season)	Normal Heating Degree Days on the day of the Peak multiplied by a binary variable for the season (winter - Wtr, shoulder month - sh)
WNActEnergy_LpYrAdj_12MoSum	12 month rolling sum of the weather normalized net energy requirements adjusted to remove the effect of leap years

Table 9: Monthly Weather Variables used in Sales Models

H65_bill (Juris)(Month)	HDD base 65 for given jurisdiction and month
T65_bill(Juris)(Month)	THI DD base 65 for given jurisdiction and month

Table 10: Other Monthly Variables

BillDaysCellnet21	Billing Month Days

Table 11: Monthly Binary Variables

Jan	Binary variable for the month of January
Feb	Binary variable for the month of February
Mar	Binary variable for the month of March
Apr	Binary variable for the month of April
May	Binary variable for the month of May
Jun	Binary variable for the month of June
Jul	Binary variable for the month of July
Aug	Binary variable for the month of August
Sep	Binary variable for the month of September
Oct	Binary variable for the month of October
Nov	Binary variable for the month of November
Dec	Binary variable for the month of December

E. Data Sources

MWh sales and MW peak demand. Xcel Energy uses internal and external data to create its MWh sales and MW peak demand forecast.

Historical MWh sales. Historical MWh sales are taken from Xcel Energy's internal company records, fed by its billing system. Historical coincident net peak demand

data is obtained through company records. The load management estimate is added to the net peak demand to derive the base peak demand.

Weather data. Weather data (dry bulb temperature and dew points) were collected from www.weatherunderground.com and the National Oceanic and Atmospheric Administration for the Minneapolis/St. Paul, Fargo, Sioux Falls, and Eau Claire areas. The heating degree-days and THI degree-days are calculated internally based on this weather data.

Economic and demographic data. Economic and demographic data is obtained from the Bureau of Labor Statistics, U.S. Department of Commerce, and the Bureau of Economic Analysis. Typically they are accessed from IHS Global Insight, Inc. data banks, and reflect the most recent values of those series at the time of modeling.

F. Energy Efficiency Programs

The regression model results for the residential classes and commercial and industrial classes are reduced to account for the expected impacts of energy efficiency programs.

The EE methodology implemented for the State of Minnesota utilizes a transparent method to project the impacts of energy efficiency (including the energy savings impacts from our current demand response programs) in sales forecasts. There are three distinct steps to this process:

- Collect and calculate historical and current effects of EE on observed sales
- Project the forecast using observed data with the impact of EE removed (i.e. increase historical sales to show hypothetical case without EE)
- Adjust the forecast to show the impact of all planned EE in future years.

The first step involves collecting data involving any measure that would cause an impact on the time period utilized in the sales forecast. In this model, we use the time period from 2003 to 2017, and therefore the historical EE would include any measure that results in decreased sales in any (or all) years from 2003 through 2017.

Since the vast majority of EE measures have a lifetime greater than one year (exceptions include but are not limited to behavioral energy savings programs), the impact on sales will include the year that a measure is installed as well as any years that follow until the measure has reached the end of its useful life. For example, a residential lighting measure that was installed in 2008 and has a life of six years will result in a sales reduction from 2008 to 2013 (six full calendar years). Though a measure may be installed in June of 2008 and, thus, would persist until May of 2013,

the Company believes that the simplifying case in which all measures are installed for the entire calendar year is sufficient.

Due to the wide variation of measures available to customers, the Company sums the savings for each year by EE program to optimize the level of detail and depth of history included in the model. As a result of limitations in the quality of data prior to 1996, the Company has taken the conservative approach and omitted the impacts of achievements before 1996. While this may seem inconsequential, some programs have a 20-year lifetime, and EE from 1998 could therefore affect the 2017 usage. Achievement data are from the approved Conservation Improvement Program (CIP) Status Reports filed annually for each year since 1996.

Once the total impact of EE in effect is calculated for each year, a hypothetical sales data set is created. This series consists of the observed sales from 2003 through May 2017 plus the effective EE calculated for all EE measures installed in that year as well is achieved savings from programs in prior years that are still within the useful measure life.

The hypothetical sales data is used to generate a sales forecast that has entirely excluded the impacts of company-sponsored EE. It is important to note that customer-initiated EE or EE due to codes and standards (naturally-occurring EE) is not calculated as part of the CIP.

Once the sales forecast based on hypothetical sales has been generated, the Company subtracts the projected future EE from the total to determine the EE-adjusted sales. In addition, codes and standards changes resulting in decreased sales not documented within CIP may have separate adjustment factors applied in addition to the company-sponsored EE. The source for company-sponsored EE adjustments will be based on the CIP Plan in effect at the time of the forecast.

Exogenous adjustments were made to the Minnesota sales model output for future years to account for codes and standards changes for lighting in the Residential and Business segments. These adjustments are in addition to the adjustments made for future EE program achievement. The sales model implicitly accounts for some portion of changes in customer use, due to conservation and other influences, by basing projections of future consumption on past customer class energy consumption patterns. However, when technologies driving code and standard changes are adopted at an accelerated pace but can no longer be incentivized through EE programs, the sales forecast is not able to adequately adapt to future changes due to the difference between past and projected customer use, and the future changes are

not accounted for in the exogenous adjustments made for EE program achievement.

As a result of recent changes in business and residential lighting practices, two new additional adjustments have been added to the sales forecast. The first is for residential customers only, and takes into account the new standard efficiency for general service lamps (also known as EISA standards). For the adjustment to the sales forecast, this only calculates the difference between a standard incandescent and an EISA-compliant halogen bulb, since additional efficiency will still be captured through EE programs. The second adjustment projects business class sales reductions resulting from accelerated technological improvements in the business lighting sector due to improvements in solid state lighting (LED).

A monthly forecast of the impact of new EE programs is developed by Xcel Energy's DSM Regulatory Strategy and Planning Department, and is used to reduce the class level sales forecasts that result from the regression modeling process. Impacts from all program installations through 2017 are assumed to be imbedded in the historical data, so only new program installations are included in the EE adjustment.

The Company's demand response programs result in short-term interruptions of service designed to reduce system capacity requirements rather than permanent reductions in energy use, so it is not considered here.

G. Behind-the-Meter Distributed Solar Generation

In response to the establishment of a Solar Energy Standard (SES) by the Minnesota Legislature an increased emphasis has been placed on distributed solar generation. A forecast of the expected impact on demand and energy has been developed based on new programs designed to meet goals established for the SES. The process of incorporating behind-the-meter distributed solar generation into the forecast process is similar to how EE program savings are incorporated in the sales and peak demand forecasts. Historical behind-the-meter distributed solar generation is added-back to the historical sales and peak demand modeling data, similar to how historical company-sponsored EE programs savings are added back to the historical sale and peak demand modeling data. The forecast output, based on the hypothetical sales and peak demand data with behind-the-meter solar generation added back to the historical sales and peak demand data, is then reduced for the future impacts of behind-the-meter installations on the class level sales in Minnesota and South Dakota and the NSP System peak demand.

H. Forecast Adjustments

Adjustments have been made to the forecast to account for planned changes in production levels for several large customers in Minnesota and Wisconsin. The most significant of these changes is the reduction of sales and demand related to the scheduled installation of customer-owned Combined Heat and Power generating facilities in 2017 and 2018.

I. Overview of Probability Distributions

Xcel Energy uses a straightforward extension of the peak demand econometric model to assess risk around the expected value of the peak demand by conducting a Monte Carlo simulation on the main drivers of the peak model (weather and native energy requirements). For the Monte Carlo energy probability distribution model, the main drivers are weather, Minnesota Households (HH_MN), and Minnesota Real Gross State Product (CGSP_MN).

The Monte Carlo stochastic simulation of peak demand (MW) or energy (MWh) involves taking 10,000 random draws from the weather probability distributions as well as 10,000 draws from the 12-month sum of energy probability distribution (or HH_MN and CGSP_MN probability distributions), which, in turn, produces 10,000 forecasts of peak demand (or energy), and thus generates a probability distribution around the mean peak demand (or mean energy).

For example, if the econometric model forecasts that the mean peak demand for 2025 is 9,309 MW, then using the same econometric model, the Monte Carlo simulation method forecasts that there is a 90 percent probability that the 2025 peak demand will be less than 10,317 MW, or alternatively, a 10 percent chance that the peak will be less than 8,288 MW.

In summary, the Monte Carlo stochastic simulation method adequately captures the effect of extreme weather on monthly peak demand and monthly energy usage, while preserving the expected value or mean forecast of peak demand and energy.

J. Data Adjustments and Assumptions

Weather Adjustments. Xcel Energy adjusts the monthly weather data to reflect billing schedules. Therefore, the monthly weather data corresponds exactly with the billing month schedule.

Economic Adjustments. All Consumer Price Index data is deflated to 1982=1 and related economic series are deflated to 2009 constant dollars.

K. Assumptions and Special Information

The data used in Xcel Energy's forecasting process has already been discussed in a general way. Descriptions and citations of sources for the data sets have been mentioned within this documentation under different sections.

Xcel Energy believes that its process is a reasonable and workable one to use as a guide for its future energy and load requirements. The underlying assumptions used to prepare Xcel Energy's median forecast are as follows:

- *Demographic Assumption.* Population or household projections are essential in the development of the long-range forecast. The forecasts of customers are derived from population and household projections provided by IHS Global Insight, Inc., and reviewed by Xcel Energy staff. Xcel Energy customer growth mirrors demographic growth over the forecast period.
- *Weather Assumption.* Xcel Energy assumes "normal" weather in the forecast horizon. Normal weather is defined as the average weather pattern over the 20-year period from 1998-2017. The variability of weather is an important source of uncertainty. Xcel Energy's energy and peak demand forecasts are based on the assumption that the normal weather conditions will prevail in the forecast horizon. Weather-related demand uncertainties are not treated explicitly in this forecast.
- *Loss Factor Assumptions.* The loss factors are important to convert the sales forecast to energy requirements. Xcel Energy uses a historical average loss factor for each jurisdiction, and assumes it will not change in the future.

L. MISO Coincident Peak Demand Forecast

Once we complete the NSP System Peak Demand Forecast, we develop a forecast for the NSP System Peak Demand coincident with the MISO system peak. MISO has published the date and time of the MISO system peak for each of the four summer months (June – September) of 2005 – 2017. Company records were queried to determine the NSP System uninterrupted peak at the time of each of the MISO monthly peak days.

We then develop a forecast of the NSP System peak demand coincident with the MISO peak using a regression model based on the NSP System peaks coincident with

MISO, the NSP System peaks not coincident with MISO, and the weather variable representing the temperature-humidity index at 3:00 PM on the MISO coincident peak day for each summer month. MISO only requires an annual coincident peak forecast for the next planning year. The current forecast is for the NSP System peak coincident to the MISO annual peak during the 2019-20 planning year (June 2019 – May 2020).

M. Forecast Coordination

Xcel Energy reports its energy and peak demand forecasts to MISO, who then combines the forecasts of all its member utilities. Xcel Energy also reports its forecast to the Public Service Commission of Wisconsin as part of its Strategic Energy Assessment (SEA) process. In this process, the Wisconsin portion of the total Xcel Energy system load is combined with other Wisconsin electric utilities to form a statewide Wisconsin forecast.

III. DISTRIBUTED ENERGY RESOURCES FORECAST

A. Distributed Solar

We offer several programs to customers interested in solar as a renewable opportunity. Specifically we provide incentives under our Solar*Rewards program, and the opportunity to earn bill credits for community solar gardens in our Solar*Rewards Community program. In addition, we offer a net-metering option for customers installing incentivized small scale solar. We have factored all of these distributed solar PV options into our Reference Case, Medium, and High distributed solar forecast.[3] We note that the methodology used to forecast distributed solar for this Resource Plan is consistent with what we used in our November 2018 Integrated Distribution Plan, filed in Docket No. E999/CI-18-251.

1. Reference Case Assumptions

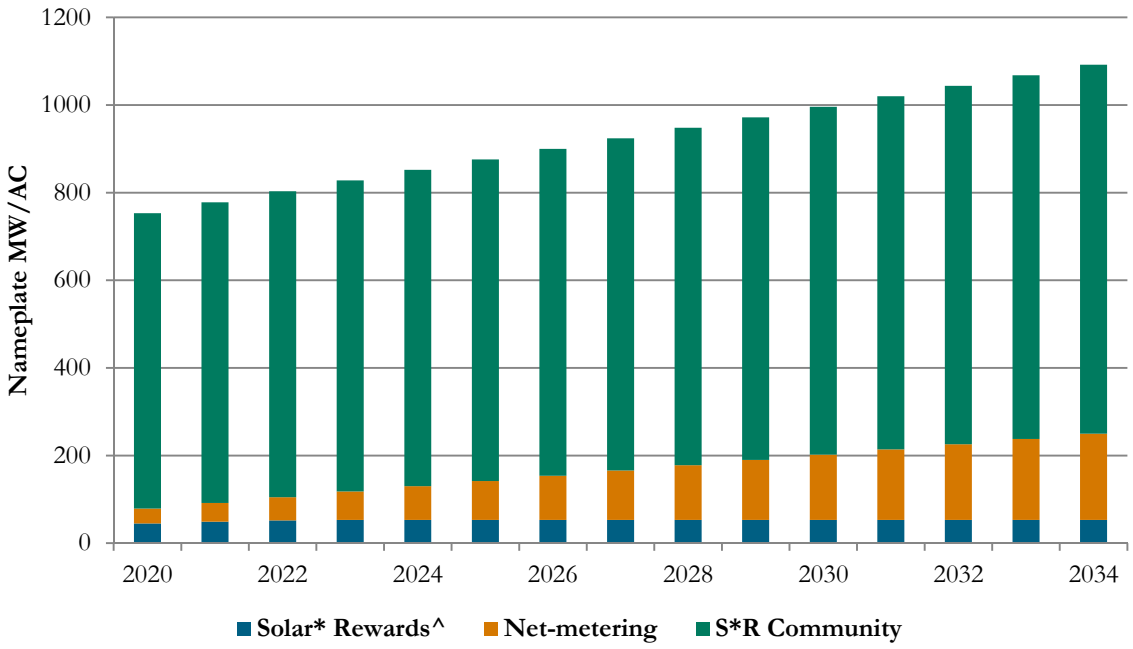
In determining our Reference Case, we updated our goals to be consistent with 2017 legislative outcomes that: (1) increased 2018-2020 Solar*Rewards incentive funding, (2) eliminated new Made in Minnesota awards after 2017, with final installations completed by October 2018, and 3) eliminated new Solar*Rewards systems after 2021, with final installations completed by 2023. We assumed net-metering only system additions would continue at current annual levels through 2021 and increase in 2022 to accommodate for demand from the elimination of the Solar*Rewards program in

[3] We note that we provide information specific to just Solar*Rewards Community as Appendix N8.

this scenario. We based attrition and completion lag rates on historical analysis of cancelled and completed projects, and applied these to program application forecasts to derive final installation estimates.

Due to the large response to our Solar*Rewards Community program, which has no statutory budget or capacity limit, we are forecasting additions of 673 MW through 2019 in this filing. For our Reference Case assumptions through the Resource Plan planning period, we assume Solar*Rewards Community adjusts to approximately 12 MW per year after 2021 to account for significant early adoption of CSGs and reduction in tax benefits. The graph below reflects the Reference Case forecast of distributed solar PV forecast.

Figure 11: Reference Case – NSP System Distributed Solar PV Forecast (Nameplate MW/AC)



^Includes Made in Minnesota

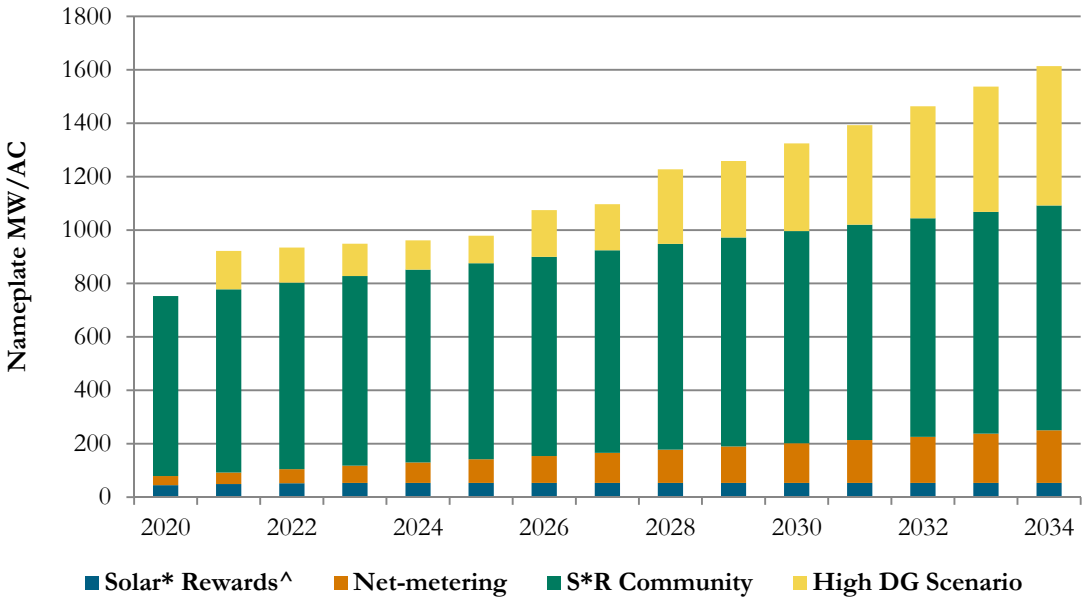
2. Reference vs High Forecasts

The Reference and High scenarios hold the levels of Solar*Rewards and Made in Minnesota constant for the reasons discussed above. For net metering and CSG, we assume that customers that participate in solar programs would consider, in the majority of cases, that these programs are substitutes for each. Therefore the incremental growth in one category is interchangeable with another category. For

example, we are estimating that total solar PV in 2034 is approximately 1,100 MW – of which, approximately 850 MW is net metering and CSG.

For the High scenario, we used a Payback adoption model with lower installation costs. We also applied a 10 percent reduction to the solar installation cost curve starting in 2020. Solar installation costs in the High scenario are set to be higher for the first year due to new import tariffs and contracts already in place. Hence, there is a low probability that the solar installation prices will drop significantly below the Reference scenario for 2019. The adoption of solar is flat in the early 2020s, because the decline in solar installation cost is offset by the decline in Investment Tax Credit (ITC). The Payback model results indicate around 1,600 MW for total installed distributed solar by 2034. The graph below reflects the high forecast of distributed solar PV forecast.

Figure 12: High Forecast Case – NSP System Distributed Solar PV Forecast (Nameplate MW/AC)



B. Distributed Wind

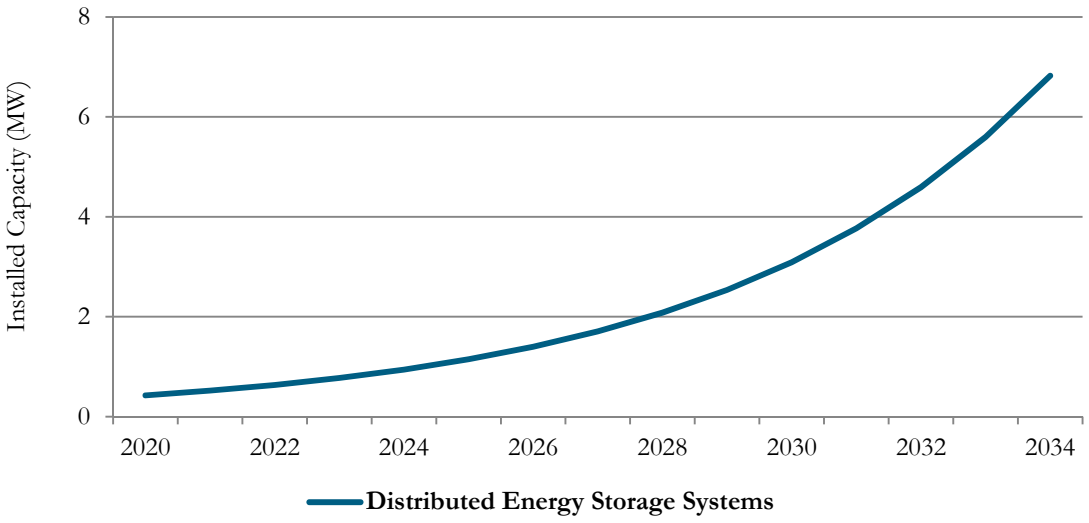
We presently have a small number of distributed wind projects on our system, with a total of 59 projects that comprise 14 MW. We believe distributed wind will continue to be a very small proportion of DER on our distribution system, largely due to the rapid development of solar and storage markets – and their relative ease of adoption, compared to wind. Additionally, there is little information available in the industry

regarding the adoption of distributed wind. For these reasons, we are not providing a forecast in conjunction with this Resource Plan.

C. Distributed Storage

Navigant Research's Global DER Overview, 2Q 2019, projects a growth rate of 21.9 percent for Distributed Energy Storage Systems (DESS). From 2017 through April 2019, we received approximately 50 interconnection applications for energy storage on our distribution system. Of these 50 applications, 32 are complete and in operation, comprising approximately 350 kW. Figure 13 below extrapolates the current installations at the Navigant projected rate of growth.

Figure 13: NSP System Distributed Energy Storage Systems Forecast



The impact of DESS is, currently, not incorporated into demand forecasting or as a specific supply side resource. We discuss the utility-scale storage as it applies to the modeling underlying this Resource Plan in Appendix F6: Resource Options.

D. Electric Vehicles

Our customers are procuring EVs in greater numbers than ever before. In our Upper Midwest service area, the total number of EVs is currently approximately 9,500.[4] Nationally, annual sales of EVs increased by 81 percent from 2017 to

[4] IHS Markit, 2019. The IHS Markit data is provided at the zip code level for zip codes within the Company's service territory. Utility jurisdictions do not exactly follow zip code boundaries, so there may be some margin

2018.[5] Forecasts suggest that we may see increased adoption as EVs are poised to grow into a more mainstream new vehicle option, with over 40 models of EVs available in the United States today. The nascent nature of this market however, makes the possibility of significantly more or less adoption a large variable, and thus difficult to forecast.

The approach we took in this Resource Plan to forecast EVs allows for consideration of a wide range of potential futures, and represents an advancement and change from our approach in our November 1, 2018 Integrated Distribution Plan (IDP). The IDP used a forecast based on national level adoption that had informed early- to mid-2018 filings in other dockets.[6] At that time we noted our intent to improve, benchmark, and validate our forecasting models and assumptions, which is underway. We also noted that we were doing work around electrification to support our upcoming Resource Plan.

That said, for the purposes of this Resource Plan, we made an exogenous adjustment for a base level of light duty electric vehicle adoption in both our energy and demand forecasts. We then worked with E3 to develop a high "electrification" load forecast sensitivity, which includes a broader range of EV adoption – as well as other electrification impacts.[7] This creates a wide band of possible outcomes to inform our modeling. We believe that by limiting the modeling of a highly dynamic external factor to a Base and High view, we are better able to examine the base needs of the system, while also considering the long-term impacts of potential high electrification across Minnesota's economy.

We illustrate the Base and High Electrification forecasts that informed this Resource Plan in Figure 14 below. We additionally show the Base EV forecast for this Resource Plan to give perspective on the magnitude of electrification the High Electrification sensitivity affords the modeling in this Plan.

---

of error in this value.

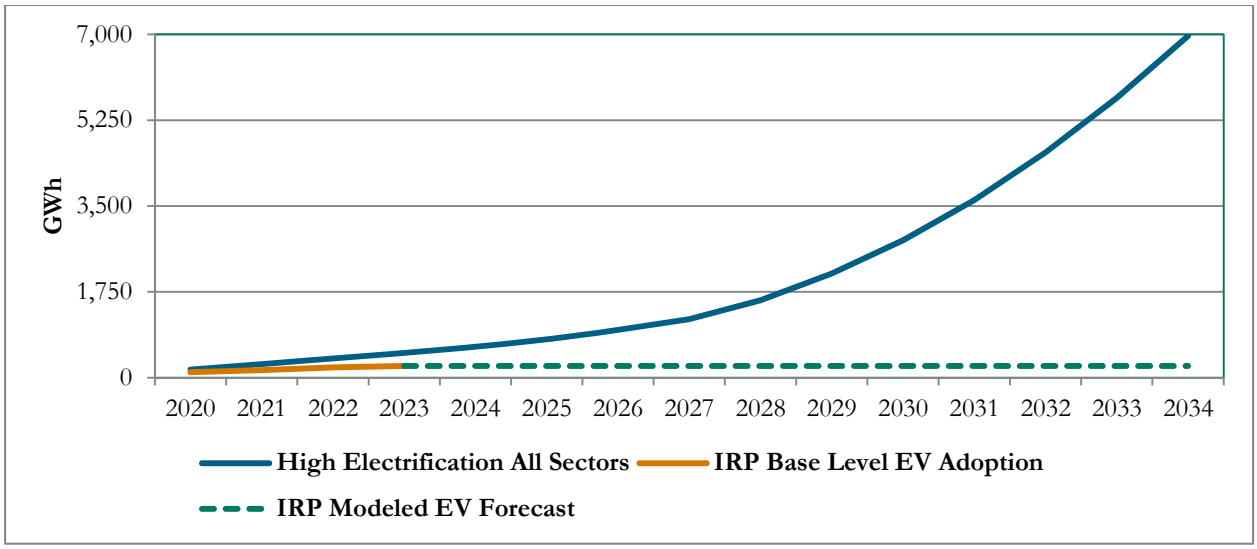
[6] June 1, 2018 filing in Docket No. E002/M-15-111 and a January 11, 2018 response to Minnesota Commission Staff Information Request No. 8 in our hosting capacity proceeding in Docket No. E002/M-17-777.

[7] We provide a full discussion of the E3 high electrification sensitivity as Appendix F4.

Figure 14: NSP System Base Level Compared to High Electrification Sensitivity – 2020-2034



We discuss our development of the Base Forecast below. We discuss the details of the High Electrification Sensitivity in Appendix F4: High Electrification Sensitivity and note that it was developed as part of E3's PATHWAYS study, provided as Appendix P3: Minnesota PATHWAYS Report June 2019 (E3).

1. Base EV Adoption

The Base EV forecast projects adoption of light duty vehicles in the first five-years of the planning period and then holds constant from year six through the remainder of the planning period. This Base level of light duty EV adoption is used in all modeling scenarios, and is consistent with the likely forecast from the IDP. The rate and level of EV adoption impacts the energy forecast, and customer charging behavior assumptions impact the demand forecast, which we discuss in turn below.

a. EV Adoption Levels

Our Base EV forecast is based on an internally-developed methodology that incorporates both economic payback and Bass diffusion (technology adoption) model.[8] Key variables informing our adoption estimates for the base energy forecast

[8] The Bass Model or Bass Diffusion Model was developed by Frank Bass. It consists of a simple differential equation that describes the process of how new products get adopted in a population. The model presents a rationale of how current adopters and potential adopters of a new product interact. The basic premise of the model is that adopters can be classified as innovators or as imitators and the speed and timing of adoption

include:

- Electricity Prices
- Vehicle Battery Prices
- Gasoline Prices
- Car ownership
- Car usage
- Efficiency

In addition to EV adoption, customer charging behavior is an important consideration to factor into our load forecasts. Because we are reflecting adoption of only light duty EVs in our base forecast, our primary considerations are the share of charging done at homes, and penetration of managed charging stations. Our source for this was the DOE EV Project Data Set.

Forecasting is very sensitive to various assumptions, especially for new technologies like EVs that are in early stages of adoption. Forecasts are also sensitive to several externalities like policy changes (such as incentives), technology changes (such as battery improvements and autonomous vehicles), geopolitical issues (such as trade and tariff issues), availability of raw materials (such as shortages of lithium or cobalt), etc. Additionally, many of the inputs change frequently and could produce significant swings in the model outputs.

2. *High Electrification Sensitivity*

We worked with E3 to develop a High Electrification load forecast sensitivity, derived from the E3 statewide decarbonization analysis using PATHWAYS,[9] which we ran for each Resource Plan modeling scenario. The objective of this sensitivity was to create a "bookend," examining the possible impacts on load growth and peak demand growth on our Upper Midwest NSP System service area, under a scenario with electrification sufficiently aggressive to achieve Minnesota's economy-wide goal of an 80 percent reduction in greenhouse gas (GHG) emissions below 2005 levels by 2050.[10]

---

depends on their degree of innovativeness and the degree of imitation among adopters. The Bass model has been widely used in forecasting, especially new products' sales forecasting and technology forecasting.

[9] In summary, for the PATHWAYS study, E3 developed a set of long-term economy-wide, deep decarbonization scenarios for the state of Minnesota. These scenarios provide an exploration of the cross-sectoral implications of meeting economy-wide carbon reduction goals, and highlight the role of Xcel Energy, and the electric sector as a whole, in meeting the state's economy-wide carbon goal. For details, see the E3 Minnesota PATHWAYS Report as Appendix P3.

[10] Minn. Stat. 216H.02, Subd. 1. *See* https://www.pca.state.mn.us/air/state-and-regional-initiatives.

Without suggesting this much electrification will or should occur, this sensitivity asks: If there were very aggressive electrification of transportation, buildings, and other end uses, what are the potential impacts on energy consumption and peak demand during the planning period?

We summarize the E3 High Electrification sensitivity in Appendix F4, and provide as Attachment A to that Appendix, E3's detailed discussion of their methodology.

3. Summary

We believe planning for electrification must contemplate a variety of future state scenarios, but also that EVs and electrification broadly are not a primary driver that will influence resource decisions in this Resource Plan. We are continuing to refine our EV forecasting methods as we learn more about the EV industry and adoption trends nationally. We expect to provide updated EV-specific forecast scenarios in our November 2019 IDP.

APPENDIX F2 – STRATEGIST MODELING ASSUMPTIONS & INPUTS

A. Discount Rate and Capital Structure

The discount rate used for levelized cost calculations and the present value of modeled costs is 6.53 percent. The rates shown below were calculated by taking a weighted average of each NSP jurisdiction's last allowed/settled electric retail rate case.

Table 1: Discount Rate and Capital Structure

Discount Rate and Capital Structure				
	Capital Structure	Allowed Return	Before Tax Electric WACC	After Tax Electric WACC
Long-Term Debt	46.16%	4.80%	2.22%	1.60%
Common Equity	52.35%	9.35%	4.90%	4.90%
Short-Term Debt	1.49%	3.65%	0.05%	0.04%
Total			**7.17%**	**6.53%**

B. Inflation Rates

The inflation rates are used for existing resources, generic resources, and other costs related to general inflationary trends in the modeling and are developed using long-term forecasts from Global Insight. The general inflation rate of 2% is from their long-term forecast for "Chained Price Index for Total Personal Consumption Expenditures" published in the second quarter of 2018.

C. Reserve Margin

The reserve margin at the time of MISO's peak is 8.4 percent from the 2018-2019 LOLE Study Report published November 2017. The coincidence factor between the NSP System and MISO system peak is 5 percent. Therefore, the effective reserve margin is:

$$(1 - 5\%) * (1 + 8.4\%) - 1 = 2.98\%.$$

D. CO_2 Costs

The PVSC Base Case CO2 values are based on the high environmental cost values for CO2 through 2024 (page 31 of the Minnesota Public Utilities Commission's Order Updating Environmental Cost Values in Docket No. E999/CI-14-643 issued January 3, 2018.). All prices are converted to 2018 real dollars using the 2017 GPDIPD of

113.416 and then escalate at general inflation thereafter.

The PVSC Base Case values starting in 2025 are based on the "high" end of the range of regulated costs (see page 12 of MPUC Order Establishing 2018 and 2019 Estimate of Future Carbon Dioxide Regulation Costs in Dockets No.E999/CI-07-1199 and E-999/DI-17-53 issued June 11, 2018). All prices escalate at general inflation.
The Order Establishing 2018 and 2019 Estimate of Future Carbon Dioxide Regulation Costs requires four alternative scenarios to be run in addition to the PVSC Base Case. The Order Extending Deadline for Filing Next Resource Plan issued January 30, 2019 also requires a scenario using the midpoint of the Commission's most recently approved externalities and regulatory costs of carbon. The values in the PVSC Base Case and alternative scenarios are set out below.

Table 2: CO2 Costs

CO2 Costs ($ per short ton)						
Year	Low Environmental Cost	High Environmental Cost	Low Environmental/ Regulatory Costs	Mid Environmental/ Regulatory Costs	PVSC - High Environmental/ Regulatory Costs	PVRR - Omitting CO2 Cost Considerations
2018	$9.09	$42.76	$9.09	$25.92	$42.76	$0.00
2019	$9.49	$44.58	$9.49	$27.04	$44.58	$0.00
2020	$9.90	$46.45	$9.90	$28.18	$46.45	$0.00
2021	$10.32	$48.39	$10.32	$29.35	$48.39	$0.00
2022	$10.77	$50.38	$10.77	$30.57	$50.38	$0.00
2023	$11.22	$52.43	$11.22	$31.82	$52.43	$0.00
2024	$11.69	$54.55	$11.69	$33.12	$54.55	$0.00
2025	$12.16	$56.72	$5.00	$15.00	$25.00	$0.00
2026	$12.67	$58.97	$5.10	$15.30	$25.50	$0.00
2027	$13.17	$61.29	$5.20	$15.61	$26.01	$0.00
2028	$13.70	$63.67	$5.31	$15.92	$26.53	$0.00
2029	$14.24	$66.12	$5.41	$16.24	$27.06	$0.00
2030	$14.80	$68.64	$5.52	$16.56	$27.60	$0.00
2031	$15.37	$71.24	$5.63	$16.89	$28.15	$0.00
2032	$15.97	$73.91	$5.74	$17.23	$28.72	$0.00
2033	$16.57	$76.67	$5.86	$17.57	$29.29	$0.00
2034	$17.21	$79.50	$5.98	$17.93	$29.88	$0.00
2035	$17.85	$82.41	$6.09	$18.28	$30.47	$0.00
2036	$18.52	$85.41	$6.22	$18.65	$31.08	$0.00
2037	$19.20	$88.50	$6.34	$19.02	$31.71	$0.00
2038	$19.91	$91.68	$6.47	$19.40	$32.34	$0.00
2039	$20.62	$94.96	$6.60	$19.79	$32.99	$0.00
2040	$21.38	$98.32	$6.73	$20.19	$33.65	$0.00
2041	$22.14	$101.78	$6.86	$20.59	$34.32	$0.00
2042	$22.94	$105.34	$7.00	$21.00	$35.01	$0.00
2043	$23.74	$109.00	$7.14	$21.42	$35.71	$0.00
2044	$24.58	$112.76	$7.28	$21.85	$36.42	$0.00
2045	$25.43	$116.63	$7.43	$22.29	$37.15	$0.00
2046	$26.33	$120.61	$7.58	$22.73	$37.89	$0.00
2047	$27.23	$124.71	$7.73	$23.19	$38.65	$0.00
2048	$28.17	$128.92	$7.88	$23.65	$39.42	$0.00
2049	$29.12	$133.24	$8.04	$24.13	$40.21	$0.00
2050	$30.12	$137.69	$8.20	$24.61	$41.02	$0.00
2051	$31.14	$142.26	$8.37	$25.10	$41.84	$0.00
2052	$32.18	$146.97	$8.53	$25.60	$42.67	$0.00
2053	$33.26	$151.80	$8.71	$26.12	$43.53	$0.00
2054	$34.36	$156.76	$8.88	$26.64	$44.40	$0.00
2055	$35.50	$161.87	$9.06	$27.17	$45.28	$0.00
2056	$36.66	$167.11	$9.24	$27.71	$46.19	$0.00
2057	$37.86	$172.51	$9.42	$28.27	$47.11	$0.00

E. All Other Externality Costs

The values of the criteria pollutants are derived from the high and low values for each of the 3 locations, as determined in the Minnesota Commission Order Updating Environmental Cost Values in Docket No. E999/CI-14-643 issued January 3, 2018.

The midpoint externality costs are the average of the low and high values. All prices are escalated to 2018 real dollars using the 2017 GPDIPD of 113.416. The high, low and midpoint externality costs will be used in the CO2 sensitivities as described above.

Table 3: Externality Costs

MPUC Low Externality Costs 2018 $ per short ton				
	Urban	Metro Fringe	Rural	<200mi
SO2	$6,116	$4,829	$3,643	$0
NOx	$2,934	$2,622	$2,110	$28
PM2.5	$10,697	$6,856	$3,654	$872
CO	$1.65	$1.17	$0.31	$0.31
Pb	$4,857	$2,562	$624	$624

MPUC High Externality Costs 2018 $ per short ton				
	Urban	Metro Fringe	Rural	<200mi
SO2	$15,288	$12,030	$8,878	$0
NOx	$8,390	$7,798	$6,771	$158
PM2.5	$26,721	$17,091	$8,973	$1,327
CO	$3.51	$2.08	$0.63	$0.63
Pb	$6,011	$3,094	$695	$695

MPUC Midpoint Externality Costs 2018 $ per short ton				
	Urban	Metro Fringe	Rural	<200mi
SO2	$10,702	$8,430	$6,261	$0
NOx	$5,662	$5,210	$4,441	$93
PM2.5	$18,709	$11,974	$6,313	$1,099
CO	$2.58	$1.63	$0.47	$0.47
Pb	$5,434	$2,828	$659	$659

F. Demand and Energy Forecast

The Company's fall 2018 load forecast is used as the base assumption and assumes that EV impacts grow through 2023 are then held constant for the remaining forecast period. The energy efficiency (EE) forecast included in this forecast assumes impacts at a 75 percent rebate level which equals roughly 1.5 percent of sales through the planning period.

The "Load Forecast with 1.5% EE" shown in Table 4 below is the starting point for the Strategist load inputs. In all modeling scenarios, the "1.5% EE" is removed - the removal of these EE program effects, which have a 14-year life, impacts the load forecast through 2047. In its place, three EE Bundles (discussed below) are included

in Strategist as Proview Alternatives and any number of these bundles (from 0 to all 3) is allowed to be selected as part of the optimization process. The resulting forecast, before the optimized EE bundles are added, is shown below in Table 4 as "Forecast Without 1.5% EE." The forecasts shown do not include the impact of DG solar, as DG solar is modeled as a resource in Strategist, not a load modifier.

Table 4: Strategist Demand and Energy Forecast

Demand and Energy Forecast				
	Demand (MW)		Energy (GWh)	
Year	Forecast with 1.5% EE	Forecast without 1.5% EE	Forecast with 1.5% EE	Forecast without 1.5% EE
2018	9,152	9,152	43,914	43,914
2019	9,136	9,136	43,798	43,798
2020	9,156	9,227	43,865	44,310
2021	9,191	9,333	43,560	44,447
2022	9,251	9,464	43,529	44,860
2023	9,285	9,569	43,394	45,168
2024	9,329	9,684	43,425	45,650
2025	9,354	9,780	43,257	45,919
2026	9,403	9,900	43,281	46,386
2027	9,487	10,055	43,493	47,042
2028	9,593	10,262	44,089	48,093
2029	9,635	10,403	43,972	48,408
2030	9,697	10,567	44,130	49,010
2031	9,740	10,713	44,172	49,496
2032	9,856	10,956	44,661	50,445
2033	10,005	11,211	44,875	51,087
2034	10,137	11,343	45,232	51,443
2035	10,248	11,368	45,534	51,302
2036	10,374	11,408	46,042	51,382
2037	10,482	11,430	46,126	51,006
2038	10,576	11,438	46,287	50,723
2039	10,674	11,449	46,541	50,534
2040	10,777	11,467	46,946	50,505
2041	10,873	11,476	46,975	50,081
2042	10,964	11,481	47,143	49,805

2044	11,169	11,514	47,823	49,603
2045	11,241	11,500	47,879	49,210
2046	11,328	11,500	48,076	48,964
2047	11,424	11,510	48,372	48,816
2048	11,536	11,536	48,977	48,977
2049	11,626	11,626	48,811	48,811
2050	11,715	11,715	49,042	49,042
2051	11,804	11,804	49,274	49,274
2052	11,893	11,901	49,640	49,640
2053	11,982	11,992	49,736	49,736
2054	12,071	12,083	49,968	49,968
2055	12,160	12,174	50,199	50,199
2056	12,249	12,265	50,567	50,567
2057	12,339	12,356	50,662	50,662

The low load sensitivity includes high customer-adoption-based DG/DER growth and higher EE savings, which reduces load. The high load sensitivity includes high electrification load. These assumptions are shown in Table 5 and Table 6, and are incremental/decremental to the forecast shown in Table 4.

G. Energy Efficiency Bundles

The EE "Program" and "Maximum" Bundles are based on the Minnesota Department of Commerce's Minnesota Energy Efficiency Potential Study: 2020-2029 published December 4, 2018. The "Optimal" Bundle was developed by the Company. The bundles are incremental to the "Forecast without 1.5% EE" shown in Table 4. They are also dependent on the Bundle before it being selected (i.e. Bundle 2 cannot be selected if Bundle 1 is not selected). The Bundles are included in Strategist as Proview Alternatives and any number of these Bundles (from 0 to all 3) is allowed to be selected as part of the optimization process.

H. Demand Response Forecast

The base demand response forecast was developed by the Company and is included in all scenarios and sensitivities. The three demand response "Bundles" are from the Brattle Potential Study provided as Appendix G2. The Bundles are incremental to the base demand response forecast and, the same as for EE, are dependent on the Bundle before it being selected (i.e. Bundle 2 cannot be selected if Bundle 1 is not selected). These Bundles are included in Strategist as Proview Alternatives and any number of

the Bundles (from 0 to all 3) is allowed to be selected as part of the optimization process.

Table 8: Demand Response Forecast

**Demand values are coincident to system peak.*

I. Fuel Price Forecasts

The natural gas prices are developed using a blend of market information (New York Mercantile Exchange futures prices) and long-term fundamentally-based forecasts from Wood Mackenzie, Cambridge Energy Research Associates (CERA) and Petroleum Industry Research Associates (PIRA).

Coal price forecasts are developed using two major inputs: the current contract volumes and prices combined with current estimates of required spot volumes and prices to cover non-contracted coal needs. Typically coal volumes and prices are under contract on a plant by plant basis for a one to five year term with annual spot volumes filling the estimated fuel requirements of the coal plant based on recent unit dispatch. The spot coal price forecasts are developed from price forecasts provided by Wood Mackenzie, JD Energy, and John T Boyd Company, as well as price points from recent Request for Proposal (RFP) responses for coal supply. Added to the spot coal forecast, which is just for the coal commodity, are: transportation charges, SO_2 costs, freeze control and dust suppressant, as required.

In addition to resources that exist within the NSP System, the Company is a participant in the MISO Market. Electric power market prices are developed from fundamentally-based forecasts from Wood Mackenzie, CERA and PIRA using a similar methodology as is used for the gas price forecast. Table 9 below shows the market prices under zero CO_2 cost assumptions. The market purchases and sales limit for transaction volume between the Company and MISO is 1,350 MWh/h in 2018, 1,800 MWh/h from 2019-2022, and 2,300 MWh/h for 2023 and beyond.

High and low price sensitivities were performed by adjusting the growth rate up and down by 50 percent from the base forecast starting in year 2022.

**Coal prices are delivered prices, while gas and market prices are hub prices.*

J. Baseload Retirement "Leave Behind" Costs

Based on the MISO Y2 retirement studies performed on existing coal and nuclear resources, the Company developed transmission reinforcement or "leave behind" estimates, which reflect costs required to mitigate localized grid impacts of the retirement of major baseload resources. The reinforcement costs are included as a one-time charge based on the timing of the resource retirement.

Specifically, we have included the following proxy leave behind costs related to our baseload resource retirements as estimated from the MISO studies. We applied these costs in the modeling as soon as the resource is retired, over a three year period, to reflect the estimated local transmission reinforcement costs assumed to be required upon retirement. All numbers below are in real dollar terms ($2020).

- King: $48 million
- Sherco 3: $48 million
- Monticello: $96 million
- Prairie Island 1: $96 million
- Prairie Island 2: $96 million

K. Surplus Capacity Credit

The surplus capacity credit of up to 500 MW is applied for all twelve months of each year and is priced at the avoided capacity cost of a generic brownfield H-Class combustion turbine on an economic carrying charge basis.

Table 10: Surplus Capacity Credit

Surplus Capacity Credit																				
	2018	2019	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037

L. Effective Load Carrying Capability (ELCC) Capacity Credit for Wind, Solar, and Battery Resources

The ELCC for existing wind units is based on current MISO accreditation. The ELCC for generic wind is equal to 15.6% of their nameplate rating per MISO 2017/2018 Wind Capacity Report. The ELCC for generic solar is 50% of the AC nameplate capacity. The ELCC for a generic 4-hour battery is equal to 100% of their AC equivalent capacity.

M. Spinning Reserve Requirement

Spinning reserve is the on-line reserve capacity that is synchronized to the grid to maintain system frequency stability during contingency events and unforeseen load swings. The level of spinning reserve modeled is 137 MW and is based on a 12 month rolling average of spinning reserves carried by the NSP System within MISO.

N. Emergency Energy

Emergency energy is $500/MWh and is used to cover events where there are not enough resources available to meet system energy requirements.

O. Transmission Delivery Costs and Interconnection Costs

Transmission delivery costs for generic resources were developed by the Company. They are based on evaluation of recent and historical MISO studies and queue results. These costs represent "grid upgrades" to ensure deliverability of energy from these facilities to the overall bulk electric system.

We note additionally that interconnection costs for generic resources are included in the capital costs in Table 14 in Part U of this Appendix, and represent "behind the fence" costs associated with substation and representative gen-tie construction.

Table 11: Transmission Delivery Costs

Transmission Delivery Costs				
	CC	CT	Wind	Solar
$/kw	500	200	400	140

P. Integration and Congestion Costs

Integration costs are taken from studies conducted by Enernex and apply to new wind and solar resources only. Congestion costs were developed by the Company using the MISO MTEP 2018 models and looking at the average congestion costs between representative wind bus locations and NSP.NSP. Congestion costs are applied to new wind projects only.

Table 12: Integration and Congestion Costs

Integration and Congestion Costs ($/MWh)

Q. Distributed Generation and Community Solar Gardens

The distributed solar inputs are based on the most recent Company forecasts. Annual additions are modeled assuming a degradation of half a percent annually in generation, and a twenty five year service life. After a "vintage" of additions reach end of life, it is assumed 90% of the capacity is replaced at then-current costs. The Company expects

a transition from Solar*Rewards to non-incentivized DG over time due to the end of statutory provisions.

Table 13: Distributed Solar Forecast

Distributed Solar (Nameplate MW)				
Year	Solar Rewards	Net Metered	Community Gardens	Total
2018	29	18	246	293

R. Owned Unit Modeled Operating Characteristics and Costs

Company owned units are modeled based upon their tested operating characteristics and projected costs. Below is a list of typical operating and cost inputs for each

company owned resource.

a. Retirement Date
b. Maximum Capacity
c. Current Unforced Capacity (UCAP) Ratings
d. Minimum Capacity Rating
e. Seasonal Deration
f. Heat Rate Profiles
g. Variable O&M
h. Fixed O&M
i. Maintenance Schedule
j. Forced Outage Rate
k. Emission rates for SO_2, NO_x, CO_2, Mercury and particulate matter (PM)
l. Contribution to spinning reserve
m. Fuel prices
n. Fuel delivery charges

S. Thermal Power Purchase Agreement (PPA) Operating Characteristics and Costs

PPAs are modeled based upon their tested operating characteristics and contracted costs. Below is a list of typical operating and cost inputs for each thermal PPA.

a. Contract term
b. Maximum Capacity
c. Minimum Capacity Rating
d. Seasonal Deration
e. Heat Rate Profiles
f. Energy Schedule
g. Capacity Payments
h. Energy Payments
i. Maintenance Schedule
j. Forced Outage Rate
k. Emission rates for SO_2, NO_x, CO_2, Mercury and PM
l. Contribution to spinning reserve
m. Fuel prices
n. Fuel delivery charges

T. Renewable Energy (PPAs and Owned) Operating Characteristics and Costs

PPAs are modeled based upon their tested operating characteristics and contracted costs. Company owned units are modeled based upon their tested operating characteristics and projected costs. Below is a list of typical operating and cost inputs for each renewable energy unit.

a. Contract term
b. Name Plate Capacity
c. Accredited Capacity
d. Annual Energy
e. Hourly Patterns
f. Capacity and Energy Payments
g. Integration Costs

Wind hourly patterns are developed through a "Typical Wind Year" process where individual months are selected from the years 2014-2017 to develop a representative typical year. Actual generation data from the selected months is used to develop the profile for each wind farm. For farms where generation data is not complete or not available, data from nearby similar farms is used.

Solar hourly patterns are taken from the ELCC Study from Fall 2013 and updated to reflect the ELCC as stated above.

U. Generic Assumptions

Generic resources are modeled based upon their expected operating characteristics and projected costs. Generic thermal costs are developed by the Company. Generic battery costs are based on Public Service of Colorado All-Source Solicitation bids (Nov 28, 2017) with a 10% annual price improvement rate. Generic renewable costs and capacity factors are from National Renewable Energy Laboratory's 2018 Annual Technology Baseline data. Utility-scale wind and solar costs shown in Tables 16-18 include transmission costs from Table 10, while DG/distributed solar does not.

The Reference Case assumes "no going back" on renewables, meaning that we are committed to pursuing repowering and/or contract extension opportunities for renewable resources that will expire , and renewable resources are replaced "in-kind" when they reach end of life. Starting in 2023, generic solar is added to maintain at a minimum the 2015 IRP Preferred Plan solar levels. In 2023, there is approximately 1,800 GWhs of solar (both utility scale and DG solar) on the system which will grow to approximately 4,500 GWhs by 2028. The Company has already procured the levels

of wind contemplated in the previous Resource Plan, so no minimum level of generic wind additions are needed. Additional renewables are included as Proview Alternatives.

In addition to base cost data for renewables, low and high costs are used for various sensitivities. Low and high wind and solar costs are based on the National Renewable Energy Laboratory's 2018 Annual Technology Baseline data. Low and high battery costs are based the percent difference in the NREL ATB low / high battery costs compared to the NREL ATB base costs, with this percent difference applied to the Company's base battery cost forecast. Below is a list of typical operating and cost inputs for each generic resource.

ATTACHMENT A: HEAT RATE UPDATED

In Docket No. E999/CI-06-159 (In the Matter of Commission Investigation and Determination under the Electricity Title, Section XII, of the Federal Energy Policy Act of 2005), the Minnesota Commission required the Company to file information on the fossil fuel efficiency (heat rate) of our generation units, and actions we are taking to increase the fuel efficiency of those units.

Heat rate data for the Company's owned generating units is provided publicly in our annual Federal Energy Regulatory Commission (FERC) Financial Report, FERC Form No. 1. We include a copy of the pertinent unit heat rate data from FERC Form No. 1 for 2018 in Table 21 below.

Table 21: 2018 FERC Heat Rates

Unit	Heat Rate
AS King	10,013
Sherco	10,546
Monticello	10,505
Prairie Island	10,487
Black Dog (NG)	7,870
High Bridge	6,863
Riverside	7,172
French Island	23,570
Wilmarth	10,637

The Company's Performance Monitoring department performs routine heat rate testing and conducts heat balances of its generating units. In addition, testing, assessments, and reporting on boilers, air heaters, cooling towers, and enthalpy drop tests on steam turbines are also conducted. These tools factor into our assessment of the condition of these individual components, as well as how their respective performance levels will impact the overall efficiency of a given generating unit. Table 22 below shows a summary of NSP System heat rate testing from 2015-2018.

Table 22: Heat Rate Tests – 2015-2018

Plant/Unit	Type of Unit Test	Type of Test	Year Tested
Sherco U1	Coal Boiler	Heat Rate	2015
Bayfront U4	Combustion Turbine	Calculated Adjustment for Fuel Change	2016
King U1	Coal Boiler	Heat Rate	2016
Sherco U2	Coal Boiler	Heat Rate	2015, 2016
Black Dog U5/U2	Combined Cycle	Heat Rate	2015, 2017
High Bridge CC	Combined Cycle	Heat Rate	2017, 2018
Sherco U3	Coal Boiler	Heat Rate	2017
Black Dog U6	Combustion Turbine	Heat Rate	2018
Riverside U7,U9,U10	Combined Cycle	Heat Rate	2017,2018

As part of its heat rate testing and reporting protocol, the Performance Monitoring group identifies potential heat rate improvement opportunities and validates actual performance enhancements. The Company does not look at heat rate improvements in isolation when considering plant improvement projects; rather, we perform a collective assessment of potential safety, efficiency, and environmental performance improvements as well as overall economics in developing our generation asset management objectives. Looking forward, the Company plans to continue our proactive cycle of heat rate testing and overall unit assessments at our generation units and implement improvements as opportunities arise.

ATTACHMENT B: WATER AND PLANT OPERATIONS

The Minnesota Commission's August 5, 2013 Notice of Information in Future Resource Plan Filings in Docket No. E002/RP-10-825 suggested utilities should consider adding to their initial resource plan filings the supplemental information listed at page 4 of the Commission's May 10, 2013 Order in Minnesota Power Docket No. E015/RP-13-53 (Order Point No. 4).

The Company's generating units are geographically positioned along major Minnesota waterways. The access to water accommodates the thermal needs of these generating units. As such, the Company's plant operations are governed by and comply with all applicable cooling water intake and discharge rules and regulations, which may indirectly affect Strategist modeling as discussed below.

The Clean Water Act Section 316(a) sets thermal limitations for discharges and the criteria and processes for allowing thermal variances. The Company's power plant discharge temperature limits and allowances for thermal emergency provisions are

outlined in the plants' National Pollutant Discharge Elimination System (NPDES) permits. Additionally, Xcel Energy has policies which outline the conditions and procedures to implement during periods of energy emergencies that allow for limited thermal variances.

Section 316(b) of the Clean Water Act governs the design and operation of intake structures in order to minimize adverse environmental impacts to aquatic life. EPA issued new rules in August 2014 that will impact all plants that withdraw water for cooling purposes. The new rules require improvements to intake screening technology to minimize the number of aquatic organisms that are killed due to being stuck to the screens (referred to as "impingement). The rules also created a process for the state permitting agency to evaluate and determine if additional improvements are required to minimize the number of smaller organisms that pass through the intake screens and enter the plant cooling water system (referred to as "entrainment"). While the costs associated with the impingement compliance requirements are definable, the costs associated with the entrainment compliance requirements are uncertain.

Timing of the compliance requirements is site-specific and is determined by each site's NPDES permit renewal timeline.

While specific conditions, such as high water discharge temperatures, are not directly modeled in Strategist, the model reflects the impact of reducing plant output due to high water temperatures. Modeling in Strategist includes two methods to account for impacts due to changes in plant operations: each resource is modeled using a unit specific median unforced capacity rating, and the system needs are modeled with a planning reserve margin. By modeling the system needs with a planning reserve margin, the base level of required resources is assumed to be higher than those needed to meet the forecasted peak system demand. By modeling all units with an assumed level of forced outage, the base level of all available resources, modeled in aggregate, is assumed to be sufficient to represent resource availability due to emergency changes in plant operations. Thus the impact of reducing plant output due to high water temperatures is reflected through corrections to both obligation and resource adjustments.

ATTACHMENT C: ICAP LOAD AND RESOURCES TABLE

The following table shows load and resources using Installed Capacity Rating (ICAP) for the planning period, in compliance with the Minnesota Commission's August 5, 2013 Notice of Information in Future Resource Plan Filings.[1]

APPENDIX F4 – HIGH ELECTRIFICATION SCENARIO DESCRIPTION

We worked with Energy and Environmental Economics (E3) to develop a High Electrification load forecast sensitivity, derived from the E3 statewide decarbonization analysis using PATHWAYS.[1] The objective of this sensitivity was to create a "bookend," examining the possible impacts on load growth and peak demand growth on our Upper Midwest NSP System service area, under a scenario with electrification sufficiently aggressive to achieve Minnesota's economy-wide goal of an 80 percent reduction in greenhouse gas (GHG) emissions below 2005 levels by 2050.[2] The Company does not suggest this amount of electrification is likely to occur, absent additional policy measures. We note that an 80 percent economy-wide reduction could theoretically be achieved with less electrification and more of other measures.

Without suggesting this much electrification will or should occur, the sensitivity asks: if there were very aggressive electrification of transportation, buildings, and other end uses, what are the potential impacts on energy consumption and peak demand during the planning period?

I. METHODS

E3 details its methodology in Attachment A to this Appendix. In summary, E3 began with the High Electrification scenario developed in its Minnesota PATHWAYS analysis.[3] In that analysis, E3 created two scenarios, High Electrification and High Biofuels, both targeting the 80 percent by 2050 economy-wide goal. The High Electrification scenario assumes low-carbon electricity (48 percent zero-carbon generation by 2025, 90 percent by 2050) and a high amount of energy efficiency – including high-efficiency appliances and building shell weatherization. All light, medium, and heavy-duty vehicle sales are electric by 2050; sales of electric heat pump equipment reach 95 percent by 2050, replacing electric, natural gas and LPG alternatives; and 50 percent of liquid fuels used in agriculture are electrified by 2050. As a result, statewide total electricity demand grows 60 percent by 2050, relative to 2015. Load growth is especially pronounced in the latter years (2035-2050).

E3 then developed hourly load shapes for each electrified end use, using simulated

[1] In summary, for the PATHWAYS study, E3 developed a set of long-term economy-wide, deep decarbonization scenarios for the state of Minnesota. These scenarios provide an exploration of the cross-sectoral implications of meeting economy-wide carbon reduction goals, and highlight the role of Xcel Energy, and the electric sector as a whole, in meeting the state's economy-wide carbon goal. For details, see the E3 Minnesota PATHWAYS Report as Appendix P3.

[2] Minn. Stat. 216H.02, Subd. 1. *See* https://www.pca.state.mn.us/air/state-and-regional-initiatives.

[3] This analysis is summarized in E3 presentations from September 24 and October 23, 2018. *See* https://www.xcelenergy.com/company/rates_and_regulations/resource_plan_overview/midwest_energy_plan and, under Current Status, the 9/24/18 and 10/23/18 Workshop Materials.

demand by year based on a 2009 weather year. Water heating, which becomes dominated by heat pump water heaters, is assumed to be a "managed" load capable of being limited largely to off-peak hours. Passenger EVs are assumed to be mostly (90 percent) managed to avoid peak demand impacts. This is based on the experience of Xcel Energy and other utilities, that most charging happens at home and that it will likely be feasible, with a combination of technological controls and time-sensitive rates, to incentivize EV owners to mostly avoid on-peak charging. Heavier EVs and agricultural electrification are conservatively assumed to be flat across hours, i.e. an unmanaged load.

Electrified space heating, however, has a significant potential impact on total energy and peak demand, and is less amenable to being managed to off-peak hours. E3 assumed an increasing share of space heating is served by electric air-source heat pumps (ASHPs), which face special challenges in cold climates. Because efficiency of ASHPs decreases as outdoor air temperature drops, ASHPs are paired with backup electric resistance and thermal heating in this scenario. Below 0° Fahrenheit, there is a non-linear increase in input energy needs as an increasing share of heat is provided by electric resistance backup. See Attachment A to this Appendix for greater detail.

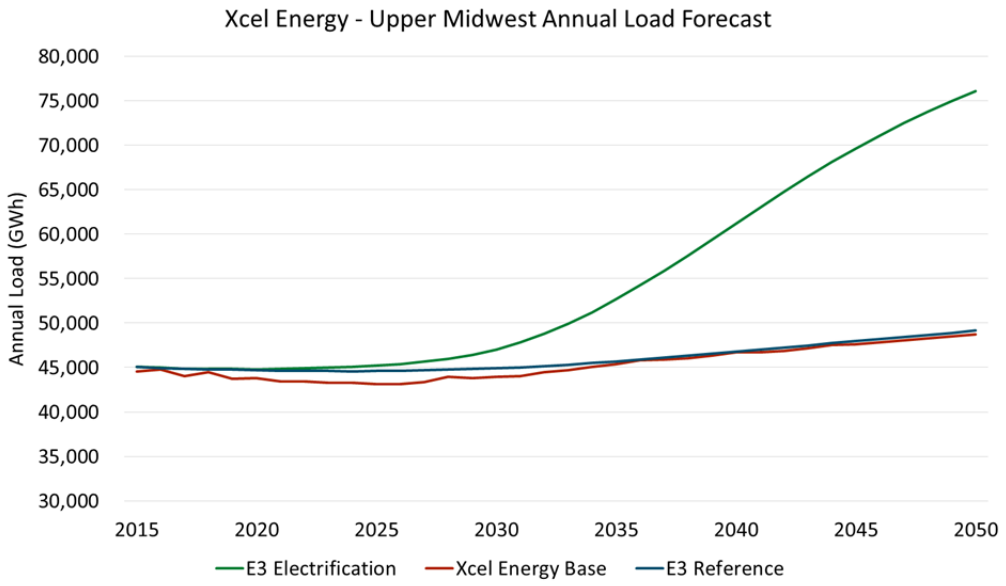
Finally, E3 scaled the Minnesota-wide results to the NSP System, i.e. Xcel Energy's service territory across five Upper Midwest states. Based on historical energy data, in recent years Xcel Energy's retail sales in those five states have been on average 67 percent of total retail sales in Minnesota, so E3's forecast of load and peak demand Minnesota-wide is multiplied by 67 percent to derive load and peak demand for the NSP System under this High Electrification sensitivity. This approach assumes that the scaling of Minnesota loads to the NSP System stays constant over the forecast period. If electrification of transportation, water, and space heating has a different growth rate in our Upper Midwest service territories than in Minnesota as a whole, then both energy and demand impacts could be significantly different for Xcel Energy.

II. RESULTS

Even with aggressive electrification of transportation, water heating and space heating, impacts on incremental energy and peak demand needs are relatively slight during the 2020-2034 Resource Plan planning period – but much more significant by 2050. This is primarily because adoption of EVs and electrified appliances reaches its "hockey stick" phase only near the end of the planning period. Further, even once electric alternatives dominate new sales, the stock of vehicles and appliances takes time to turn over.

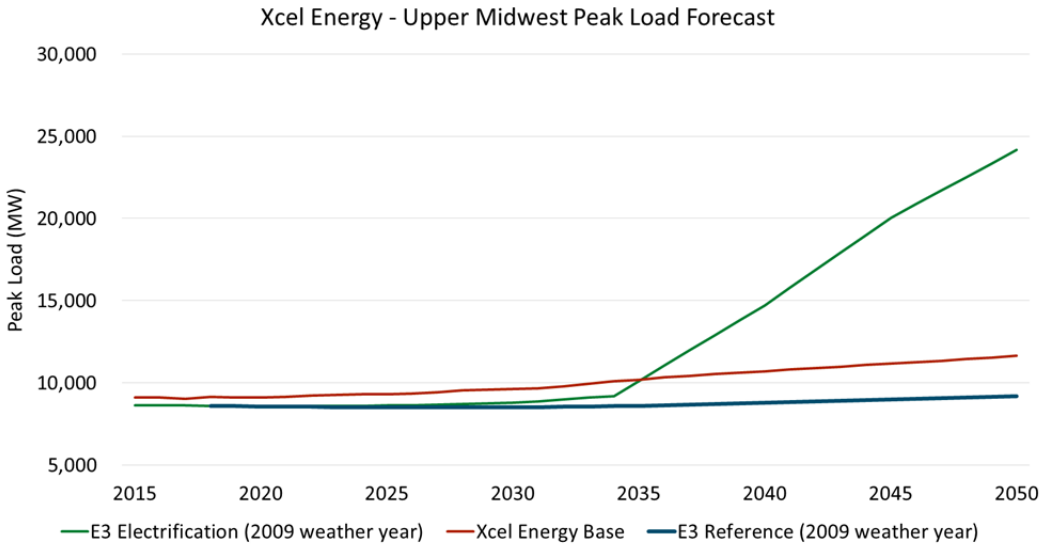
Load Impacts. When compared to E3's reference scenario, the high electrification scenario requires incremental energy on our Upper Midwest system of about 2,000 GWh in 2030 and 5,700 GWh by 2034. Incremental energy requirements increase dramatically thereafter, reaching 14,000 GWh in 2040 and almost 27,000 GWh by 2050. See Figure 1 below.

Figure 1: Incremental Annual Load under a High Electrification Scenario



Peak Demand Impacts. Impacts on peak demand under a high electrification scenario likewise come primarily after the planning period. For example, incremental peak demand requirements due to electrified loads are only 430 MW by 2034, but escalate dramatically thereafter, reaching over 5 GW of incremental peak demand by 2040 and almost 15 GW by 2050. See Figure 2 below.

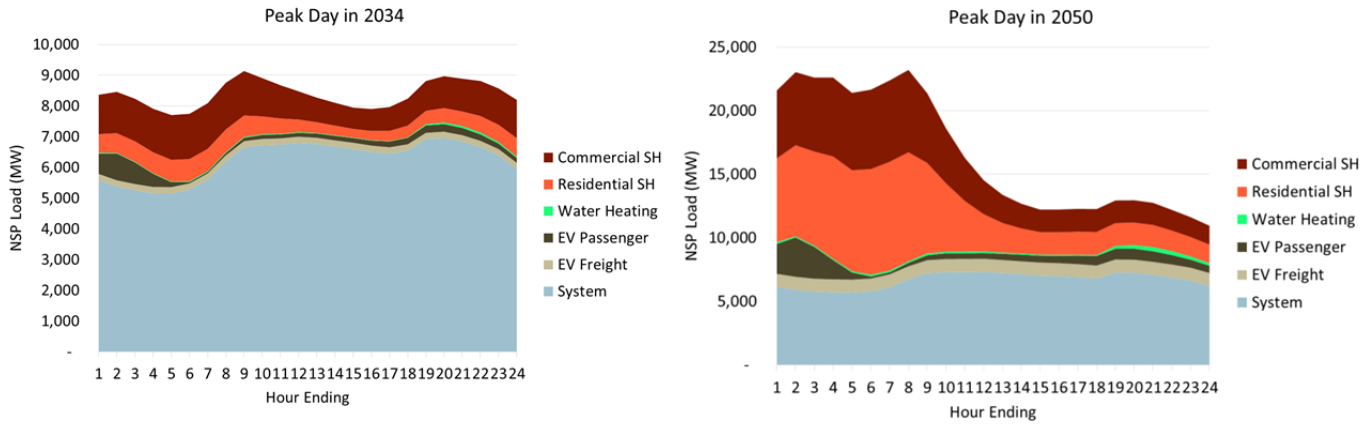
Figure 2: Incremental Peak Demand under a High Electrification Scenario



While some electrified loads, such as passenger EVs and water heating, are able to be managed mostly to off-peak hours, space heating has a significant peak demand impact since heating is needed round-the-clock. Figure 3 below shows peak demand in 2034 and 2050, illustrating both that the bulk of peak demand needs are from residential and commercial space heating – and, that space heating imposes incremental peak demand needs in all hours. After about 2034, our Upper Midwest NSP System becomes a winter peaking utility in this scenario.

Figure 3: Electricity Demand on a Peak Day in 2034 (Left) and 2050 (Right) under a High Electrification Sensitivity

Note difference in y-axis scale



III. IMPLICATIONS

Achieving Minnesota's goal of an 80 percent economy-wide GHG reduction will be challenging. Because of the progress the electricity sector has made to-date in reducing emissions, and its expected continued progress by 2050, there is significant potential to reduce emissions from other economic sectors using low-carbon electricity, which could help Minnesota achieve its statutory GHG goals. However, if electricity use by other sectors is to grow significantly, it is all the more important to maintain affordable and reliable electricity – highlighting the need to take advantage of economies of scale in pursuing low- and zero-carbon electricity options.

While most of the High Electrification sensitivity's impacts on load and peak demand come beyond the planning period, it is important to avoid a myopic view in planning the energy system to serve this potential demand beyond 2034. Firm capacity needs would increase dramatically just beyond the end of the planning period in this sensitivity. This strengthens the rationale for the Reliability Requirement – a minimum amount of firm, dispatchable resources to meet customers' energy needs whenever they peak, as discussed in Appendix J2: Reliability Requirement. Incremental peak capacity needs can be mitigated to some degree by putting in place time-sensitive rates and technological controls needed to manage electrified loads (EVs, water heating) to off-peak hours and match these flexible loads to hours of high renewable generation. However, as discussed in conjunction with the Reliability Requirement, renewable generation is not always available. Additionally, not all electrified loads are amenable to shifting off-peak, so it will be important to plan the system with a view beyond 2034.

Finally, a strategic electrification (or "beneficial electrification") approach may be preferable to an "electrify everything" approach. Considering cold climate challenges of some types of electrification, the difficulty of managing some electrified loads to off-peak hours, and the relative efficiency of the natural gas local distribution system in providing heat, it makes sense to focus electrification efforts on those end uses where electrification meets criteria such as:

- Reducing system costs for all utility customers;
- Reducing net CO_2 emissions; and
- Providing for a more efficient utilization of grid resources.[4]

[4] As adopted in Colorado Senate Bill 19-236, and similar to the definition of beneficial electrification proposed by the Regulatory Assistance Project in https://www.raponline.org/knowledge-center/beneficial-electrification-ensuring-electrification-public-interest/.

Xcel NSP High Electrification Scenario

Tory Clark

1 Background

This study investigates the potential future of Minnesota's energy economy. We model Minnesota's energy economy on an annual time scale, with key outputs including annual emissions, electric loads, and electric supply changes.

We model two evolutions: the evolution of energy demands and energy supply. To model energy demands we use LEAP, the Long-range Energy Alternatives Planning system. LEAP is an energy accounting framework that provides annual economy-wide energy and emissions results, including a stock roll-over component for major equipment categories (energy uses in buildings and transportation fleet). E3, in partnership with Xcel Energy - Upper Midwest, developed a LEAP model to represent the energy economy of Minnesota (Minnesota PATHWAYS). This model includes developing representation of the Minnesota economy as it exists today, and a series of transformations that reduce economy-wide emissions consistent with achieving the Next Generation Energy Act goal of 80% below 2005 emissions levels by 2050.

We take annual electricity loads from Minnesota PATHWAYS, downscale them to the Xcel Energy - Upper Midwest service territory, and pass them to RESOLVE, E3's electricity capacity expansion and operations model. We use RESOLVE to develop least-cost optimal expansion plans of the electricity grid. Together, the models allow us to track the change in composition of the Minnesota energy economy annually, as well as evaluate how the Xcel Energy - Upper Midwest electric supply could change in a decarbonized future. This document highlights the methods and data surrounding this modeling effort, with a focus on the High Electrification scenario.

The scope of our analysis does not focus on the full scope of greenhouse gas (GHG) emissions, which include agricultural and waste water emissions; we focus on direct energy consumption and energy supply.

Energy forecasting methodology

We begin by tracking the high level economic drivers: population, housing units, square footage, and total vehicle miles traveled (VMT). These data are sourced primarily from various federal and state data sources, including the Census and 2018 AEO. From these economic drivers, we forecast energy demands by using either a stock rollover approach, or a total energy approach.

When infrastructure data is available (such as the number of vehicles) we use a stock rollover approach to model the number of devices and track the improvements in efficiency or change in energy usage as newer, more efficient devices replace retiring devices.

A stock rollover approach allows us to track sales and retirements of devices by technology, track efficiency improvements explicitly, and see the physical lag in the energy system as devices are bought and consumed throughout their lifetimes before being replaced. Note shorter lived technologies, such as lighting and hot water heaters, might roll over multiple times during the study period whereas longer lived technologies, such as power plants and building shells, might roll over only once.

Using a stock rollover approach, the Minnesota PATHWAYS model tracks energy demand associated with existing devices from prior years that have not reached the end of their life. We establish the on-site energy demand associated with these devices by multiplying the number of devices from each vintage with the per-unit energy demand applicable to each vintage.

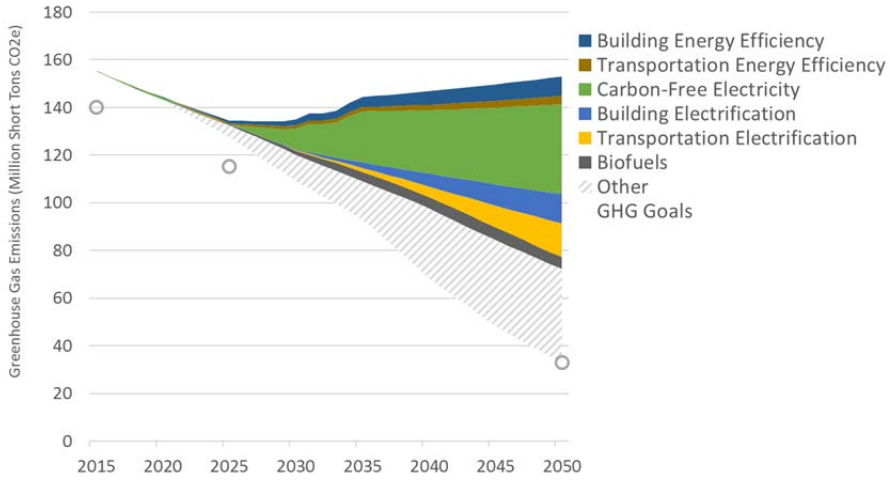
Secondly, we model the number of new devices that are added to each subsector every year. Every year sales of new devices are set to a quantity sufficient to replace retiring devices and meet the demand for new growth (new growth tracks the economic drivers such as housing units or population). Similar to the existing devices, we establish the on-site energy demand associated with new devices by multiplying the number of devices with the appropriate energy usage per device applicable to the new devices' vintage.

When data are limited or of poor quality (such as the industrial sector), we use a total energy approach in which we directly specify the energy demand by fuel, and forecast future energy demands benchmarking to fundamental economic drivers, such as population or AEO energy demand forecasts.

2 Summary of the "High Electrification" scenario:

The High Electrification scenario forecasts a pathway for Minnesota to achieve 80% decarbonization of the energy economy relative to a 2005 base year by 2050. This scenario leans heavily on electrification of end uses wherever practical. An electrification heavy pathway is dependent on carbon-free electricity that is used to displace fossil fuels in buildings and vehicles (Figure 1).

Figure 1. GHG Reductions by Measure: High Electrification Scenario



The high electrification scenario increases load by **60%** in 2050, relative to 2015. Load growth is especially pronounced in the latter years (2035-2050) as load growth from vehicle and space heating electrification exceed energy efficiency gains (Figure 2). For more details on key assumptions see Table 1, below.

Figure 2. Minnesota Load in the High Electrification Scenario

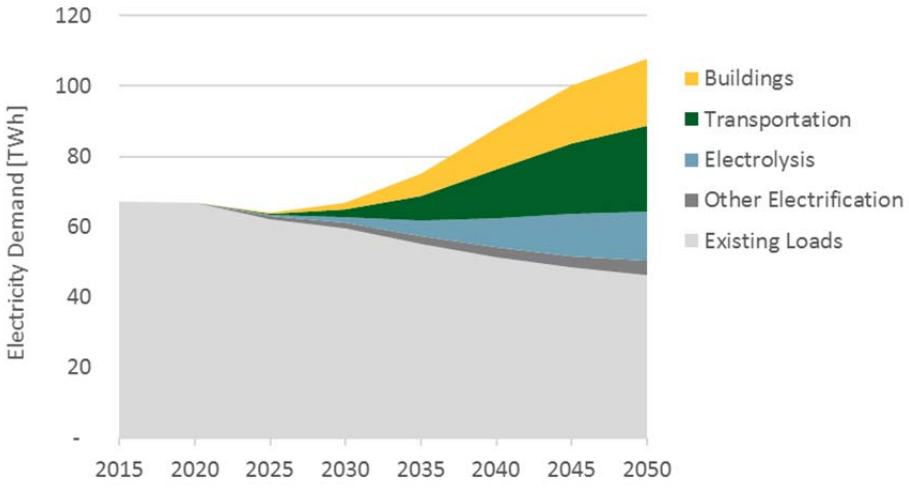


Table 1. Key scenario assumptions

	High Electrification (and low EE)
Electricity generation	
Zero-carbon generation	48% by 2025, 90% by 2050
Nuclear power	Assume nuclear is relicensed or replaced with other carbon-free generation
Buildings	
Energy Efficiency	50% of appliance sales are high-efficiency by 2030 No smart appliances and conservation by 2050 No reduction in demand in nonstock (Residential Other and Commercial Other) demand by 2030, and 30% reduction by 2050
Building Shell and Weatherization	100% adoption of efficient building shell/weatherization measures by 2030
Sales of Electric Heat Pump Equipment	50% by 2030, 95% by 2050, replacing electric, natural gas and LPG
Transportation	
Sales of Zero-Emission Vehicles	LDVs: 50% by 2030, 100% by 2050 MDVs: 50% by 2030, 100% by 2050 HDVs: 40% by 2030, 100% by 2050
Efficiency	Federal CAFÉ standards for LDVs through 2026
Other	50% of Residual Fuel Oil is electrified by 2050
Industry and Other	
Energy Efficiency	No efficiency improvements below baseline
Agriculture Electrification	50% of liquid fuels (Diesel, Gasoline, LPG) are electrified in Agriculture by 2050, at a 50% efficiency improvement due to electrification

3 Electrification load shapes

3.1 Load shapes for water heating and electric vehicles

In developing hourly electric load shapes, this study investigates the electric power system impacts of electrifying a variety of end uses including space heating, water heating, transportation electrification, and others. The next section discusses our space heating load shaping methodology in greater detail. Here we briefly cover the methodology used to create shapes for water heating, transportation electrification, and other electrification.

Water heating: In the High Electrification scenario there is a move towards increased heat pump water heater penetration. E3 used a set of managed heat pump and electric resistance water heating shapes from the Xcel Energy team. The managed resistance water heater shapes are controlled to have no demand from 7am through 6PM. Heat pump water heater shapes are sourced from a broader electricity and decarbonization study commissioned in part by Great River Energy and performed by Brattle in 2016[1]. To capture a representative split of years we use an 80%/20% split of heat pump water heaters / electric resistance water heaters and calculate a blended managed water heating profile. We calculate this profile for a single day that is applied to all the days in a year.

Passenger EV: In the High Electrification scenario there is a move towards increased vehicle electrification, of both passenger and freight. To calculate the load impact of electric passenger EV, E3 used a set of EV load profiles provided by Xcel Energy. These load profiles are sourced from the EV Project, and include both managed and unmanaged charging shapes[2]. For this analysis, we use a blended profile of 90% managed and 10% unmanaged charging. We again calculate this profile for a single day that is applied to all the days in a year.

Freight EV and Agriculture: The final major sources of incremental electrification in the High Electrification scenario are freight vehicles and agriculture. Public data on freight vehicle electric load shapes are sparse. Without accurate, publicly available charging data it is difficult to calculate a representative charging profile for these end uses, so E3 used a flat block across all hours – this indicates that charging demand is consistent across all hours. This is likely not to be accurate, especially if real-time electricity prices fluctuate strongly in future years as these vehicles might exhibit more sophisticated and price responsive charging behavior than the average residential passenger vehicle. Nevertheless, without more data we use a flat charging profile for this study.

In addition to the three categories mentioned above, space heating is the last significant source of electric load growth in the High Electrification scenario. Since space heating has the potential to create operational challenges due to its peaky nature in cold weather, we discuss space heating load shaping in more detail below.

[1] https://greatriverenergy.com/wp-content/uploads/2015/10/Appendices-H-L.pdf
[2] https://www.energy.gov/sites/prod/files/2014/02/f8/nissan_leaf_driving_charging_2011.pdf

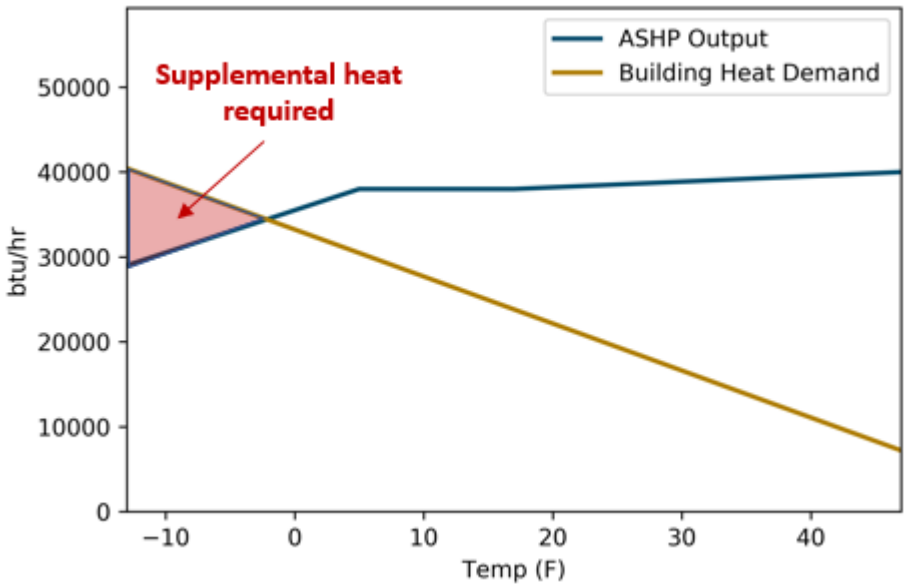
3.2 E3 space heating load shaping methodology

The E3 High Electrification scenario assumes that an increasing share of space-heating loads in Minnesota are served by electric air-source heat pumps (ASHP). ASHPs are relatively rare in Minnesota today, but in the High Electrification scenario adoption of ASHP technologies approaches 90% of state-wide floorspace by 2050. Such a large-scale adoption of ASHPs would add large new, and weather dependent, loads to the state's electricity system.

ASHPs and weather

The efficiency and output capacity of an ASHP decrease as outdoor air temperature drops. When an ASHP can no longer provide enough heat to maintain building comfort, supplemental sources of heat are required (Figure 3**Error! Reference source not found.**). There are two sources of supplemental heat typically used in combination with an ASHP: electric resistance and thermal. For the purposes of the High Electrification scenario we assume that all supplemental heat is served by electric resistance. Where a heat pump can have a coefficient of performance of higher than 2 cold temperatures, the COP of electric resistance heat is 1. The combination of decreasing heat pump efficiency and increasing reliance on electric resistance heat means that ASHPs require non-linear amounts of input power to keep buildings warm in cold weather.

Figure 3: Building Loads and Heat Pump Output

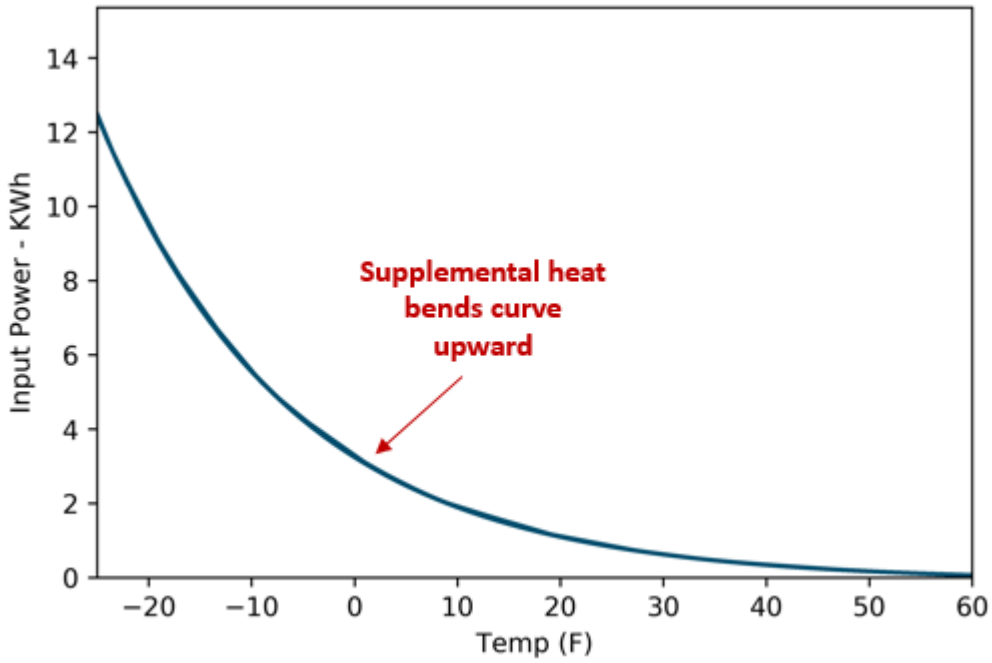


Building simulations and benchmarking

E3 developed relationships between temperature and ASHP loads for both residential and commercial buildings through simulations in the building science software EnergyPlus. E3 used a combination of Federal and local sources (EIA RECS 2015, EIA CBECS 2012, CEE 2018, CEE 2017, Edwards et al 2018) to benchmark the simulations to MN building heat demands.

Figure 4 shows the derived relationship between temperature and a cold climate ASHP load for a typical residential home in Minnesota[3]. The heat pump can cover all of the building's load until 0F, at which point an increasing share of heat is provided by the electric resistance element. By -25F, the ASHP has a COP of 1, the point at which buildings are assumed to be entirely heated by electric resistance.

Figure 4: Residential Heat Pump Load & Temperature



Weather matching

ASHP loads are weather dependent. On a very cold day outdoor air temperatures across Minnesota can vary by a wide margin (Figure 5). For instance, on January 16, 2009 the minimum outdoor air temperature was -5F in Cottonwood County but was -38F during the same hour in Koochinching County. This temperature gradient can lead to very different per-building loads across the state. For instance, a residential building in Cottonwood County with design load of 38 kbtu per hour requires 4 kW of input power to stay warm. That figure for an equivalent building in Koochinching County quadruples to over 16 kW because the heat pump is running entirely in electric resistance back-up mode.

In order to account for the diversity of weather impacts, E3 used a combination of NOAA historical weather data and Census county-level household data. E3 matched NOAA weather stations to their nearest county neighbor in order to develop a geographically explicit per-building load prediction (Figure 5). These shapes were then multiplied by the number of fuel-switching households per county and summed to develop a diversified ASHP shape for Minnesota as a whole. Figure 6 shows the cumulative 2050 loads from ASHP space heaters under a 2009 weather year on both an annual and peak week basis.

[3] The performance of this heat pump is consistent with a top performing 48 kbtu/hr (4-ton) heat pump on the NEEP Cold Climate Heat Pump Product Specification listing.

Figure 5: Minimum Temperatures on January 16, 2009

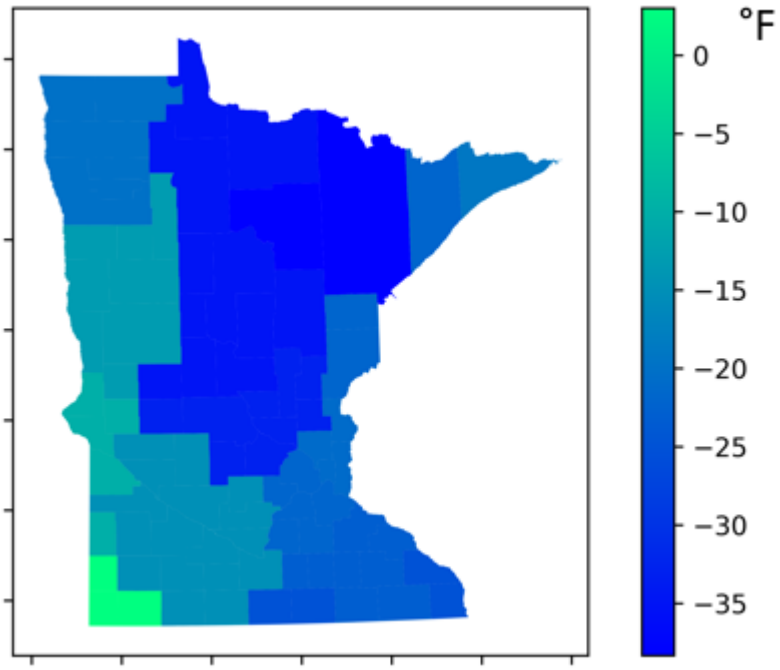


Figure 6: 2050 Residential Space Heat Load

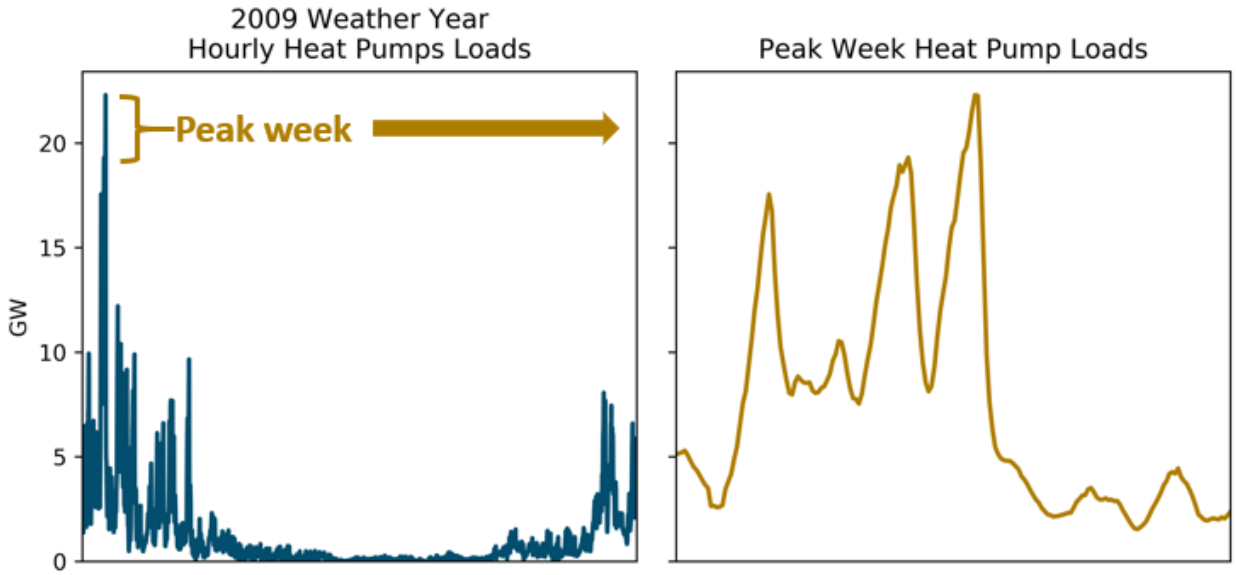

Caveats and limitations

The load shapes developed through the above methodology offer an initial estimation of the scale of loads that follow from a near-complete electrification of space-heating in Minnesota. There are several factors that could make these loads higher or lower. Loads, particularly peak loads, could be higher if homes and businesses do not adopt cold-climate heat pump technologies. Loads could be lower if heat pump technologies continue to improve in cold-climate performance and if buildings heating loads are reduced through weatherization measures. Reduced heating loads decrease the amount of load in peak hours that must be covered by electric resistance back-up heat. Doing so pushes the non-linear portion of the load curve shown on Figure 4 to lower temperatures.

4 Simulating hourly loads

4.1 Forecasting hourly loads

In forecasting the Reference scenario, we project hourly loads by scaling up a historical year of Xcel Energy - Upper Midwest hourly loads according to the total energy in the forecast year. This methodology assumes that the load mix in the Reference scenario changes slowly enough that using a historical load shape will represent the Reference load shapes in the future. Although the Reference scenario has some changes in load across classes, the net load growth is small (0.24%/year) especially in comparison to the High Electrification scenario. Thus, we project hourly loads for the Reference scenario by scaling up each hour according to the total energy in the forecast year. For example, in 2009 the Xcel Energy - Upper Midwest annual load was 44.9 TWh; if the forecast year had an Xcel Energy - Upper Midwest load of 60 TWh we would scale up each hour by 1.33 (60/44.9 = 1.33) to calculate the hourly load for the Reference scenario in the forecasted year.

High electrification load

In calculating the High Electrification scenario load shape, we forecast the annual shape by layering on the incremental amount of electrification we expect in each of the load shaping categories. See Table 2 for the annual incremental electric load in the High Electrification scenario. In earlier years there is some amount of negative load due to efficiency gains[4], but in most categories we see load growth due to electrification.

Table 2. High Electrification scenario incremental annual electric load over Reference scenario (TWh)

	2015	2020	2025	2030	2034	2040	2045	2050
Space Heating	0.0	0.0	0.0	0.2	1.2	3.8	6.1	7.8
Water Heating	0.0	0.0	-0.1	-0.3	-0.2	0.2	0.6	0.8
Passenger EV	0.0	0.0	0.0	0.5	1.6	4.1	5.8	6.5
Other (Freight EV, Agriculture)	0.0	0.1	0.7	1.7	3.1	6.3	9.2	11.8

4.2 Downscaling Minnesota loads for the Xcel Energy - Upper Midwest service territory

[4] This is especially the case for water heaters. Transitioning to heat pump water heaters causes lower load growth than the Reference scenario through 2034

To calculate hourly load shapes for the Xcel Energy - Upper Midwest system, E3 scaled the Minnesota hourly load shapes to Xcel Energy's service territory across five Upper Midwest states. Based on historical energy data, in recent years Xcel Energy's retail sales in those five states have been on average 67% of total retail sales in Minnesota (Table 2). So E3's forecast of load and peak demand Minnesota-wide is multiplied by 67% to derive load and peak demand for the Xcel Energy - Upper Midwest system under this High Electrification sensitivity.

This approach assumes that the scaling of Minnesota loads to the Xcel Energy - Upper Midwest system stays constant over the forecast period. If electrification of transportation, water, and space heating has a different growth rate in our Upper Midwest service territories than in Minnesota as a whole, then both energy and demand impacts could be significantly different for Xcel Energy.

Space heating loads have a significant impact on the estimated peak load, especially in the 2040-2050 timeframe. Using this load shaping methodology for the Xcel Energy – Upper Midwest territory, the incremental peak impact of the High Electrification scenario over the Reference scenario grows from 430 MW in 2034 to over 14 GW in 2050, as the utility shifts from a summer peaking utility to a winter peaking utility due primarily to space heating demands. As noted in the load shaping section above, technology choice matters – foregoing building weatherization and cold climate heat pump technologies could make this peak demand even greater. Other peak mitigation options include non-electric thermal backup sources of heat, or managed load programs (like DR).

Table 2. Minnesota to Xcel Energy - Upper Midwest Scaling Factor[5]

	Xcel Energy - Upper Midwest Annual Load (MWh)	Minnesota Annual Retail Sales (MWh)	Load Share	
2009	44,923,739	64,004,463	70%	
2010	46,188,165	67,799,706	68%	
2011	46,133,452	68,532,708	67%	
2012	45,550,281	67,988,535	67%	
2013	45,177,181	68,644,103	66%	
2014	45,197,106	68,719,367	66%	
2015	44,565,009	66,579,234	67%	
2016	44,670,394	66,546,492	67%	
			67%	**Average**

APPENDIX F5 – GENERATION INTERCONNECTION COSTS METHODOLOGY

Xcel Energy Transmission Planning – White Paper
Generation Interconnection Costs using Random Placement Techniques
June 27, 2018

I. PURPOSE

The purpose of this paper is to articulate Transmission Planning's efforts to create a process to identify interconnection costs associated with renewable generation on the Northern States Power (NSP) System using Monte Carlo simulations.

A. Background

Resource Planning approached Transmission Planning to see if there was a way to identify average transmission upgrade costs associated with solar installations. Running individual cases to create a statistically significant amount of results using the Siemen's PSSE program would be time consuming. Transmission Planning decided to try and develop a Monte Carlo type process to see if we could speed up the process to allow for a large amount of generation placed randomly around the system.

The runtime for each case depend on the amount of contingencies that are chosen to run and the portion of the system you choose to monitor. In addition the case chosen based on its size will greatly affect the runtime (MISO cases vs equivalized MNTACT cases). MNTACT cases used for local NERC reliability have been reduced in size by taking remote areas of the eastern interconnection and equivalizing them into a simple load and gen on one bus representing their system. This has the effect of reducing the overall case size and improves runtime.

The sample size needs to be of significant number to be considered statistically significant to produce a believable average. Typically the confidence interval (CI) is affected by the size of the statistical sample. The larger your sample size the lower the margin of error is. Since the number of possible random generation configurations is infinite a sample size of 100 was chosen based on size and time considerations.

B. Analysis

To create a large amount of random topology cases for analysis purposes Transmission Planning proposed incorporating the Python Coding interface with Siemens PSSE program using the API.
The process steps are outlined below:

1. Choose the amount of Monte Carlo runs (a minimum amount for statistical significance)
2. Identify and solve two benchmark cases to mimic the MISO process (MISO generation assumptions are used to dispatch)
    a. Summer peak (solar 100%)
    b. Shoulder (solar 50%)
3. Choose the random amount of new solar generation to be studied
    a. 69 kV: 3-20 MW
    b. 115-230 kV: 50-100 MW
    c. 345 kV: 200 MW
4. Use Python Code to randomly place solar generation around the NSP and GRE systems up to the amount chosen
    a. Python Code will then readjust MISO system generation down to accommodate the new generation addition. This process chooses generation units that are already on-line to be readjusted down in small increments to prevent the area swing bus from taking the full amount of new generation and thus reducing solving errors.
5. The two new summer and shoulder cases are created with new generation mix
6. ACCC is run on both new created cases
7. A compare is run against output from new cases compared to benchmark cases
8. Thermal overload costs are assigned based on newly created overloads or 3% greater difference than benchmark case
    a. Voltage issue costs were not tracked due to the difficulty in determining validity of identified voltage issues
9. Output thermal overload costs are plotted on scatter graph and a mean is identified for Monte Carlo run

C. Business Benefits

Monte Carlo analysis is used in most other industries to examine probabilistic outcomes using random input variable assumptions. It is heavily used in the finance industry to test financial models over good and bad markets. Traditional transmission planning studies involve a large amount of time in both the model development and the output analysis. Verification of all identified transmission issues and verification of contingencies consume a large amount of time. This type of analysis is typically what is required for reliability projects to comply with NERC standards.

Applying Monte Carlo simulation to the power systems will allow us to test future scenarios over a wide range of inputs and develop likely outcomes. The Monte Carlo approach will not replace the traditional reliability studies currently run to meet NERC criteria, but instead will allow us to develop probabilistic futures for changing generation or load mixes based on future assumptions.

D. Summary

When considering the rapidly changing world related to the power system, Monte Carlo simulations will allow Transmission Planning to develop future probabilistic models to help give insights into future assumptions. This type of random analysis will allow for a large amount of future assumptions to be screened quickly. For the generation example above it can be replicated for any amount of generation, type, or general location.

Future applications for stability are a possibility requiring further examination.

APPENDIX F6 – RESOURCE OPTIONS

I. INTRODUCTION

The main goal of resource planning is to evaluate the size, type, timing and sometimes location of resources we plan to procure to meet customer needs over the next several years. To do this, we take into account key planning considerations, such as carbon reduction goals, reliability, affordability and potential future risk. Over the course of the 2020-2034 planning horizon, our customers' gross peak demand needs are expected to grow from approximately 10,500 MW to just over 11,700 MW, before accounting for Demand Side Management (DSM) adjustments. While we are currently long capacity, a substantial portion of our resources will either reach planned retirement or end of contract dates over the planning period, per our Preferred Plan. As a result, our modeling shows a capacity deficiency in the mid-2020s timeframe. Our Resource Plan addresses how the Company proposes to fill this gap by identifying an appropriate mix of future resource additions.

To identify this mix the Company developed a set of generic resources for inclusion in Strategist modeling, with size, cost, and performance assumptions that reflect updated information from project experience, public stakeholder meeting input, and independent third party studies. Future resource options can be generally categorized as supply-side resources, and demand-side resources. We also evaluated potential transmission cost implications associated with supply-side centralized resources, given current transmission capacity constraints in MISO. Paired with existing owned resources and contracts, this set of generic resources was evaluated in Strategist modeling to determine optimal future resource portfolios, in light of the different scenarios and sensitivities we tested.

II. EXISTING RESOURCES

The Company owns and has under contract approximately 13,500 MW of capacity currently, although as stated above, many of our current resources are slated to retire over the planning period. Below we include discussion of each resource type, and tables showing: each generating unit, whether it is owned or contracted, capacity we own or contract,[1] and the retirement year if known, as reflected in the Strategist model. These numbers have been rounded to the nearest whole number for simplicity, where applicable. It should be noted that the capacity numbers provided below are the maximum values included in the Strategist modeling, and may differ

[1] Expected as of 2020.

marginally from official nameplate or ICAP values.

A. Coal

The Company owns and operates four coal-fired power plants, with a total capacity of 2,390 MW. Planned retirement dates for Sherco 1 in 2026 and Sherco 2 in 2023 were approved in our last Resource Plan, and existing retirement dates for King and Sherco 3 are 2037 and 2040 respectively. As part of our Preferred Plan, we are proposing to retire these two facilities a decade early; where AS King and Sherco 3 would retire in in 2028 and 2030, respectively.

Table 1: Existing Coal Resources

Name of Unit or Contract	Type	Owned or Contracted (PPA)	Capacity (MW)	Existing Retirement/Contract Expiration
Allen S King	Steam Turbine (ST)	Own	511	2037
Sherco 1	ST	Own	680	2026
Sherco 2	ST	Own	682	2023
Sherco 3[2]	ST	Own	517	2040

B. Nuclear

The Company owns and operates three nuclear power plants with a total capacity of 1,738 MW. These units operate at very high capacity factors and provide nearly 30 percent of the energy for our system. They have also both achieved operating costs reductions of over 20 percent from 2015 levels, and both produce energy for our system for under $30/MWh. The existing retirement dates for the nuclear facilities are reflected in the table below. In our Preferred Plan, we propose to extend Monticello plant operation to 2040.

[2] This represents the portion of Sherco 3 under our ownership.

Table 2: Existing Nuclear Resources

Name of Unit or Contract	Type	Owned or Contracted (PPA)	Capacity (MW)	Existing Retirement/Contract Expiration
Monticello	Boiling Water Reactor	Own	646	2030
Prairie Island 1	Pressurized Water Reactor (PWR)	Own	546	2033
Prairie Island 2	PWR	Own	546	2034

C. Natural Gas and Oil

The Company owns or maintains Purchase Power Agreements (PPAs) with many natural gas facilities. Our current natural gas generators are configured as either simple-cycle Combustion Turbines (CTs) or a Combined Cycle Gas Turbine (CCGTs or CCs). The CTs are located at seven different sites and provide peaking capacity meaning they are only typically dispatched a limited number of times a year during peak demand and/or net load conditions. The CCs are located at five sites and provide intermediate capacity, meaning they tend to operate at higher capacity factors due to better efficiencies and lower dispatch prices when compared to CTs.

Our current natural gas and oil fleet provides nearly 4,780 MW of dispatchable capacity. Resource portfolio provides a combined with varying retirement dates In the list of resource below, we provide the capacity and anticipated retirement dates for the Mankato CC assuming we own the resource, per our proposed acquisition in Docket No. IP6949, E002/PA-18-702; however, the Company currently has a PPA for energy and capacity with each of the Mankato CC units. The second unit began commercial operation in June 2019.

Table 3: Existing Natural Gas and Oil Resources

Name of Unit or Contract	Type	Owned or Contracted (PPA)	Capacity	Existing or Planned Retirement/Contract Expiration
Black Dog 52	CC	Own	298	2032
High Bridge	CC	Own	606	2048
Riverside	CC	Own	508	2049
Mankato Energy Center[3]	CC	Own	762	2046, 2054
LSP – Cottage Grove	CC	PPA	245	2027
Angus Anson 2-4	CT	Own	386	2034
Black Dog 6	CT	Own	232	2058
Blue Lake 7,8	CT	Own	351	2034
Inver Hills 1-6	CT	Own	369	2026
Wheaton 1-4	CT	Own	241	2025
Cannon Falls Energy Center	CT	PPA	358	2025
Blue Lake 1-4	Oil	Own	191	2023
French Island 3,4	Oil	Own	160	2027
Wheaton 6	Oil	Own	70	2025

D. Biomass

The company owns and operates, and maintains PPAs with, various biomass facilities. Refuse-derived fuel (RDF), landfill (LND) and digester (DIGT) resources are also generally considered biomass resources and therefore included in this category. These facilities total nearly 160 MW of capacity on our system.

[3] Note: As stated above, we have modeled Mankato Energy Center as an owned resource. Approval of this acquisition is pending in Docket No. IP6949, E002/PA-18-702.

Table 4: Existing Biomass Resources

E. Hydroelectric

The Company owns, operates and maintains PPAs for hydropower resources with a number of different counterparties, totaling over 680 MW. The majority of our current hydro capacity is provided by our PPAs with Manitoba Hydro, which expire in 2025. We also have an additional 125 MW PPA with Manitoba Hydro that is slated to start in 2021. Further, the Company has a 350 MW Diversity Agreement with Manitoba Hydro, wherein we receive 350 MW of capacity in the summer and Manitoba Hydro receives 350 MW of capacity in the winter. Due to the unique nature of the agreement, it is not included in the list below or reflected in the total hydro capacity specified above.

[4] Note: This unit is included in Strategist modeling, but its PPA was terminated as of April 2019.

F. Wind

The Company owns or contracts for over 2,600 MW of wind power. Over the next two to three years, the Company intends to add 1,850 MW of wind generation from recent acquisitions and Requests for Proposal (RFPs), as well additional capacity to serve other customer programs.

G. Solar

By 2020 the Company anticipates it will maintain a total of 990 MW of solar capacity, via PPA, to serve our customers. This includes approximately 260 MW of large grid-scale solar, over 640 MW of Community Solar Gardens (anticipated by 2020), and nearly 90 MW of small-scale distributed solar.

III. GENERIC FUTURE RESOURCE OPTIONS

Consistent with past resource plans, we have developed generically-defined resources to use in Strategist modeling, from which the model can select when resource retirements or PPA expirations result in our remaining portfolio falling short of future projected demand. Cost and performance data for these resources was developed using a mix of third party studies and forecasts such as the National Renewable Energy Laboratory (NREL) Annual Technology Baseline (ATB), consultant estimates, and internal Company data. Generic resources are intended to help identify the general size, type, and timing of resource needs in the future and do not typically represent a specific resource at a specific location, or whether such a resource would be owned or contracted. Rather, these specific details are determined via a competitive acquisition process that is held after the general size, type and timing has been established and approved in the Resource Plan proceeding.

[7] Includes Solar*Rewards and Made in MN Solar

It is important to highlight that the Company worked closely with and solicited feedback from stakeholders to select the best sources and methodologies to employ in developing generic resource options. Our stakeholder interactions, and direction from our regulators, resulted in a number of refinements to our past assumptions. We believe these adjustments improved the quality of our modeling and highlight the benefit of our proactive approach to stakeholder engagement.

A. Supply Side Resources

Supply-side centralized resources are traditional large-scale thermal and renewable generation facilities. We have included a number of supply-side centralized fuel types in our modeling; large-scale wind and solar, a variety of natural gas resource options, and battery energy storage. Their attributes, and the method by which we developed each one, are described further. We also detail specific resource cost and performance assumptions in Appendix F2, unless otherwise noted.

1. Wind

Our generic wind resource option was sized at 750 MW on nameplate capacity basis. While the size of this generic wind resource may seem relatively large, we account for the MISO accredited capacity value for new wind resources as 15.6 percent[8] of this total, or about 117 MW. Given our modeling selects resources on the basis of their accredited capacity, and given the size of our system, and magnitude of future capacity needs, we feel this sizing represents an appropriate approach to modeling generic wind additions.

We derived forecasted wind costs used in our modeling from publicly available data from the NREL 2018 ATB Levelized Cost of Electricity (LCOE) data. This cost has been further adjusted for tax credit effects in relevant years, and converted to nominal dollar terms. We have also added estimated transmission costs associated with a greenfield generation facility, as described further below.

2. Solar

Our generic supply-side large-scale solar resource is sized at 500 MW on a nameplate capacity basis. Similar to wind resources, it is important to note that the MISO accredited capacity value for solar is discounted by 50 percent, thus the Strategist model considers generic solar additions in 250 MW firm capacity increments. This

[8] Reflecting the wind capacity accreditation value for Planning Year 2018/2019.

accredited capacity size increment is comparable to other generic resource assumptions, and thus evaluating solar in this size increment is appropriate. We derived forecasted solar costs from the publicly available LCOE data in the NREL ATB as well. Similar to the adjustments for wind resources, this cost has been adjusted for tax credit impacts in the relevant years, and converted to nominal dollar terms. We have also added estimated transmission costs associated with greenfield generation facilities, as described further below.

Our modeling also includes a forecast of distributed solar adoption, applied as a supply-side resource with an assumed adoption rate. In addition to these static forecasts, we had planned to include distributed residential and commercial solar as generic resource options in the modeling. However, we ultimately found these resources would not be selected by the model and eliminated them from the optimization exercise. We feel this is justified, as generic distributed solar continues to be significantly more expensive, on a levelized cost of energy (LCOE) basis, than large-scale solar. This cost delta exists even when including transmission costs for large-scale solar, and as a result, it would be highly unlikely that distributed solar would be selected in our scenario optimizations where the model could choose less expensive large scale solar instead. Therefore, to improve model runtimes and reduce truncation issues, as discussed in Chapter 4: Preferred Plan, distributed solar was included at an assumed adoption rate and not further optimized in the Strategist model.

Please see Appendix F1 for more information regarding distributed solar forecasts.

3. Natural Gas

We have included three potential generic resource configurations for natural gas, given the different types of generator and location types. Specifically, we have included options for both CT and CC generic units. Based on our pre-screening review of cost and performance data available from major equipment suppliers and construction contractors, we developed generic resource options based on those we felt had the best economic viability in our system.

For CTs we developed two generic options, differing in size, configuration, and whether the site would be green- or brown-field, based on the available external data noted above and internal engineering assessments. For CCs, we developed one generic option, and applied similar methods to identify appropriate generator cost and performance assumptions from external sources and internal engineering assessments. Here, however, we depended upon an external consultant analysis to better understand potential interconnection costs across several greenfield sites, given

increased complexity of siting a several hundred MW gas generation unit and navigating the current MISO generator interconnection process.

4. Battery Energy Storage

For the first time in this IRP process, we have developed a generic four-hour battery energy storage resource to include in our Strategist modeling. The unit is sized at 331 MW, which we selected based on both our understanding of our system's future capacity needs and to ensure size parity with one of our generic CT options. Our resource cost assumptions are based on bids our Public Service Company of Colorado operating company received in response to a late 2017 all-source solicitation. To forecast future costs, we applied NREL ATB estimated technology learning curves to these internal cost estimates. For more discussion on storage, see the Minnesota Energy Storage Assessment in Appendix F7.

B. Demand Side Management (DSM)

Based on external studies and stakeholder feedback, we have updated our approach to modeling DSM resources in this Resource Plan, as compared to past years. The Company utilized a *Demand Response Potential Study* provided by the Brattle Group (Appendix G2) and a *Minnesota Energy Efficiency Potential Study*[9] prepared for the Minnesota Department of Commerce, Division of Energy Resources to convert DSM resources into supply-side option "Bundles," which could compete against other resource alternatives in Strategist modeling. Our approach to developing Bundles from the information provided in the study is described below.

1. Energy Efficiency (EE)

Based on external studies and internal expertise, the company developed three Bundles, termed Program, Optimal, and Maximum. Internal experts provided detailed cost, and energy and demand avoidance characteristics, for the three Bundles by year. Each Bundle is included in Strategist as a supply-side resource the model could potentially select. The Program and Maximum Bundles are based on the 2018 *Minnesota Energy Efficiency Potential Study* findings. The Optimal Bundle was developed by the Company using the study results for optimal demand reduction (as opposed to energy reduction). Each Bundle included in our resource modeling is incremental to the last, and selection of any Bundle is dependent on the Bundle before it being

[9] Study available at: https://www.mncee.org/MNCEE/media/PDFs/MN-Potential-Study_Final-Report_Publication-Date_2018-12-04.pdf

selected (i.e. Bundle 2 cannot be selected if Bundle 1 is not selected).

2. Demand Response (DR)

Similar to the process for EE, we developed Demand Response (DR) Bundles, so that DR could be treated as a supply-side resource in the Strategist modeling. Consistent with past practice, the Company developed a Base DR Forecast from existing programs, which was included in all baseline resource modeling. The Company then developed three DR Bundles incremental to the Base DR Forecast, based on the Brattle Study noted above. The DR Bundles were designed by taking a point-in-time supply curve of DR options in the study, and developing more detailed annual demand reduction and cost characteristics by year. The Bundles were generally sized to account for supply curve price thresholds, with Bundle 1 achieving demand reduction of 270 to 542 MW; Bundle 2 achieving an incremental 107 to 242 MW; and Bundle 3 achieving an incremental 89 to 112 MW during the planning period. Similar to EE, the DR Bundles are incremental to each other and dependent on the preceding Bundle being selected (i.e. Bundle 2 cannot be selected if Bundle 1 isn't selected).

C. Transmission Costs for Greenfield Resources

In addition to generating resource assumptions, our Strategist modeling also includes transmission cost considerations for new greenfield resources. These values are intended to capture the transmission expansion and/or interconnection costs required to successfully integrate new greenfield resources into the system. Given current challenges with the MISO interconnection process, and shrinking available transmission capacity on the system, significant study delays and major upgrade costs are likely to result in elevated transmission costs for future resources. Therefore, the Company engaged in a number of internal and external studies in order to appropriately represent anticipated transmission costs associated with new greenfield CT, CC, wind and solar resources. To assess CC transmission delivery costs, the Company hired Excel Engineering, a third party consultant, to perform a study that evaluated potential costs for six different locations on the system. The study identified the potential for high interconnection costs at all of the potential site locations, ranging from a low of $263 million to a high of $1,354 million. Cost levels in this study are dependent in part on the percentage of planned projects that withdraw from the MISO queue. Excel Engineering's Interconnection Cost Estimates is included in Appendix R.

To assess wind and solar transmission delivery costs, the Company's internal Transmission Planning Group performed a random placement technique study. This study identified and solved two benchmark cases to mimic the MISO process. Next,

new solar capacity was added at random locations, in order to study the modeled effect on the transmission system. These results were then compared back to the "benchmark" study, to help identify transmission system violations. Finally, interconnection cost estimates were developed by estimating the costs necessary to remedy the violations identified in the study. This methodology is further explained in Appendix F5.

IV. POTENTIAL RESOURCES NOT CONSIDERED IN MODELING

The Company considered several additional technologies in the initial screening process that, in the end, were not included in modeling. We discuss these resources and why they were not included below. We will continue to monitor and screen these options for possible inclusion in future Resource Plans, and/or allow them to compete in future competitive resource acquisition processes, in order to gain additional information on their potential costs and operating characteristics.

A. Biomass

New biomass resources were excluded from consideration as generic options, primarily due to cost. Generic estimates for biomass resources from the U.S. Energy Information Administration (EIA), and other sources, indicate that the capital costs of biomass resources are substantially higher than those associated with generic wind, solar, and natural gas resource options. As a result, the Company did not include a generic biomass resource for consideration in the modeling.

We anticipate, however, that future acquisition processes may allow biomass resources to compete in resource solicitations. There are also existing biomass resources in our region that may be available to help meet our future resource needs. If found to be cost competitive, they could be selected to displace other generic options identified in our Plan.

B. Combined Heat and Power (CHP)

CHP was not included as a generic resource option, as studies indicated it will have limited economic potential during the planning period. The Company engaged the Electric Power Research Institute (EPRI) and ICF International to evaluate the technical and economic potential for CHP applications in our Minnesota service area. The study estimates a total of 319 MW of technical potential from 239 sites and 145 MW of economic CHP potential in Xcel Energy's Minnesota service territory. Under the base scenario, CHP adoption is estimated at 43 MW through 2039. We provide the study as Appendix S.

C. Nuclear

Nuclear is an important, reliable resource that helps contribute to our carbon-free portfolio. There are a number of existing and new nuclear technologies currently being considered for future deployment; however, while these technologies appear promising, there remain commercial barriers to adoption such that we did not include them as generic resource options for our plan. Outstanding commercial uncertainties include:

- Technological maturity and component manufacturing experience
- Risks and costs related to construction delays and/or budget overruns
- Options for disposal of spent nuclear fuel from new facilities
- State and federal regulatory barriers or uncertainty

Of note, Minnesota state statute currently prohibits the Commission from issuing a Certificate of Need for the construction of a new nuclear facility.[10] We further discuss emerging nuclear technologies in Section V below.

D. Pumped Hydro

Pumped hydro is a mature flexible-duration storage technology with a relatively long operational life; however, environmental challenges and resource economics have generally limited its growth. Further, pumped hydro unit configurations and costs are highly site specific, which makes it a difficult resource to represent generically. As a result, the Company did not include a generic pumped hydro resource for consideration in modeling. Similar to biomass resources, the Company remains willing to evaluate pumped hydro projects in future resource solicitations, and if cost effective, pumped hydro resources could displace generic resource options identified in this Plan.

E. Coal

New generic coal resources were eliminated from the list of resource options due to cost, environmental challenges, and non-alignment with our strategic goals. Capital costs for generic coal resources are high relative to new gas and renewable resource options. Low natural gas prices, increased renewable penetration, and regulatory risk

[10] Laws of Minnesota 1994, Chapter 641, Article 2, Section 1, Subd. 3b.

create additional challenges and major risks for new coal resources. Furthermore, adding coal resources with high carbon emission levels would not align with our commitment to deep carbon reduction on our electric system. For these reasons, we have excluded new coal resources from our modeling. While the Company will continue to monitor carbon capture and sequestration technology developments, we do not expect to consider new coal resources in future resource plans.

V. EMERGING TECHNOLOGIES

As we have previously stated, we can achieve our 2030 carbon reduction goals with existing technologies; however, achieving our vision of a carbon-free electricity supply by 2050 will require significant technology developments that either do not yet exist or are not yet commercialized. In particular, our system will need stable baseload and dispatchable carbon-free generation, and energy storage technologies that can help us maintain reliability for every hour of every day while also keeping our electricity affordable for customers. We are continually assessing new technologies that may be viable options for future resource planning cycles. Below we present a non-exhaustive list of example technologies we are currently tracking.

A. Allam Cycle Application for Emissions Capture in Natural Gas Plants

The Allam Cycle uses natural gas to produce power, but in a different fuel burning process than traditional CTs. Instead of using ambient air for combustion directly, the plants burn natural gas with pure oxygen generated within an Air Separation Unit. This "oxy-combustion" produces CO2, which is then used in the plant's electricity generation process. Using pure oxygen rather than ambient air eliminates nitrogen oxide emissions from the plant's process. The CO_2 released from the combusted natural gas is captured within the plant's process and reused to support additional cycles of fuel combustion. Heat energy is also recovered and used in the process. Excess CO_2 not needed for energy generation can be stored or used in other industrial processes.

NET Power, a company working to commercialize this technology, has recently finished a demonstration project in Texas that is providing power to local customers and undergoing testing to connect to the broader transmission system. They are also working to develop a larger commercial facility with Occidental Petroleum.[11] While this technology remains more expensive than conventional gas plants, we will

[11] *See* Patel, Sonal. "Insite NET Power: Gas Power Goes Super-critical." Power Mag (April 2019). Available at: https://www.powermag.com/inside-net-power-gas-power-goes-supercritical/

continue to monitor this and other potential developments in carbon capture and storage for potential future application in our system.

B. Hydrogen for Power Generation

Hydrogen is another fuel with potential to support dispatchable carbon-free generation as burning hydrogen, by itself, does not produce any carbon emissions. In existing applications; however, hydrogen is typically mixed with natural gas, which has the effect of lowering a plant's CO_2 emissions levels. Introducing hydrogen into the fuel mix for an existing gas plant does not always require substantial plant retrofits. In fact, some conventional gas turbines are already capable of burning hydrogen in low-to-medium concentrations. For higher concentrations, more significant plant configuration changes are likely required.[12]

There are several methods of producing the hydrogen that would be burned in these units, from using existing industrial process byproduct hydrogen to producing it in dedicated water electrolysis facilities. Current methods like water electrolysis are, in themselves, energy intensive, and as such can make using hydrogen for electricity generation expensive. As the share of variable renewables on the electric grid increases, however, these processes may be able to use inexpensive (or negative priced) excess energy in some hours of the day to reduce the cost of producing the hydrogen. In this sense, hydrogen derived from renewable energy serves as a long duration storage option, where the fuel can be stored over days, weeks or months until needed and burned in a dispatchable plant without any carbon emissions.[13]

Pilot projects in Germany and Denmark, for example, are currently testing using excess wind generation to produce hydrogen through electrolysis[14] that can then be used as needed in a retrofitted natural gas generation plant. Various companies, including leading CT suppliers and startups, are working to further develop and commercialize both the turbines that can run on higher levels of hydrogen and the electrolysis facilities that would produce hydrogen using excess clean energy. We continue to monitor technology progress in the hydrogen space, to evaluate the

potential for our gas generation assets to convert to hydrogen use in the future. We are also exploring ways to use electricity generated from our nuclear units to generate hydrogen through on-site electrolysis.

C. Emerging Nuclear Technologies

Nuclear power is one of the most reliable and lowest operating cost resources we have in our system. Our two nuclear plants provide nearly 30 percent of our electricity mix, carbon-free and at a cost (fuel and O&M) below $30/MWh. However, it is increasingly difficult to build new conventional nuclear units, in part due to their typical scale and associated high upfront costs.

Substantial industry research into several advanced nuclear technologies is ongoing. For example, in recent years there have been renewed efforts to develop advanced reactors that use sodium, gas or liquid metals in place of traditional cooling materials. Renewed research is also ongoing into applications wherein the nuclear fuel itself can be dissolved into molten salt, in order to operate at lower pressures than traditional pressurized water reactors. Using molten salt in this way is intended to improve safety considerations. Some advanced reactor designs are intended to reduce spent fuel volumes, by either enabling longer durations between refueling events or instituting closed fuel cycles that reprocess and reuse spent fuel within the reactor. Reducing spent fuel volumes can both reduce fuel costs and mitigate spent fuel storage challenges. Some designs also incorporate passive safety designs through natural convection cooling.

Other developers are researching potential application of light water reactor technology to small modular reactors (SMR). SMRs would be intended to be more flexible, able to serve smaller scale needs, and allow reduced backup infrastructure, as compared to existing nuclear units. This general concept is already used in military applications and for marine vessels that need to go long periods between refueling. SMRs are typically less than 300 MW in size and factory fabricated in modular units. The modular design is intended to enable streamlined production, shipping, and installation processes, in order to help manage costs. Further, the units are intended to go longer in between refueling outages than conventional plants, and allow refueling of one unit as the others continue to operate.[15] As an emerging technology, however, it is not yet clear whether SMR costs will be competitive with other sources of energy.

[15] *See* "Benefits." NuScale Power. Available at: https://www.nuscalepower.com/benefits

Several companies are currently working through NRC licensing processes for emerging nuclear technology, with the goal of attaining design approval for their advanced and small modular reactors by the mid-2020s, in order to complete pilot plants in the late 2020s.

D. Energy Storage Advancements

Large scale battery energy storage is increasing its presence on the grid, being used to integrate renewables, defer grid investments, and more. In fact, the Company has had a sodium-sulfur battery operating on the NSP System since 2009, in order to gain valuable technology experience.[16] Many batteries installed today use lithium-ion (li-ion) chemistries, benefitting from economies of scale gained in consumer electronics and, to some extent, electric vehicle manufacturing. Grid-scale li-ion batteries typically store energy for relatively short durations, providing a few hours of capacity or energy services.[17] While these shorter duration batteries hold great promise to mitigate demand peaks or short periods of intermittency now, in the long term with higher renewable penetration, the grid will need a combination of short and longer duration storage capabilities to effectively match variable renewable output to customer load. Further, costs for short and longer duration storage will need to decline further for energy storage to be deployed at scale.

To this end, there are several emerging storage applications that either use different chemical and physical properties, with the goal of mitigating cost and/or duration challenges. A few examples of emerging energy storage technologies we follow include:

- **Solid state li-ion batteries**: Current li-ion batteries, while continuing to become more cost effective for stationary storage applications, use a liquid electrolyte that has room to improve in terms of energy density. Development is underway that would replace the liquid electrolyte with solid materials, that offer higher energy densities and reduce potential for leakage and flammability. Solid state batteries hold promise to reduce the cost of energy storage, because increasing energy density allows more energy to be stored for discharge when needed. They also hold promise in increasing the number of times the battery can cycle before requiring material replacement.[18] These batteries are not yet

[16] The Luverne MinnWind Storage Project is a 1 MW, 7MW-h sodium sulfur (NaS) battery paired with an 11 MW wind facility in western Minnesota.
[17] As noted above, our modeling included a 4-hour duration generic battery energy storage option, which we believe is in line with most commercialized grid-scale lithium ion batteries installed currently.
[18] Tohoku University. "Highest energy density all-solid-state batteries now possible." ScienceDaily. (March

commercially available, but there is substantial interest in continuing development. Large industrials – such as Samsung, Hyundai, and Solvay – and venture funds such as Breakthrough Energy have invested in startups developing the technology.[19]

- **Flow batteries**: Flow batteries are a category of technology that includes several types of chemistry compositions. While not a new technology in general, application to stationary power system remains relatively nascent. In general, flow batteries are a cross between a conventional battery and a fuel cell, where a liquid electrolyte cycles through a core, and ion transfers between the cathode and anode generates electricity. As such, flow batteries tend to have favorable life cycles and may provide longer duration storage than li-ion designs; as the electrolytes are separate from the cell itself, the tanks can be scaled up without also scaling up the cell. However, round trip efficiency can be lower than in lithium-ion batteries, and this application has not been proven to serve substantially longer durations than lithium-ion.[20] [21] San Diego Gas & Electric, a utility in California, has recently installed a flow battery to its grid for a four year pilot project, where it will evaluate battery economics, renewable integration, and wholesale market services potential.[22]
- **Electrothermal energy storage**: Thermal storage for renewables has been implemented in limited use cases. There are, for example, existing large scale solar thermal facilities in the desert southwest that use large tanks of molten to store energy in the form of heat, across several hours or even days, until needed. This concept has not traditionally been applied to solar PV or wind facilities; however, a company called Malta is working to develop Carnot batteries (i.e. pumped thermal storage) that could be deployed either at greenfield or brownfield locations. Their concept converts the electricity from a solar PV or wind facility into thermal energy through a heat pump. Heat can be stored in molten salt while cold is stored in a chilled liquid. To discharge the energy, transfer fluid is run through both the hot and cold storage tanks, creating steam that can be used to convert the energy back into electricity. This

system is intended to provide longer duration storage, with a longer facility life and at lower capital cost than a typical battery storage facility.[23] In Germany, Malta and other partners are working to develop a pilot project on a brownfield coal site, in order to repurpose the steam turbine to generate electricity from the stored renewable energy.[24]

- **Subsurface pumped hydro storage**: Pumped hydro storage has been the primary method of long duration storage on the grid for many years, including the Company's own Cabin Creek pumped hydro facility in the Colorado service area. As noted above, however, we have not included it in our generic resource modeling due to dependence on specific geologic structures and related challenges in estimating generic costs. There are, however, companies working to provide scalable pumped hydro solutions that can be built in areas without the typical geologic structures. For example, a company called Quidnet is proposing to use conventional reservoir technology and typical oil and gas well practices to create subterranean compressed hydro storage facilities. To store energy, water would be pumped down into an underground well and held under pressure in the rock formation. When energy is needed, the pressure would be released and the water would flow through a conventional hydro turbine to generate electricity. This system is intended to be closed loop, to conserve water. The necessary underground rock structures are also more ubiquitous, and the plants can be more flexible in scale than conventional pumped hydro storage.[25]

APPENDIX F7 – MINNESOTA ENERGY STORAGE SYSTEMS ASSESSMENT

I. INTRODUCTION

In the 2019 legislative session in Minnesota, there was legislation passed as a part of the jobs, economic development, energy, and commerce omnibus bill amending Minnesota Statutes 2018, section 216B.2422 to require utilities to include an assessment of energy storage systems in their resource plan filing. The full text of the legislation is included below:

> Subd. 7.**Energy storage systems assessment.**(a) Each public utility required to file a resource plan under subdivision 2 must include in the filing an assessment of energy storage systems that analyzes how the deployment of energy storage systems contributes to:
> (1) meeting identified generation and capacity needs; and
> (2) evaluating ancillary services.
> (b) The assessment must employ appropriate modeling methods to enable the analysis required in paragraph (a).
> **EFFECTIVE DATE.** This section is effective the day following final enactment.

In this Appendix, we include background on Xcel Energy's growing experience with energy storage technologies, a narrative on the values that storage can provide to the system, some of the shortcomings of current storage technologies, and how we analyzed energy storage as a part of this Resource Plan.

Xcel Energy's long-term carbon strategy depends on the deployment of advanced clean technologies. We expect grid-scale energy storage to play an important role in our long-term plans. While we do not anticipate significant reliance on battery storage resources in this plan for the Upper Midwest in the near term, we are piloting storage technology across our system to test the capabilities, and will look for opportunities for more aggressive deployment of these resources in the future as we have generation capacity needs.

As discussed in more detail below, grid-scale storage can help integrate increasing levels of renewable resources. Storage can also provide other system benefits, including more reliable grid operations, voltage support, and frequency control. Utilities are already taking advantage of many different values of grid-scale storage. In fact, utilities are the leading developers of storage technology in the nation. As grid owners and operators, utilities are uniquely situated to maximize the potential benefits of storage. As detailed further in this Appendix, Xcel Energy has a number of advanced storage projects already deployed on our system and a growing interest in using storage in the future.

At the same time, we recognize that storage today has limitations. We discuss here three significant challenges for storage: First, storage cannot today solve the problem of the wide seasonal variation in renewable energy generation, which is the chief factor preventing the creation of fully renewable electricity system. Second, while storage can initially help integrate renewables by moving energy from the time it is produced to when it is needed, the value of each additional increment of storage capacity declines as more is added to the system. Finally, although storage can provide multiple services to the grid – power quality and grid support, for example – the value of all of these services are not all additive (or "stackable"). As a general rule, these services are not all available at the same time. Despite these limitations, we are bullish on the potential of storage as a part of our electricity system.

II. XCEL ENERGY'S ENERGY STORAGE EXPERIENCE

Electricity storage devices include a variety of technologies that store electrical energy directly (e.g. capacitors) or, more typically, after converting to some other form of potential or kinetic energy. For example, pumped hydro storage facilities use electrical energy to pump water to a higher elevation and store that water as gravitational potential energy; flywheels use electrical energy to rotate a mass to high velocities and thus store energy as kinetic energy; compressed air projects store energy in a geologic formation as pressurized potential energy; and batteries use electrical energy to drive chemical reactions and then store that energy as chemical potential energy. As no energy conversion process occurs without inefficiencies or losses, any energy storage system will discharge a lesser amount of energy than used to charge the device. If deployed properly, energy storage can help enable a smarter, stronger, cleaner and more reliable grid.

Xcel Energy has long been a leader in deploying energy storage. We have operated pumped hydro energy storage on our system for decades and have adapted its operation to meet our evolving system. Today, we are implementing pilots and other programs exploring new storage technologies that will play a role in our energy future.

A. Cabin Creek Pumped Storage

Historically, pumped storage hydro has been the dominant source of energy storage – even today, nearly 92 percent of operational storage in the US is pumped storage. Our largest energy storage asset is the 324 MW Cabin Creek pumped hydroelectric storage facility in Colorado. The Cabin Creek facility was built in 1967. Like all pumped storage facilities, it has an upper and a lower reservoir. When economic, we pump water from the lower to the upper reservoir. When the system has additional

energy needs, we allow the water to "spill" out of the upper reservoir to the lower through a hydro turbine to generate electricity. Originally, the facility was used to transfer excess energy from off-peak hours to on-peak hours, but today it is also used for renewable energy integration. We spill water to meet customer demand when the wind stops blowing and pump water to the upper reservoir during times when the wind energy generated on our system exceeds customer demands.

B. Luverne MinnWind Storage Project

The Luverne wind-to-battery project in Minnesota was one of the first battery storage pilot projects the Company pursued and the first U.S.-based pairing of wind energy and a storage battery. The pilot was intended to test the various ways batteries could be used to provide wind integration and regulation services supporting the energy grid. The 1 MW, 7 MWh sodium sulfur battery paired with an 11 MW wind project has been in-service since 2009, and was recently updated by the manufacturer with new grounding technology and cells, extending the life of the battery and allowing us to test new battery applications. It was funded in part by a $1 million grant from Minnesota's Renewable Development Fund.[1]

C. SolarTAC

We are the original founding member, host utility and a development partner at the Solar Technology Acceleration Center (SolarTAC), an outdoor solar testing facility located in Aurora, Colorado.[2] Together, the solar industry and utilities work at SolarTAC to test, validate and demonstrate advanced solar technologies under actual field conditions. We worked with our SolarTAC partners to test two different battery storage projects.

- A community energy storage project at SolarTAC is testing a more cost-effective way to improve the integration of solar power in areas with high solar production. Working with the Electric Power Research Institute (EPRI), we are testing a 25-kilowatt battery integrated with four small photovoltaic installations that simulate a neighborhood with multiple rooftop solar power systems.
- Through our Solar2Battery project, we installed a 1.5 MW battery to evaluate how energy storage can help in operating the electricity grid with energy from large-scale solar facilities.

[1] Xcel Energy Wind-to-Battery Project: https://www.xcelenergy.com/staticfiles/xe/Corporate/Environment/wind-to-battery%20fact%20sheet.pdf
[2] Solar Technology Acceleration Center: http://www.solartac.org/

These projects have increased our knowledge of how batteries respond to intermittent solar generation, how battery chemistries perform over time, and how energy storage systems can create value for our system.

D. Innovative Clean Technologies Program

The Colorado Public Utilities Commission has approved an Innovative Clean Technologies (ICT) program to test emerging technologies that are designed to lower carbon emissions associated with electricity service. We currently have two battery storage demonstration projects operating under the ICT program:

- Stapleton Community Energy Storage Project: As demand for solar energy at our customers' homes and businesses increases, we are examining how battery storage can help integrate higher concentrations of customer solar energy on our system. Through a project in Denver's Stapleton neighborhood, Xcel Energy installed six customer batteries and six larger grid batteries to test rooftop solar integration and grid support capabilities.[3]
- Panasonic Battery Demonstration Project: Through a public-private partnership, Xcel Energy, Panasonic and Denver International Airport are collaborating to test a battery storage system that can both serve as a microgrid to provide backup power to Panasonic's Denver headquarters and support Xcel Energy's grid at other times. As part of the project, Xcel Energy owns a 1.3 MW solar carport installation and a 1 MW/2MWh lithium ion battery. Panasonic also owns a 0.20 MW solar array located atop its building, which is also tied into the system.[4]

E. Fort McCoy Solar plus Battery Microgrid Partnership Project

We are partnering with Fort McCoy, a U.S. Army installation in Wisconsin, to develop a solar-plus-storage microgrid demonstration project to provide a secure source of power to certain critical facilities on the Army Base. The project will combine onsite solar photovoltaic generation with energy storage to provide additional resilience to support identified facilities through a microgrid in an extended outage, likely in combination with existing backup generation.

[3] Community Storage Project in Stapleton Neighborhood: https://www.xcelenergy.com/energy_portfolio/innovation/stapleton
[4] Panasonic Battery Demonstration Project: https://www.xcelenergy.com/staticfiles/xe-responsive/Energy%20Portfolio/CO-Panasonic-Fact-Sheet.pdf

Through this project, the Company will gain a solar resource to supply energy to its customers, as well as experience with operating and maintaining a solar-plus-battery microgrid and optimizing the use of these resources. We will also gain experience valuable to understanding the performance of these systems, applicability and implementation of new MISO rules for battery storage participating in MISO markets, as well as knowledge and insight that will enhance our ability to understand, plan for and accommodate future battery storage applications. We anticipate this project will be operational in 2021.

These pilot projects have provided operational experience for future, widespread deployment of batteries on our system. From these projects, we have gained detailed information on the value, costs and benefits of battery installations. The projects demonstrate the need for better interoperability between the devices and systems. They will inform future system architecture, including cybersecurity and interconnection issues associated with battery operation. In addition, we currently have nearly 300 residential batteries installed across our states and are working with customers and the storage industry to provide battery interconnection guidelines and support. The legislation passed in Minnesota in 2019 also allows for cost recovery of energy storage system pilot projects.

F. Colorado Energy Plan

The Colorado Energy Plan (CEP) is the next step in our efforts to transform our energy system for our Colorado affiliate. It includes the retirement of two existing coal units and the construction of 1,100 MWs of new wind and 700 MWs of new solar. As part of the all-source bids associated with the CEP, we received 133 total energy storage bids from 97 separate projects. Taking advantage of the tax credit incentives, several of the project developers were able to present us with competitive pricing for batteries paired with solar. From these bids, we selected two separate battery-plus-solar projects totaling over 600 MWs of universal scale solar paired with 275 MWs of battery storage, which was then the largest utility-proposed acquisitions of battery storage in the U.S. The Colorado Public Utilities Commission approved CEP in August 2018, and with this approval we are moving forward to implementation.

III. ENERGY STORAGE VALUES

Energy storage can be deployed in all parts of the energy grid, and can help to enable a smarter, stronger, cleaner, and more reliable energy grid for our customers. There are multiple opportunities for energy storage to add value to our system. We focus

here on four key areas: renewable integration, grid support, deferred investment, and power quality.

A. Renewable Energy Integration

As Xcel Energy continues to add significant amounts of renewable energy generation to our system, energy storage can support integrating those renewables into the energy grid. Renewable energy is available when the wind blows or the sun shines, and customer energy demand is often not synchronized with its availability. Storage can help shift renewable energy to time periods when it is needed, reducing the need for investment in peaking plants and support facilities. This is especially true for short-term deviations – a few minutes to a few hours – between customer demand and renewable generation.

B. Grid Support

As the owners and operators of the grid, utilities are first and foremost responsible for the safety, reliability, and optimal operation of our system for our customers. A reliable electric system requires attention to the physics of electricity transmission and distribution. It is not enough to match generation and power supply; we also must make sure that the power can be delivered to customers. Energy storage can help with grid reliability and resilience by providing:

- voltage support at critical places on the electric system where low voltage prevents the transmission of power;
- ancillary services such as:
    - frequency regulation – ensuring that the appropriate frequency of the alternating current on the system is maintained
    - spinning reserves – available resources to increase power output to meet fast changes in demand
    - operating reserves – resources to make up the difference between production and demand when production is low
- energy arbitrage, purchasing and storing electricity during off-peak times, and then utilizing that stored power during periods when electricity prices are the highest;
- readily available reserves, reducing the need for additional investments in "quick start" generation and transmission assets that maintain the system in the event of a disruption; and

- Black start capability, or the ability to restart the entire electric system in the event the whole system goes down.

Utilities are well-positioned to maximize the value of these storage capabilities to ensure system planning and visibility with the primary objective of enhancing reliability and optimizing performance in a cost-effective manner. We can facilitate the deployment of energy storage on our system when and where it is most needed.

C. Deferred Investment

Storage has the potential to take the place of traditional grid investments across our system, including investments in peaking generation, transmission and distribution upgrades, and reliability investments to maintain grid support. Its ability to do so depends on whether the proposed storage resource is (1) capable of providing the same benefits as the asset it replaces; (2) cheaper than the more traditional alternative; and (3) has some level of visibility and control by the grid operator. As storage technologies continue to improve and prices come down, there are greater opportunities for storage to take the place of existing technologies, especially in areas where the unique circumstances of the system make traditional technologies more expensive.

We are actively exploring additional deferral opportunities for our system where storage may provide a solution. This requires new tools and processes to analyze the appropriate location and size of the potential storage solution, as well as a cost-benefit analysis of those solutions as compared to traditional grid investments. Properly positioned storage can defer or reduce the need for incremental transmission and distribution investments, while poorly-sited storage may require additional investments in new capacity or distribution upgrades.

D. Power quality

Some of our customers seek power quality above and beyond what is provided by our standard electric service. Batteries can improve power quality by helping avoid the momentary outages that interfere with the operation of sensitive electronic equipment. Projects like our Panasonic pilot have demonstrated the value of customer-utility partnerships in addressing these issues by placing a utility-owned battery close to, or at, a customer site to provide premium power quality service, while also allowing the utility to leverage the battery for grid services.

We are optimistic about these and other benefits of grid-scale storage. Key to capturing the full spectrum of these benefits is the recognition that storage is first and

foremost a grid asset. As more and more energy storage is deployed on our system and across the country, it is important that the rules governing ownership and operation of energy storage assets are clear and aimed at maximizing the grid benefits of storage while encouraging its affordable, reliable and safe deployment. Utilities are uniquely situated to understand the grid and its needs and should play an important role both in owning and operating grid-scale storage.

IV. CHALLENGES OF CURRENT ENERGY STORAGE TECHNOLOGY

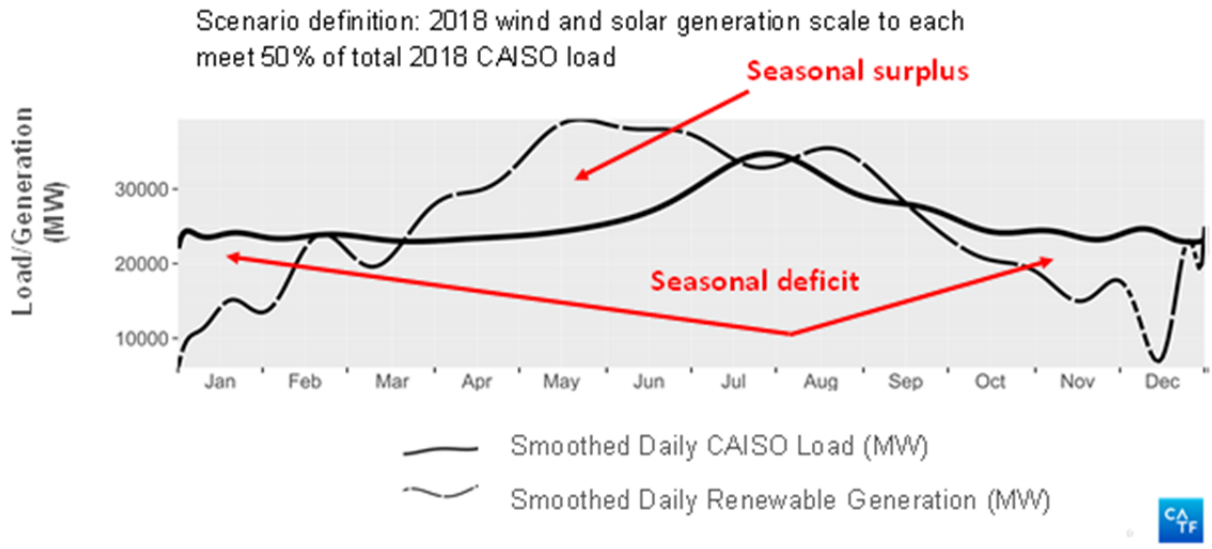
Energy storage offers opportunities to enhance our operations, help us integrate renewable energy, and play an important role in achieving our clean energy vision. At the same time, storage is not a silver bullet that would solve all electricity system challenges. While we see storage as a growing part of our energy system, it must be part of a diverse clean energy portfolio. Storage has inherent limitations that policy makers and utilities must keep in mind as we invest in the energy system of the future.

A. Seasonal Renewable Variation

Xcel Energy has been a long-time leader in renewable energy, and has done nation-leading work to integrate growing levels of renewables across our system. Wind and solar have been a key part of our strategy for more than a decade, and we plan to continue to add renewable energy as long as we can do so cost effectively and reliably.

As discussed above, storage has growing value to help integrate renewable energy on the electric system. Seasonal variation in renewable generation is the primary reason that the cost of renewable energy grows so substantially as renewable penetration increases. The Clean Air Task Force (CATF) chart below shows that, during the periods when renewable output is very high, the California energy system would generate substantial additional renewable energy. This additional renewable energy would have to charge a massive amount of storage capacity to ensure that load is served when renewable output is relatively low.

**Figure 1: Clean Air Task Force –
Smoothed Daily Load and Renewable Energy Generation, Mixed Renewable Scenario**



In fact, CATF estimates that 9.6 million MW-hours of energy storage would be required to achieve 80 percent renewables in California—compared to the roughly 150,000 MW-hours of storage in California now. To reach 100 percent renewables, CATF has concluded that California would need 36 million MW-hours of storage. The cost of storage to achieve 100 percent renewable electricity in California would be astronomical – an estimated $3.6 trillion in capital costs to store all the surplus renewable generation, even assuming a 60 percent drop from today's storage costs.

We believe similar challenges would exist on our system. Based on E3's analysis of our carbon reduction scenarios for our Upper Midwest System, excluding new gas resources more than doubles the costs of reducing CO_2 emissions 85% by 2030 and 95% by 2045 compared to reaching the same goal with only renewable energy and storage additions.[5]

We remain committed to providing our customers with a carbon-free electric system, and we will add renewable energy to that system as long as it makes sense. We expect that storage will play an important role in a future clean energy system. However, given the huge challenge of seasonal variation in renewable generation, it is not realistic to expect that storage will make a 100 percent renewable energy system possible. Storage alone cannot provide our customers with the reliable and affordable

[5] Energy and Environmental Economics analysis of Low Carbon Scenarios on Xcel Energy's Upper Midwest System (E3 System Study), Appendix P2.

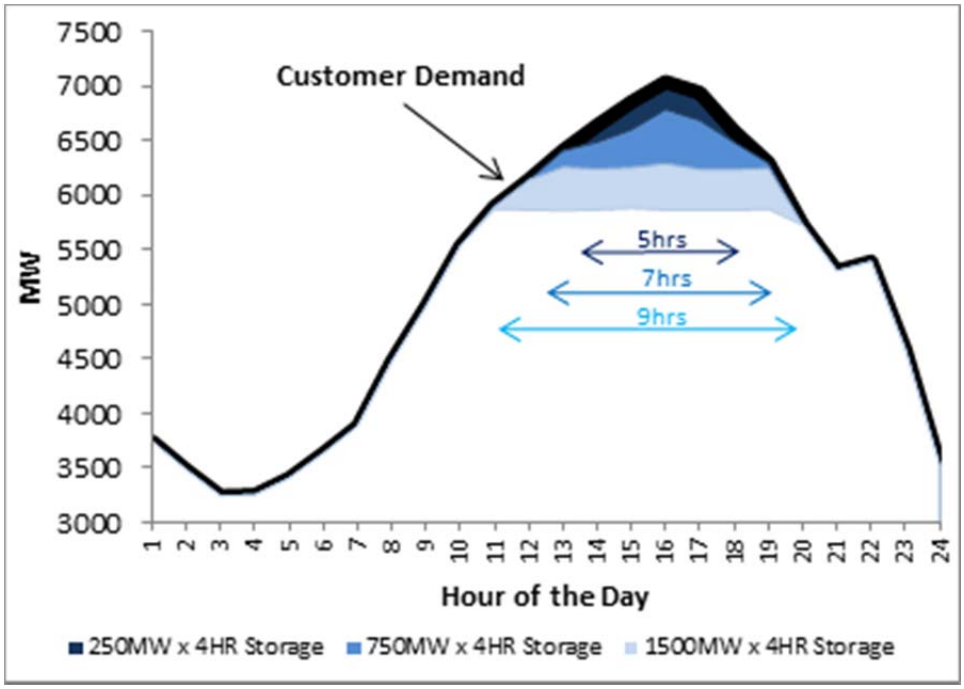
energy that they need. A broader suite of new dispatchable zero carbon technologies will be key to achieving our long-term carbon goals.

B. Declining Marginal Capacity Value

Storage can help meet peak energy demand by shifting some excess renewable energy to periods when it is needed, but this value declines dramatically as more storage is added to the system. As its name implies, a system peak is like the top of a mountain or a pyramid. It represents a short period of time during each day when energy usage is at its highest. Energy storage can shave off and lower the top of the peak, but it also widens it. As a result, larger, more expensive storage systems are required to further reduce the system energy needs.

The following chart illustrates this problem. The black line represents a single illustrative day of energy demand for one of our operating companies. Suppose that a 250 MW battery with four hours of storage capability is added to the system. It will shave off the top of the peak for a five hour period and shift the curve so that it takes advantage of parts of the day where excess renewables may be generated. The result is a lower, wider peak – more like a plateau. The next tranche of peak reductions requires substantially more storage to achieve the same effect – in this example, 750 MW of four hour batteries that are able to discharge over an approximately 7-hour period. The next tranche of demand reduction will require an even more substantial investment in storage i.e. a 1500 MW battery operating for almost 9 hours.

Figure 2: Battery Storage for Peak Demand Reduction



This chart illustrates that more batteries with longer duration are required at each step to reduce the peak. This problem is further compounded during periods of low renewable production, when excess generation may not be available to re-charge batteries to be available for the next peak.[6] At some point, it is not technically or economically feasible to continue to use storage to shift energy from off-peak to on-peak periods.

C. Stacking Storage Values

As referenced above, storage provides multiple values, each of which can enhance the operation and efficiency of the grid. Adding multiple values together – "stacking" – can make the storage resource more valuable as a whole. For example, a storage resource that provides voltage support and renewable integration will be more valuable than a storage resource that provides only one of these benefits. As the cost of storage continues to decline, stacking these benefits together increases the probability that a utility would choose to add a battery or other storage resource to its system.

[6] See E3 System Study, Figure 4-4, Appendix P2.

At the same time, in determining the value of a storage resource, its multiple potential benefits should not be added if one value precludes another. A battery may simultaneously provide voltage support and frequency regulation, but it cannot, for example, simultaneously integrate renewables and provide black start capability. In the latter case, the battery must be available to restart the system, and it may not be available to do so if it has been discharged to integrate renewables. Thus, the value of storage must be determined based on a utilities need for the potential value streams storage provides, and the ability and efficiency of storage to meet those needs.

V. ENERGY STORAGE ANALYSIS IN THE RESOURCE PLAN

We are considering storage opportunities in our resource planning processes in a number of our states. As mentioned above, our Colorado system already has 324 MW of pumped storage and we will be adding another 275 MW of storage embedded in solar by 2022. In this Resource Plan analysis we included a four hour generic battery storage resource in the modeling as an option to meet energy and capacity needs. The characteristics and cost assumptions for the storage resource can be found in the Strategist Assumptions in Appendix F2. In our modeling, the generic storage was allowed to compete with other resources to meet energy and capacity needs per the statutory requirement. If we have future needs, our model will select storage when it is a cost-effective resource. We continue to consider new tools and processes to analyze the appropriate location and size of storage solutions including the evaluation of potential values storage assets might provide to the system.

The Strategist model includes a spinning reserve requirement of 137 MW based on a 12 month rolling average of spinning reserves carried by the NSP System within MISO. Strategist does not account for other ancillary services and the associated value storage or any other resource may provide. Costs related to integrating renewables are included in Strategist by adding an integration cost to wind and solar.

Included as Appendix P2 is E3's Low Carbon Scenario analysis which used E3's RESOLVE model to evaluate deep decarbonization scenarios on our Upper Midwest System. The RESOLVE model utilizes a chronological hourly dispatch in contrast to the load duration curve methodology utilized by Strategist. In addition, RESOLVE includes the following operating reserve requirements which must be met by each resource portfolio:

1. Load following reserves requirements are set at 3% of load;
2. Frequency regulation reserve requirements are 27 MW; and
3. Spin reserve requirements are set at 1% of load.

The conclusions of E3's Low Carbon Scenario analysis generally support our preferred plan as a least cost way to achieve deep reductions in CO_2 emissions. Regarding storage, E3's analysis found the storage additions were not cost-effective on our system in the near-term, but were selected later in the planning period.

We will continue to evaluate storage in future resource plans, and will acquire new modeling tools that are better able to analyze high renewable scenarios. We expect storage to be part of our resource portfolio as costs continue to decline and we add more renewables to our system. Like other resources, much of the value of storage is in its ability to provide capacity and energy (arbitrage) and therefore it is primarily those needs will help drive storage additions in the future. Given our excess capacity position thru the mid-2020s, storage is unlikely to be cost-effective in the near term. However, the Company will continue to explore near term storage opportunities that could provide value to our system. In addition, storage resource will be considered to help meet firm, dispatchable capacity needs that have been identified in our Preferred Plan in the 2030s.

The Potential for Load Flexibility in Xcel Energy's Northern States Power Service Territory

This report was prepared for Xcel Energy, in accordance with The Brattle Group's engagement terms, and is intended to be read and used as a whole and not in parts. The report reflects the analyses and opinions of the authors and does not necessarily reflect those of The Brattle Group's clients or other consultants. There are no third party beneficiaries with respect to this report, and The Brattle Group does not accept any liability to any third party in respect of the contents of this report or any actions taken or decisions made as a consequence of the information set forth herein.

The authors would like to thank Jessie Peterson of Xcel Energy for valuable project leadership. They would also like to thank Brattle colleagues Mariko Geronimo Aydin, Colin McIntyre, and John Palfreyman for excellent research and modeling assistance.

About the Authors

Ryan Hledik is a Principal in The Brattle Group's New York office. He specializes in regulatory and planning matters related to the emergence of distributed energy technologies. Mr. Hledik received his M.S. in Management Science and Engineering from Stanford University, with a concentration in Energy Economics and Policy. He received his B.S. in Applied Science from the University of Pennsylvania, with minors in Economics and Mathematics.

Ahmad Faruqui is a Principal in The Brattle Group's San Francisco office. His areas of expertise include rate design, demand response, energy efficiency, distributed energy resources, advanced metering infrastructure, plug-in electric vehicles, energy storage, inter-fuel substitution, combined heat and power, microgrids, and demand forecasting. He holds B.A. and M.A. degrees from the University of Karachi in economics, an M.A. in agricultural economics and a Ph.D. in economics from The University of California, Davis.

Pearl Donohoo-Vallett is an Associate in The Brattle Group's Washington, D.C. office. She focuses on the increasing overlap of retail and wholesale regulatory issues with an emphasis on infrastructure investment and distributed energy resources. Dr. Donohoo-Vallett earned her Ph.D. in Technology, Management, and Policy and her S.M. in Technology and Policy from the Massachusetts Institute of Technology. She earned her B.S. in Mechanical Engineering from the Franklin W. Olin College of Engineering.

Tony Lee is a Senior Research Analyst in The Brattle Group's New York office. He supports clients on environmental policy analysis, wholesale market design, and economic analyses of generation, transmission and distributed energy resources. He holds Bachelor's Degrees in Economics and Engineering from Swarthmore College.

Executive Summary

Highlights:

- This study estimates the amount of cost-effective demand response available in Xcel Energy's Northern States Power (NSP) service territory, including an assessment of emerging "load flexibility" programs that can capture advanced sources of value such as geo-targeted distribution investment deferral and grid balancing services.
- Through 2023, NSP's cost-effective DR opportunities are constrained by limitations of its existing metering technology, access to low-cost peaking capacity, a limited need for distribution capacity deferral and grid balancing services, and relatively high costs of emerging DR technologies.
- In later years of the study horizon, and under conditions that are more favorable to the economics of DR, cost-effective DR potential increases significantly, exceeding the PUC's 400 MW DR procurement requirement.
- New, emerging load flexibility programs account for around 30% of the 2030 incremental DR potential estimates in this study.

Background

The purpose of this study is to estimate the potential capability of all cost-effective demand response (DR) that could be deployed in Xcel Energy's Northern States Power (NSP) service territory through 2030.[1] The study addresses the Minnesota PUC's requirement that NSP "acquire no less than 400 MW of additional demand response by 2023" and "provide a full and thorough cost-effectiveness study that takes into account the technical and economic achievability of 1,000 MW of additional demand response, or approximately 20% of Xcel's system peak in total by 2025."

The scope of this study extends significantly beyond those of prior studies. Specifically, we account for opportunities enabled by the rapid emergence of consumer-oriented energy technologies. Advanced metering infrastructure (AMI), smart appliances, electric vehicles, behavioral tools, and automated load control for large buildings are just a few of the technologies driving a resurgence of interest in the value that can be created through new DR programs. These technologies enable DR to evolve from providing conventional peak shaving services to providing around-the-clock

[1] Throughout this study, we simply refer to Xcel Energy as "NSP" when describing matters relevant to its NSP service territory.

"load flexibility" in which electricity consumption is managed in real-to address economic and system reliability conditions.

This study also takes a detailed approach to assessing the cost-effectiveness of each DR option. While emerging DR programs introduce the potential to capture new value streams, they are also dependent on technologies that in some cases have not yet experienced meaningful cost declines. Further, opportunities to create value through DR vary significantly from one system to the next. A detailed assessment of the costs and benefits of each available DR option is necessary to identify the DR portfolio that is the right "fit" for a given utility system.

The Brattle Group's Load*Flex* model is used to assess NSP's emerging DR opportunities. The Load*Flex* modeling framework builds upon the standard approach to quantifying DR potential that has been used in prior studies around the U.S. and internationally, but incorporates a number of differentiating features which allow for a more robust evaluation of load flexibility programs:

- **Economically optimized enrollment:** Assumed participation in DR programs is tailored to the incentive payment levels that are cost-effective for the DR program, thus providing a more complete estimate of total cost-effective potential than prior methodologies.
- **Utility-calibrated load impacts:** Load impacts are calibrated to the characteristics of NSP's customer base. This includes accounting for the market saturation of various end-use appliances, customer segmentation based on size, and NSP's estimates of the capability of its existing DR programs.
- **Sophisticated DR program dispatch:** DR program dispatch is optimized subject to detailed accounting for the operational constraints of the program, including tariff-related program limitations and an hourly representation of load control capability for each program.
- **Realistic accounting for "value stacking":** DR program operations are simulated to maximize total benefits across multiple value streams, while recognizing the operational constraints of the program and accounting for necessary tradeoffs when pursuing multiple value streams.
- **Industry-validated program costs:** DR program costs are based on a detailed review of NSP's current DR offerings, a review of experience and studies in other jurisdictions, and conversations with vendors.

Findings

Base Case

NSP currently has one of the largest DR portfolios in the country, with 850 MW of load curtailment capability (equivalent to roughly 10% of NSP's system peak). The portfolio primarily consists of an interruptible tariff program for medium and large C&I customers, and a residential air-conditioning direct load control (DLC) program. The DLC program is transitioning from utilizing a conventional compressor switch technology to instead leveraging newer smart thermostats.

There is an opportunity to tap into latent interest in the current NSP programs and grow participation in those existing programs through new marketing efforts and refinements to program design. According to our analysis, doing so could provide 293 MW of incremental cost-effective potential by 2023. The majority of this growth could come from increased enrollment in a redesigned interruptible tariff program for the medium and large C&I segments, and from the transition to a residential air-conditioning DLC program that more heavily utilizes smart thermostat technology.

NSP's DR portfolio could also be expanded to include new programs that are not currently offered by the company. Our analysis considered eight new programs, including time-of-use (TOU) rates, critical peak pricing (CPP), home and workplace EV charging load control, timer-based water heating load control and a more advanced "smart" water heating program, behavioral DR, ice-based thermal storage, and automated DR for lighting and HVAC of commercial and industrial customers. Some of these programs could provide ancillary services and geo-targeted distribution deferral benefits, in addition to the conventional DR value streams.

Based on current expectations about the future characteristics of the NSP market, smart water heating is the only new program that we find to be cost-effective in 2023 among the emerging options described above, providing an additional 13 MW of incremental cost-effective potential. Through 2023, NSP's cost-effective DR opportunities are constrained by limitations of its existing metering technology, access to low-cost peaking capacity, a limited need for distribution capacity deferral and frequency regulation, and relatively high costs of emerging DR technologies.

This expanded portfolio, which reflects all cost-effective DR options available to NSP across a broad range of potential use cases, would fall short of the PUC's 2023 procurement requirement. In 2023, the current portfolio plus the incremental cost-effective DR identified in this study would equate to 1,156 MW of total peak reduction capability, 154 MW short of the procurement requirement.[2]

In 2025, the potential in the expanded portfolio increases. This increase is driven primarily by the ability to begin offering time-varying rates once smart meters are fully deployed in 2024. However, it is likely that several years will be needed for smart metering-based programs to ramp up to full participation, so the incremental potential associated with these programs is still somewhat constrained in 2025. The current portfolio plus the incremental DR in the expanded portfolio equate to 1,243 MW of cost-effective DR potential in 2025.

By 2030, NSP's cost-effective DR potential will increase further. This increase is driven primarily by the maturation of smart metering-based DR programs. Other factors contributing to the increase in cost-effective potential include a continued transition to air-conditioning load control through smart thermostats, an expansion of the smart water heating program through ongoing

[2] NSP has interpreted the PUC's Order to require 400 MW of capacity-equivalent DR, which equates to 391 MW of generator-level load reduction when accounting for the reserve requirement, and 362 MW of meter-level load reduction when additionally accounting for line losses.

voluntary replacements of expiring conventional electric water heaters, and overall growth in NSP's customer base. By 2030, we estimate that NSP's current portfolio plus the incremental cost-effective DR would amount to 468 MW. New, emerging DR programs account for 33% of the incremental potential. Achieving this potential would require not only growth in existing programs, but the design and implementation of several new DR program as well.

High Sensitivity Case

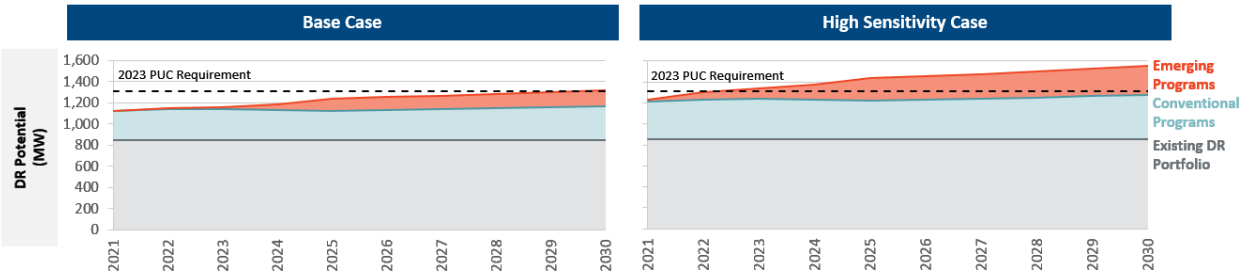
NSP's market may evolve to create more economically favorable conditions for DR than currently expected. For instance, growth in market adoption of intermittent renewable generation could contribute to energy price volatility and an increased need for high-value grid balancing services. Further, the costs of emerging DR technologies may decline significantly, or the cost of competing resources (e.g., peaking capacity) may be higher than expected. To understand how these alternative conditions would impact DR potential, we analyzed a sensitivity case. The High Sensitivity Case illustrates the potential for DR under an alternative set of market conditions that are more favorable to DR program economics. The case is not a forecast of what is likely to happen in the future in NSP's service territory, particularly in the near-term years of the study horizon.

Under the illustrative assumptions of the High Sensitivity Case there is significantly more cost-effective incremental potential. In 2023 there is a total of 484 MW of incremental cost effective potential, which would satisfy the PUC's procurement requirement. By 2030, the total portfolio of DR programs, including the existing programs, could reach 705 MW.

The mix of cost-effective programs in the High Sensitivity case is essentially the same as in the Base Case. However, larger program benefits justify higher incentive payments, which leads to higher participation and overall potential in these programs. Auto-DR for C&I customers also presents an opportunity to increase load flexibility in the High Sensitivity Case, though the potential in this program is subject to uncertainty in technology cost and customer adoption.

Under both the Base Case and the High Sensitivity Case assumptions, avoided generation capacity costs are the primary benefit of the DR portfolio. In the High Sensitivity Case, additional price volatility due a greater assumed mix of renewable generation in the regional supply portfolio leads to an increase in the share of total that is attributable to avoided energy costs. The total value of frequency regulation provided by DR also increases modestly relative to the Base Case, as a greater need for this service is assumed for renewable generation integration purposes. Figure ES-1 summarizes the DR potential estimates and benefits of the DR portfolio under Base Case and High Sensitivity Case assumptions.

Figure ES-1: NSP's DR Potential and Annual Portfolio Benefits



2030 Avoided Cost ($M/yr)

	Energy	Generation Capacity	System Average T&D Deferral	Geotargeted Distribution Deferral	Frequency Regulation	Total
Conventional Programs	$1.7	$15.5	$0.9	$0.0	$0.0	$18.1
Emerging Programs	$5.7	$7.4	$0.4	$0.0	$1.2	$14.7
Total	$7.4	$22.9	$1.3	$0.0	$1.2	$32.8

	Energy	Generation Capacity	System Average T&D Deferral	Geotargeted Distribution Deferral	Frequency Regulation	Total
Conventional Programs	$3.1	$26.8	$1.1	$0.0	$0.0	$31.0
Emerging Programs	$19.6	$19.5	$0.8	$0.7	$4.6	$45.2
Total	$22.7	$46.3	$1.9	$0.7	$4.6	$76.2

Notes: Benefits shown in 2023 dollars. Estimates include benefits from NSP's existing 850 MW portfolio.

An expanded portfolio of DR programs will have operational flexibility beyond the capabilities of conventional existing programs. For instance, load flexibility programs could be dispatched to reduce the system peak, but also to address local peaks on the distribution system which may occur during later hours of the day. Off-peak load building through electric water heating could help to mitigate wind curtailments and take advantage of negative energy prices. The provision of frequency regulation from electric water heaters could further contribute to renewables integration value.

Specific recommendations for acting on the findings of this study including the following:

- Aggressively pursue the transition to smart thermostats as well as recruitment of medium C&I customers into the Interruptible program.
- Pilot and deploy a smart water heating program. As a complementary activity, evaluate the impacts of switching from gas to electric heating, accounting for the grid reliability benefits associated with this flexible source of load.
- Prior to the smart metering rollout, build the foundation for a robust offering of time-varying rates, including identifying rate options that could be offered on an opt-out basis.
- Develop measurement & verification (M&V) 2.0 protocols to ensure that program impacts are dependable and can be integrated meaningfully into resource planning efforts.
- Design programs with peak period flexibility, to be able to respond to changes such as a shifts in the net peak due to solar PV adoption, or a shift in the planning emphasis from a focus on the MISO peak to a focus on more local peaks, for instance.

I. Introduction

Purpose

The purpose of this study is to estimate the potential capability of all cost-effective demand response (DR) that could be deployed in Xcel Energy's Northern States Power (NSP) service territory.[3] Xcel Energy commissioned this study to satisfy the requirements of the Minnesota Public Utilities Commission (PUC) Order in Docket No. E-002/RP-15-21. That Order, established in January 2017, required NSP to "acquire no less than 400 MW of additional demand response by 2023" and to "provide a full and thorough cost-effectiveness study that takes into account the technical and economic achievability of 1,000 MW of additional demand response, or approximately 20% of Xcel's system peak in total by 2025."

Background

The Brattle Group conducted an assessment of NSP's DR potential in 2014.[4] That study specifically addressed opportunities to reduce NSP's system peak demand. As such, the assessment had a primary focus on "conventional" DR programs that are utilized infrequently to mitigate system reliability concerns. The study also included price-based DR options that would be enabled by the eventual deployment of smart meters.

The scope of this 2018 study extends significantly beyond that of the 2014 study. Specifically, we account for opportunities enabled by the rapid emergence of consumer-oriented energy technologies. Advanced metering infrastructure (AMI), smart appliances, electric vehicles, behavioral tools, and automated load control for large buildings are just a few of the technologies driving a resurgence of interest in the value that can be created through new DR programs. These technologies enable DR to evolve from providing conventional peak shaving services to providing around-the-clock "load flexibility" in which electricity consumption is managed in real-to address economic and system reliability conditions. The Brattle Group's Load*Flex* model is used to assess these emerging opportunities.

---

[3] Throughout this study, we simply refer to Xcel Energy as "NSP" when describing matters relevant to its NSP service territory.

[4] Ryan Hledik, Ahmad Faruqui, and David Lineweber, "Demand Response Market Potential in Xcel Energy's Northern States Power Service Territory," prepared for Xcel Energy, April 2014.

This 2018 study also extends beyond the scope of the 2014 study by evaluating the cost-effectiveness of each DR option.[5] While emerging DR programs introduce the potential to capture new value streams, they are also dependent on technologies that in some cases have not yet experienced meaningful cost declines. Further, opportunities to create value through DR vary significantly from one system to the next. A utility with significant market penetration of solar PV may find the most value in advanced load shifting capabilities that address evening generation ramping issues on a daily basis, whereas a system with a near-term need for peaking capacity may find more value in the types of conventional DR programs that reduce the system peak during only a limited number of hours per year. A detailed assessment of the costs and benefits of each available DR option is necessary to identify the DR portfolio that is the right "fit" for a given utility system.

This report summarizes the key findings of The Brattle Group's assessment of NSP's DR market potential. Additional detail on methodology and results is provided in the appendices.

NSP's Existing DR Portfolio

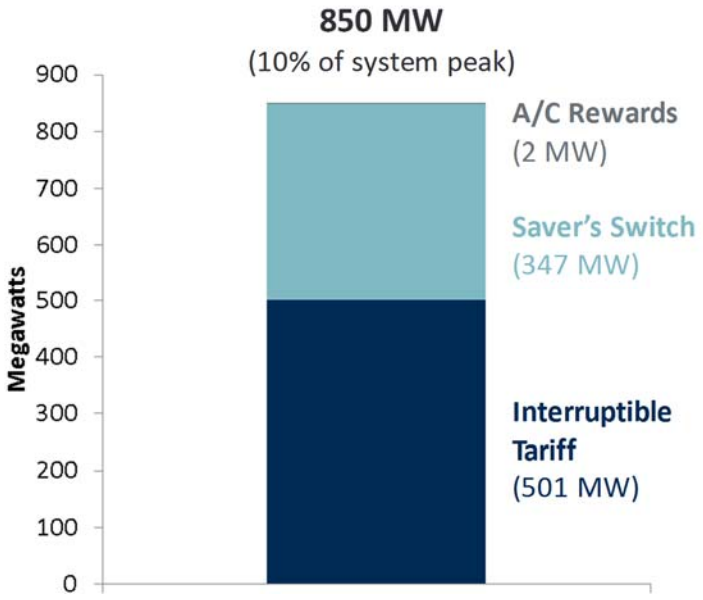
The capability of NSP's existing DR portfolio is substantial. It is the eighth largest portfolio among all US investor-owned utilities when DR capability is expressed as a percentage of peak demand. The portfolio is the largest in MISO in terms of total megawatt capability, and second when expressed as a percentage of peak demand.

As of 2017, Xcel Energy had 850 MW of DR capability across its NSP service territory, accounting for roughly 10 percent of system peak demand. This capability comes primarily from two programs. The largest is an "interruptible tariff" program, which provides commercial and industrial (C&I) customers with energy bill savings in return for a commitment to curtail electricity demand to pre-established levels when called upon by the utility. Roughly 11 percent of the peak-coincident demand of medium and large C&I customers is enrolled in this program.

The second program is NSP's Saver's Switch program. Saver's Switch is a conventional residential load control program, in which the compressor of a central air-conditioning unit or the heating element of an electric resistance water heater is temporarily cycled off to reduce electricity demand during DR events. Saver's Switch is one of the largest such programs in the country. Roughly 52 percent of all eligible residential customers (i.e., those with central air-conditioning) are enrolled in the program, accounting for around 29% of all of NSP's residential customers. Saver's Switch is gradually being transitioned to a program based on newer smart thermostat technology, called "A/C Rewards." A/C Rewards contributes an additional 2 MW to NSP's existing DR capability, though this is expected to grow significantly in coming years. A summary of NSP's DR portfolio is provided in Figure 1.

[5] The 2014 study developed a "supply curve" of DR options available to NSP as inputs to its integrated resource plan (IRP), but did not explicitly evaluate the extent to which those options would be less costly than serving electricity demand through the development of new generation resources.

Figure 1: NSP 2017 DR Capability



Sources: NSP 2017 DR program data and 2017 NSP system peak demand (8,546 MW)

Important Considerations

The focus of this study is on quantifying the amount of cost-effective DR capability that can be achieved above and beyond NSP's current 850 MW DR portfolio. We estimate the incremental DR potential that can be achieved through an expansion of existing program offerings, the introduction of new programs, and consideration of a broad range of potential system benefits that are available through DR. Specifically, this study is structured to quantify all DR potential that satisfies the following three conditions:

1. **Incremental:** All quantified DR potential is incremental to NSP's existing 850 MW DR portfolio.[6]

2. **Cost-effective:** The present value of avoided resource costs (i.e., benefits) must outweigh program costs, equipment costs, and incentives.

3. **Achievable:** Program enrollment rates are based on primary market research in NSP's service territory and supplemented with information about utility experience in other jurisdictions.

[6] For the purposes of this analysis, all incremental potential estimates assume NSP's portfolio of existing programs continues to be offered as currently designed in future years, and that the 850 MW impact persists throughout the forecast horizon. Existing DR participants are excluded from the estimates of incremental potential.

The findings of this study should be interpreted as a quantitative screen of the DR opportunities available to NSP. Further development of individual programs, and testing of the programs through pilots, will provide additional insight regarding the potential benefits and costs that such programs may offer to NSP and its customers when deployed on a full scale basis.

II. Methodology

This study analyzes three ways to increase the capability of NSP's existing DR portfolio. First, we assess the potential to increase enrollment in existing programs. Increased enrollment could be achieved through targeted program marketing efforts, for example. Second, the menu of DR programs offered to customers could be expanded to include new, non-conventional options. These non-conventional options include emerging "load flexibility" programs which go beyond peak shaving to provide around-the-clock decreases and increases in system load. Third, consistent with the introduction of more flexible DR programs, we consider a broadened list of potential benefits in the cost-effectiveness screening process, such as ancillary services and geographically-targeted deferral of distribution capacity upgrades.

Conventional DR Programs

Our analysis considers conventional DR programs that have been offered by utilities for many years, including in some cases by NSP.

- **Direct load control (DLC):** Participant's central air-conditioner is remotely cycled using a switch on the compressor. The modeled program is based on NSP's Savers Switch program.

- **Smart thermostats:** An alternative to conventional DLC, smart thermostats allow the temperature setpoint to be remotely controlled to reduce A/C usage during peak times. The modeled program is based on NSP's A/C Rewards program, which provides customers with options to use their own thermostat, self-install a thermostat purchased from NSP's online store, or use a NSP-installed thermostat. Smart thermostat programs are based on newer technology than the other "conventional" DR programs in this list, but included here as the program is already offered by NSP.

- **Interruptible rates:** Participants agree to reduce demand to a pre-specified level and receive an incentive payment in the form of a discounted rate.

- **Demand bidding:** Participants submit hourly curtailment schedules on a daily basis and, if the bids are accepted, must curtail the bid load amount to receive the bid incentive payment or may be subject to a non-compliance penalty. While a conventional option, demand bidding is not currently offered by NSP.

Non-conventional DR Programs

Pricing programs are one type of non-conventional DR option. We consider two specific time-varying rate options which generally span the range of impacts that can be achieved through pricing programs: A static time-of-use rate and a dynamic critical peak pricing rate.

- **Time-of-use (TOU) rate:** Currently being piloted by NSP for residential customers and offered on a full-scale basis to C&I customers. Static price signal with higher price during peak hours (assumed 5-hour period aligned with system peak) on non-holiday weekdays. Modeled as being offered on an opt-in and an opt-out (default) basis. The study also includes an optional TOU rate for EV charging.

- **Critical peak pricing (CPP) rate:** Provides customers with a discounted rate during most hours of the year, and a much higher rate (typically between 50 cents/kWh and $1/kWh) during peak hours on 10 to 15 days per year. CPP rates are modeled as being offered on both an opt-in and an opt-out (default) basis.

The second category of non-conventional DR programs relies on a variety of advanced behavioral and technological tools for managing customer electricity demand.

- **Behavioral DR:** Customers are informed of the need for load reductions during peak times without being provided an accompanying financial incentive. Customers are typically informed of the need for load reductions on a day-ahead basis and events are called somewhat sparingly throughout the year. Behavioral DR programs have been piloted by several utilities, including Consumers Energy, Green Mountain Power, the City of Glendale, Baltimore Gas & Electric, and four Minnesota cooperatives.

- **EV managed charging:** Using communications-enabled smart chargers allows the utility to shift charging load of individual EVs plugged-in from on-peak to off-peak hours. Customers who do not opt-out of an event receive a financial incentive. The managed EV charging program was modeled on three recent pilots: PG&E (with BMW), United Energy (Australia), and SMUD. Allows curtailment of charging load for up to three hours per day, fifteen days per year. Impacts were modeled for both home charging and workplace charging programs.

- **Timed water heating:** The heating element of electric resistance water heaters can be set to heat water during off-peak hours of the day. The thermal storage capabilities of the water tank provide sufficient hot water during peak hours without needing to activate the heating element.

- **Smart water heating:** Offers improved flexibility and functionality in the control of the heating element in the water heater. The thermostat can be modulated across a range of temperatures. Multiple load control strategies are possible, such as peak shaving, energy

price arbitrage through day/night thermal storage, or the provision of ancillary services such as frequency regulation. Modeled for electric resistance water heaters, as these represent the vast majority of electric water heaters and are currently the most attractive candidates for a range of advanced load control strategies.

- **Ice-based thermal storage:** Commercial customers shift peak cooling demand to off-peak hours using ice-based storage systems. The thermal storage unit acts as a battery for the customer's A/C unit, charging at night (freezing water) and discharging (allowing ice to thaw to provide cooling) during the day.

- **C&I Auto-DR:** Auto-DR technology automates the control of various C&I end-uses. Features of the technology allow for deep curtailment during peak events, moderate load shifting on a daily basis, and load increases and decreases to provide ancillary services. Modeled end-uses include HVAC and lighting (both luminaire and zonal lighting options).

DR Benefits

This study accounts for value streams that are commonly included in assessments of DR potential:

- **Avoided generation capacity costs:** The need for new peaking capacity can be reduced by lowering system peak demand. Important considerations when estimating the equivalence of DR and a peaking generation unit are discussed later in this section of the report.

- **Reduced peak energy costs:** Reducing load during high priced hours leads to a reduction in energy costs. Our analysis estimates net avoided energy costs, accounting for costs associated with the increase in energy consumption during lower cost hours due to "load building." The energy benefit accounts for avoided average line losses. Our analysis likely includes a conservative estimate of this value, as peak line losses are greater than off-peak line losses. Our analysis does not include the effect of any potential change in energy market prices that may result from changes in load patterns (sometimes referred to as the "demand response induced price effect," or DRIPE). It is simply a calculation of reduced resource costs.

- **System-wide deferral of transmission and distribution (T&D) capacity costs.** System-wide reductions in peak demand can, on average, contribute to the reduced need for peak-driven upgrades in T&D capacity. We account for this potential value using methods that were established in a recent Minnesota PUC proceeding.[7]

This study also accounts for value streams that can be captured through more advanced DR programs:

[7] Minnesota PUC Docket No. E999/CIP-16-541.

- **Geo-targeted distribution capacity investment deferral:** DR participants may be recruited in locations on the distribution system where load reductions would defer the need for capacity upgrades. NSP's 5-year distribution plan was used to identify candidate deferral projects, and qualifying DR programs were evaluated based on their ability to contribute to the deferral.[8]

- **Ancillary services:** The load of some end-uses can be increased or decreased in real time to mitigate system imbalances. The ability of qualifying DR programs to provide frequency regulation was modeled, as this is the highest-value ancillary service (albeit with limited system need).

- **Load building / valley filling:** Load can be shifted to off-peak hours to reduce wind curtailments or take advantage of low or negatively priced hours. DR was dispatched against hourly energy price series to capture the economic incentive that energy prices provide for this service.

Figure 2 summarizes the ways in which this assessment of DR potential extends the scope of prior studies in Minnesota and other jurisdictions. In the figure, "X" indicates the value streams that each DR program is assumed to provide.

Figure 2: Options for Expanding the Existing DR Portfolio

1 Increase enrollment in the conventional portfolio

2 Extend DR value streams

3 Include non-traditional DR options

	Generation capacity avoidance	Reduced peak energy costs	System peak related T&D deferral	Targeted distribution capacity deferral	Valley filling/ Load building	Ancillary services
Direct load control (DLC)	X	X	X			
Interruptible tariff	X	X	X			
Demand bidding	X	X	X		X	
Smart thermostat	X	X	X			
Time-of-use (TOU) rates	X	X	X			
Dynamic pricing	X	X	X			
Behavioral DR	X	X	X			
EV managed charging	X	X	X	X	X	
Smart water heating	X	X	X		X	X
Timed water heating	X	X	X		X	
Ice-based thermal storage	X	X	X	X	X	
C&I Auto-DR	X	X	X	X	X	X

Notes: "X" indicates the value streams that each DR option is assumed to be able to provide.

[8] The distribution plan was in-development at the time of our analysis. Distribution data was provided to Brattle in March 2018.

Defining DR Potential

We use the Utility Cost Test (UCT), also known as the Program Administrator Cost Test (PACT), to determine the cost-effectiveness of the incremental DR portfolio. The UCT determines whether a given DR program will increase or decrease the utility's revenue requirement. This is the same perspective that utilities take when deciding whether or not to invest in a supply-side resource (e.g., a combustion turbine) through the IRP process.[9] Since the purpose of this DR potential study is to determine the amount of DR that should be included in the IRP, the UCT was determined to be the appropriate perspective. Major categories of benefits and costs included in the UCT are summarized Table 1.

Table 1: Categories of Benefits and Costs included in the Utility Cost Test

Benefits	Costs
Avoided generation capacity	Incentive payments
Avoided peak energy costs	Utility equipment & installation
Avoided transmission capacity	Administration/overhead
Avoided distribution capacity	Marketing/promotion
Ancillary services	

Throughout this study, we quantify DR potential in two different ways:

Technical Potential: Represents achievable potential without consideration for cost-effectiveness. In other words, this is a measure of DR capability that could be achieved from anticipated enrollment associated with a moderate participation incentive payment, regardless of whether or not the incentive payment and other program costs exceed the program benefits. As it is used here, the term "technical potential" differs from its use in energy efficiency studies. Technical potential in energy efficiency studies assumes 100% participation, whereas we assume an achievable level of participation in this assessment of DR potential.

Cost-effective Potential: Represents the portion of technical potential that can be obtained at cost-effective incentive payment levels. For each program, the assumed participation incentive payment level is set such that the benefit-cost ratio is equal to 1.0. Participation rates are estimated to align with this incentive payment level. When non-incentive costs (e.g., equipment and installation costs) are found to outweigh the benefits alone, the benefit-cost ratio is less than 1.0 and there is no opportunity to offer a cost-effective participation incentive payment. In that case, the program is considered to have no cost-effective potential.

[9] According to the National Action Plan for Energy Efficiency: "The UCT is the appropriate cost test from a utility resource planning perspective, which typically aims to minimize a utility's lifecycle revenue requirements."

The Load*Flex* Model

The Brattle Group's Load*Flex* model was used to estimate DR potential in this study. The Load*Flex* modeling framework builds upon the standard approach to quantifying DR potential that has been used in prior studies around the U.S. and internationally, but incorporates a number of differentiating features which allow for a more robust evaluation of DR programs:

- **Economically optimized enrollment:** Assumed participation in DR programs is tailored to the incentive payment levels that are cost-effective for the DR program. If only a modest incentive payment can be justified in order to maintain a benefit-cost ratio of 1.0, then the participation rate is calibrated to be lower than if a more lucrative incentive payment were offered. Prior approaches to quantifying DR potential ignore this relationship between incentive payment level and participation, which tends to under-state the potential (and, in some cases, incorrectly concludes that a DR program would not pass the cost-effectiveness screen).

- **Utility-calibrated load impacts:** Load impacts are calibrated to the characteristics of NSP's customer base. In the residential sector, this includes accounting for the market saturation of various end-use appliances (e.g., central air-conditioning, electric water heating). In the commercial and industrial (C&I) sector, this includes accounting for customer segmentation based on size (i.e., the customer's maximum demand) and industry (e.g., hospital, university). Load curtailment capability is further calibrated to NSP's experience with DR programs where available (e.g., impacts from existing DLC programs or dynamic pricing pilots).

- **Sophisticated DR program dispatch:** DR program dispatch is optimized subject to detailed accounting for the operational constraints of the program. In addition to tariff-related program limitations (e.g., how often the program can be called, hours of the day when it can be called), Load*Flex* includes an hourly profile of load interruption capability for each program. For instance, for an EV home charging load control program, the model accounts for home charging patterns, which would provide greater average load reduction opportunities during evening hours (when EV owners have returned home from work) than in the middle of the day.

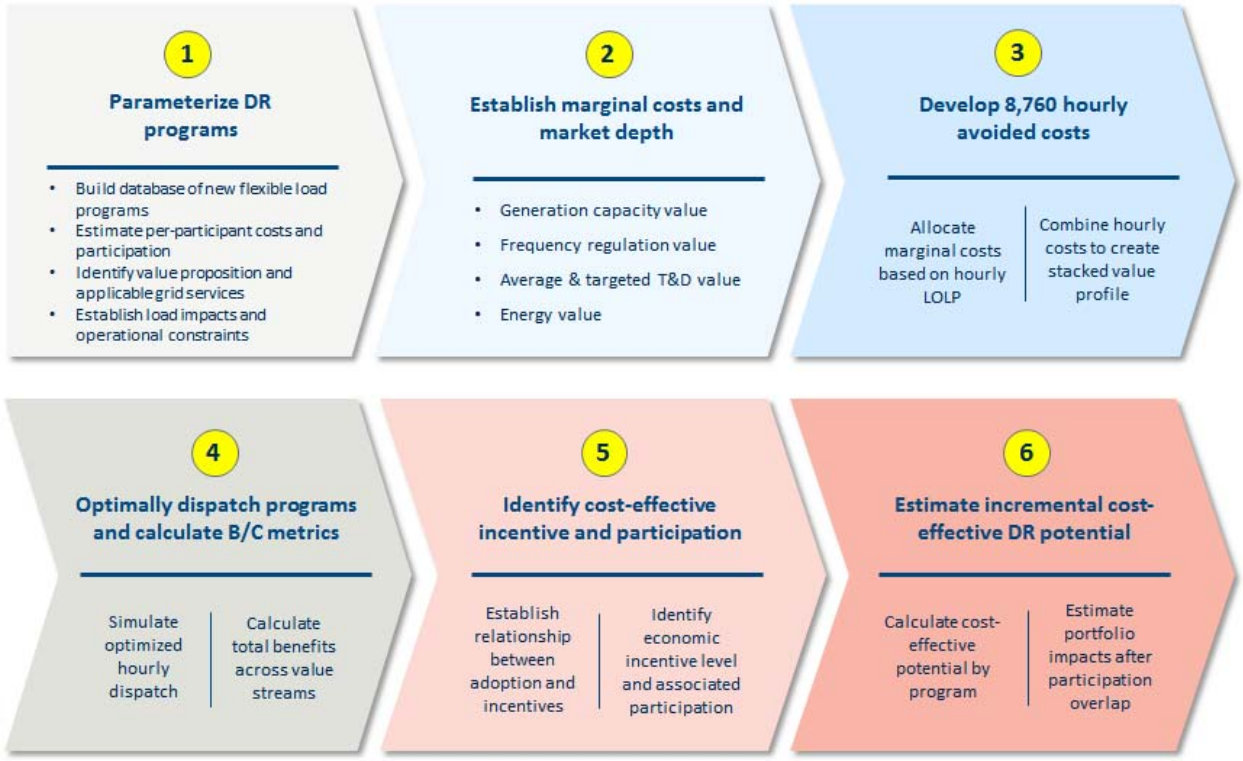
- **Realistic accounting for "value stacking":** DR programs have the potential to simultaneously provide multiple benefits. For instance, a DR program that is dispatched to reduce the system peak and therefore avoid generation capacity costs could also be dispatched to address local transmission or distribution system constraints. However, tradeoffs must be made in pursuing these value streams – curtailing load during certain hours of the day may prohibit that same load from being curtailed again later in the day for a different purpose. Load*Flex* accounts for these tradeoffs in its DR dispatch algorithm. DR program operations are simulated to maximize total benefits across multiple value streams, while recognizing the operational constraints of the program. Prior studies of load flexibility value have often

assigned multiple benefits to DR programs without accounting for these tradeoffs, thus double-counting benefits.

- **Industry-validated program costs:** DR program costs are based on a detailed review of NSP's current DR offerings. For new programs, costs are based on a review of experience and studies in other jurisdictions and conversations with vendors. Program costs are differentiated by type (e.g., equipment/installation, administrative) and structure (e.g., one-time investment, ongoing annual fee, per-kilowatt fee) to facilitate integration into utility resource planning models.

The Load*Flex* modeling framework is organized around six steps, as summarized in Figure 3. Appendix A provides detail on the methodology behind each of these steps.

Figure 3: The Load*Flex* Modeling Framework



Modeling Scenarios

The value that DR will provide depends on the underlying conditions of the utility system in which it is deployed. Generation capacity costs, the anticipated need for new transmission and distribution (T&D) assets, and energy price volatility are a few of the factors that will determine DR value and potential. To account for uncertainty in NSP's future system conditions, we considered two modeling scenarios: A "Base Case" and a "High Sensitivity Case."

The **Base Case** most closely aligns with NSP's expectations for future conditions on its system, as defined in its IRP. The Base Case represents a continuation of recent market trends, combined with information about known or planned developments during the planning horizon.

The **High Sensitivity Case** was developed to illustrate how the value of DR can change under alternative future market conditions. The High Sensitivity Case is defined by assumptions about the future state of the NSP system and MISO market that are more favorable to DR program economics. The High Sensitivity Case is not intended to be the most likely future state of the NSP system. Relative to the Base Case, the High Sensitivity Case consists of a higher assumed generation capacity cost, more volatile energy prices due to greater market penetration of renewable generation, a significant reduction in emerging DR technology costs, and an increase in the need for frequency regulation.

Defining features of the two cases are summarized in Table 2. Appendix A includes more detail on assumptions and data sources behind the two cases.

Table 2: Defining Features of Base Case and High Sensitivity Case

	Base Case	High Sensitivity Case
Generation capacity (Net CONE)	$64/kW-yr (2018 NSP IRP)	$93/kW-yr (2018 EIA Annual Energy Outlook)
Hourly energy price	Based on MISO MTEP "Continued Fleet Change" case (15% wind+solar by 2032)	Based on MISO MTEP "Accelerated Fleet Change" case (30% wind+solar by 2032)
Frequency regulation	Price varies, 25 MW average need by 2030	Price same as Base Case, 50 MW average need by 2030
System average T&D deferral	Transmission: $3.6/kW-yr, Distribution: $9.5/kW-yr (2017 NSP Avoided T&D Study)	Same as Base Case
Geo-targeted T&D deferral	Value varies by distribution project, 90 MW eligible for deferral by 2030	Same as Base Case
DR technology cost	10% reduction from current levels by 2030 (in real terms)	30% reduction from current levels by 2030 (in real terms)

Notes: Unless otherwise specified, values shown are for year 2030 and in nominal dollars.

Modeling results are summarized for the years 2023 and 2030. 2023 is the year by which NSP must procure additional DR capability according to the Minnesota PUC's Order in Docket No. E-002/RP-15-21. The 2030 snapshot captures the potential for significant future changes in system conditions and their implications for DR value, and is consistent with the longer-term perspective of NSP's IRP study horizon. A summary of annual results, including intermediate years, is provided in Appendix D.

Data

To develop participation, cost, and load impact assumptions for this study, we relied on a broad range of resources. Where applicable, we relied directly upon information from NSP's experience with DR programs in its service territory. We also utilized the results of primary market research that was conducted directly with customers in NSP's service territory in order to better understand their preferences for various DR program options. Where NSP-specific information was unavailable, we reviewed national data on DR programs, DR potential studies from other jurisdictions, and DR program impact evaluations. A complete list of resources is provided in the References section and described further in Appendix A.

In an assessment of emerging DR opportunities, it is important to recognize that data availability varies significantly by DR program type. Conventional DR programs, such as air-conditioning load control, have decades of experience as full-scale deployments around the US and internationally. By contrast, emerging DR programs like EV charging load control have only recently begun to be explored, largely through pilot projects. Figure 4 summarizes data availability for each of the DR program types analyzed in this study.

◑ Signficant program experience in other jurisdictions

◔ Some pilot or demonstration project experience in other jurisdictions

○ Speculative, estimated from theoretical studies and calibrated to NSP conditions

"Advanced impacts" refers to load flexibilty capability beyond conventional peak period reductions (e.g., frequency regulation)

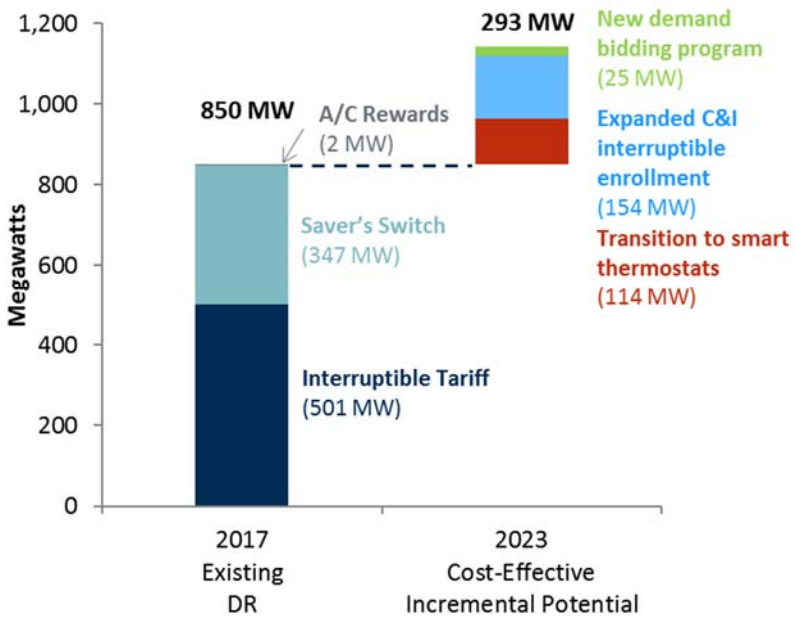
III. Conventional DR Potential in 2023

As an initial step in the assessment of NSP's cost-effective DR potential, we analyzed the potential if NSP were to deploy a portfolio of conventional DR programs. As defined for this study, conventional programs include interruptible tariffs, air-conditioning DLC, smart thermostats, and demand bidding. These program types are currently offered by NSP, with the exception of demand bidding. Therefore, the assessment of conventional programs is largely an assessment of the potential to grow the current DR portfolio through options such as new marketing initiatives or targeted marketing toward specific customer segments. We initially focus on the year 2023, as that is the year by which the Minnesota PUC has required NSP to procure additional DR capability.[10]

Figure 5 summarizes the cost-effective potential in a conventional DR portfolio in 2023. There is 293 MW of cost-effective incremental potential. Drivers of this potential include the expanded enrollment in NSP's interruptible tariff program, greater per-participant impacts that will be achieved as NSP continues to transition from a switch-based air-conditioning DLC program to a smart thermostat-based program, overall growth in NSP's customer base between 2017 and 2023, and a modest amount of potential in a new demand bidding program.

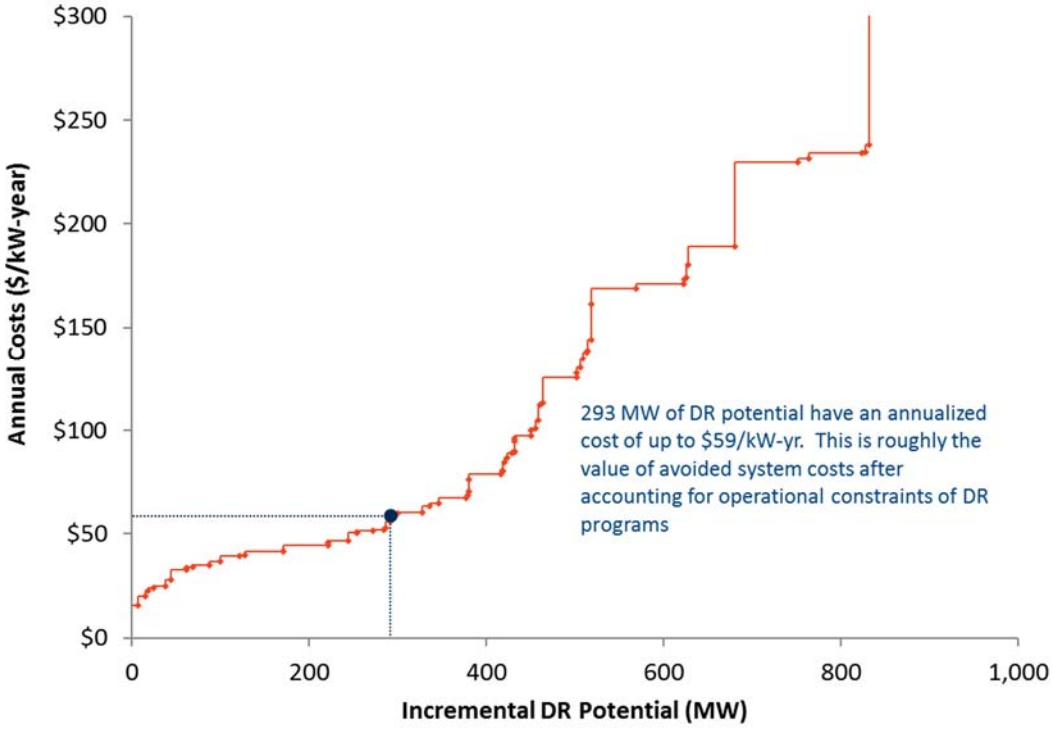
[10] NSP has interpreted the PUC's Order to require 400 MW of capacity-equivalent DR, which equates to 391 MW of generator-level load reduction when accounting for the reserve requirement, and 362 MW of meter-level load reduction when also accounting for line losses.

Figure 5: Total DR Potential in 2023 (Conventional Portfolio)



The incremental potential in conventional DR programs can be expressed as a "supply curve." Figure 6 illustrates the costs associated with achieving increasing levels of DR capability. The upward slope of the curve illustrates how DR capability (i.e., enrollment) increases as incentive payments increase. The curve also captures the different costs and potential associated with each conventional DR program and applicable customer segment. Cost-effective DR capability is identified with the blue dotted line. There is roughly 293 MW of incremental DR potential available at a cost of less than $59/kW-year. That cost equates to the value of avoided system costs after accounting for the operational constraints of DR programs.

Figure 6: NSP's Incremental DR Supply Curve in 2023 (Conventional Portfolio)



Note: Supply curve shows conventional DR potential without accounting for cost-effectiveness. Potential estimates if the DR options were offered simultaneously as part of a portfolio at each price point (i.e. accounts for overlap). Program costs presented in nominal terms.

As discussed previously in this report, the Minnesota PUC has established a DR procurement requirement of 400 MW by 2023. It is important to clarify whether this 400 MW is a capacity-equivalent value, a generator-level value, or a meter-level value. Specifically, 1 MW of load reduction at the meter (or customer premise) avoids more than 1 MW at the generator level due to line losses between the generator and the customer. Further, 1 MW of load reduction at the generator level provides more than 1 MW of full capacity-equivalent value, as the load reduction would also avoid the additional capacity associated with NSP's obligation to meet the planning reserve requirement. Based on NSP's calculations, which account for line losses and the reserve requirement, 1 MW of load reduction at the meter level equates to 1.08 MW of load reduction at the generator level and 1.11 MW of capacity-equivalent value.

NSP has interpreted the PUC's Order to require 400 MW of capacity-equivalent DR. This equates to 391 MW of generator-level load reduction when accounting for the reserve requirement, and 362 MW of meter-level load reduction when also accounting for line losses. These values are summarized in Table 3. Throughout this report, DR values are reported at the generator level. Thus, for consistency, we refer to the procurement requirement as a 391 MW generator-level value unless otherwise specified.

Table 3: NSP's 2023 DR Procurement Requirement

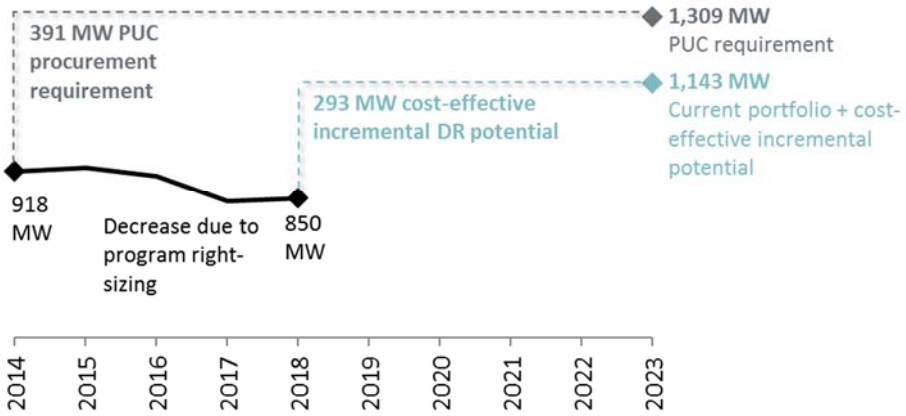
	Requirement (MW)	Notes
Meter level	361.7	Premise-level
Generator level	390.7	Grossed up for 8% line losses
Capacity equivalent	400.0	Grossed up for line losses and reserve requirement

Source: Calculations provided by NSP.

Our interpretation of the PUC's Order is that the required DR procurement is incremental to NSP's DR capability as it existed in 2014.[11] NSP had 918 MW of DR capability in 2014, leading to a total DR capability requirement of 1,309 MW in 2023. NSP's DR capability decreased between 2014 and 2017 largely due to an effort to ensure that enrolled load would be available for curtailment when called upon, thus leading to an incremental DR requirement that is larger than 391 MW (at the generator level).[12]

Combined with current capability of 850 MW, the incremental cost-effective DR potential in 2023 would result in a total portfolio of 1,143 MW. This estimate of cost-effective potential is 166 MW short of the PUC's DR procurement requirement. Figure 7 illustrates the gap between NSP's conventional DR potential and the DR procurement requirement.

Figure 7: NSP DR Capability (Conventional Portfolio)



Note: Chart is scaled such that vertical axis does not start at zero. 391 MW procurement requirement is expressed at the generator level and is equivalent to 400 MW of DR capacity.

[11] 2014 is the year of NSP's prior DR potential study, which was used to inform the Minnesota PUC's establishment of the DR procurement requirement.

[12] For instance, some customers did not realize that they were participating in the program and dropped out when notified, or otherwise elected to reduce their enrolled load level.

IV. Expanded DR Potential in 2023

Given the shortfall of the conventional DR portfolio relative to the 2023 procurement target, it is relevant to consider if an expanded portfolio of DR options could mitigate the shortfall. We analyzed eight additional emerging DR programs that could be offered to up to four different customer segments (if applicable). As described in Section II, these emerging DR options include both price based programs (e.g., TOU and CPP rate designs) and technology-based programs (e.g., Auto-DR and smart water heating).

Base Case

Among the individual measures with the most *technical potential* in 2023 are HVAC Auto-DR for Medium C&I customers and thermal storage for commercial customers. Each of these programs has technical potential in excess of 100 MW.

Pricing programs and lighting Auto-DR for C&I customers, timed water heating programs, and behavioral DR compose the next tier of opportunities, with technical potential in each ranging between 50 and 100 MW. These programs generally have the potential to reach significant levels of enrollment or, alternatively, to provide deep load reductions among a smaller share of customers.

The Small C&I segment accounts for many of the DR programs with the lowest technical potential, as there is a relatively small share of load in this segment and these customers have historically demonstrated a lower willingness to participate in DR programs.

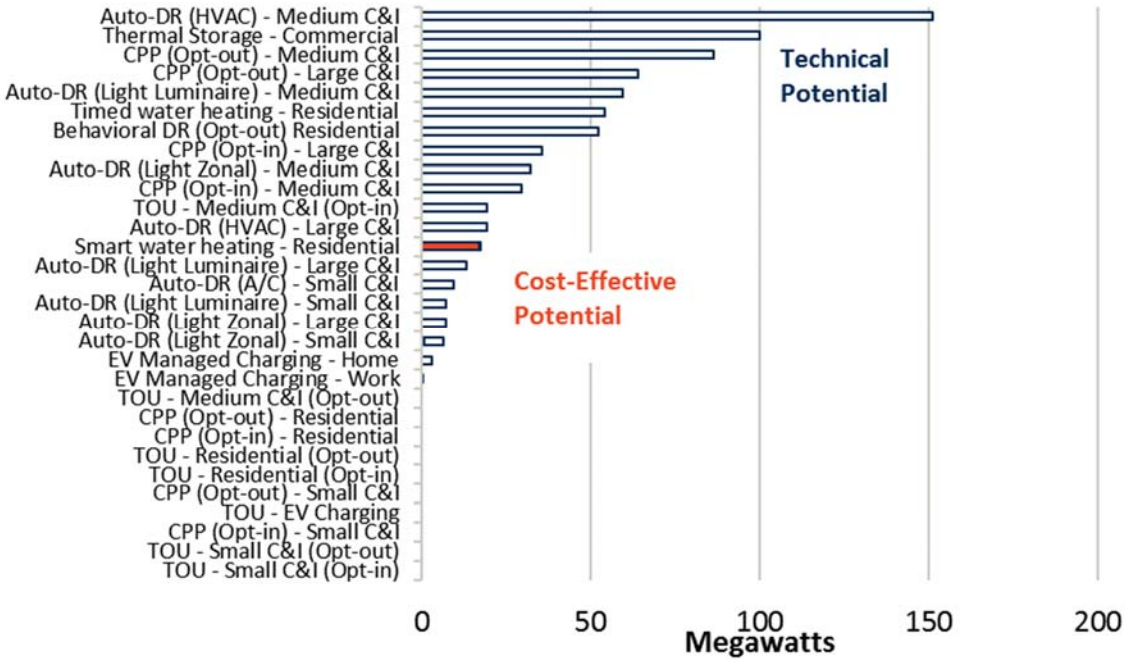
EV charging load control programs also have very modest technical potential in 2023. This is driven in part by a limited projection of EV adoption over the next five years. It is also driven by a lack of coincidence between peak charging load and the timing of the system peak.

Pricing programs (i.e., TOU, CPP) cannot be offered on a full scale basis in 2023 to residential and small C&I customers, as AMI will not yet be fully deployed. Therefore, pricing programs have not been included in the potential estimates for 2023. Rollout of the programs is assumed to begin in 2024, upon NSP's projected completion of the AMI rollout.

Programs with significant *technical potential* do not necessarily have significant *cost-effective potential*. After accounting for cost-effectiveness under Base Case market conditions as well as technical constraints, the potential in DR programs is limited in 2023. Individually, only smart water heating and a modest amount of automated load control for C&I customers pass the cost-effectiveness screen. These programs pass the cost-effectiveness screen largely because they are capable of providing an expanded array of value streams, such as frequency regulation and geo-targeted T&D deferral.

Figure 8 summarizes the technical and cost-effective potential in each of the new DR program options. Potential is first shown for DR programs as if they were each offered in isolation.

Figure 8: New DR Program Potential in 2023 (Base Case)

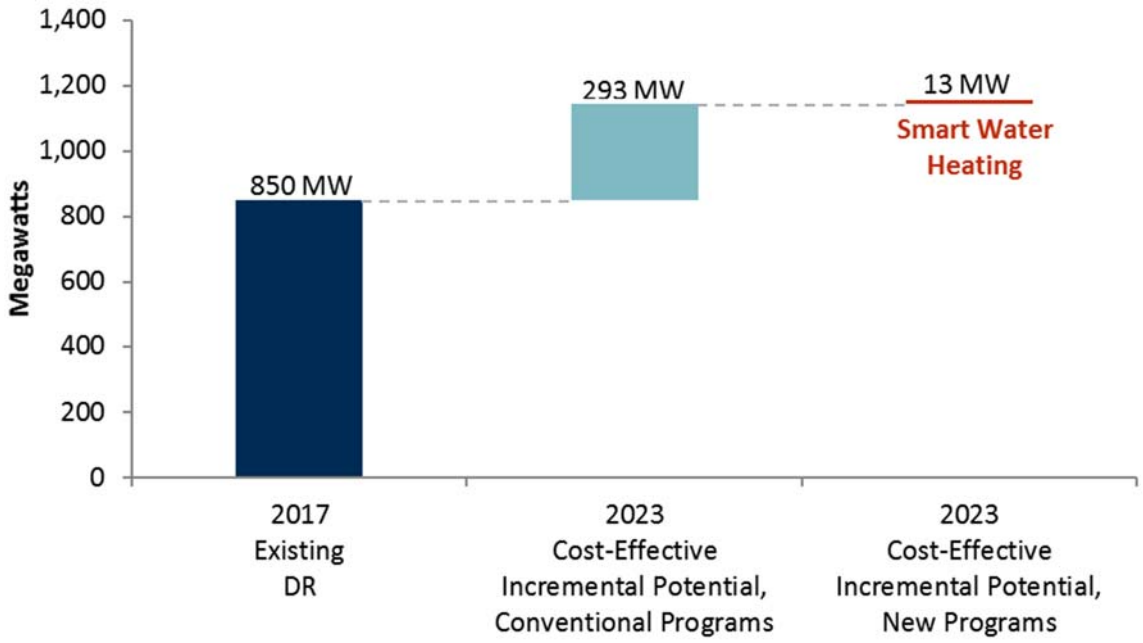


Note: Results reflect NSP system-wide DR potential. Impacts assume each program is offered in isolation; they are not additive. All potential is incremental to NSP's existing portfolio.

The program-level DR impacts shown above cannot be added together to arrive at the potential capability of a DR portfolio. Adjustments must be made to account for double-counting of impacts when customers are enrolled in more than one program, and for limits on the need for certain value streams such as frequency regulation. Thus, combining the cost-effective programs into a portfolio can result in lower total potential DR capability than if the individual impacts shown above were simply summed.

In the 2023 scenario described above, the smart water heating program alone could satisfy NSP's need for frequency regulation. With that value stream no longer available to the Auto-DR program, the Auto-DR program fails the cost-effectiveness screen. **With the addition of the smart water heating program, NSP's cost-effective DR portfolio would increase by 13 MW. Achievement of all cost-effective DR potential would amount to total system-wide DR capability of 1,156 MW, but would still fall short of the PUC's procurement target by 154 MW.** The expanded capability in 2023 is illustrated in Figure 9.

Figure 9: Total DR Potential in 2023 (Expanded Portfolio)



Near-term Limitations on DR Value

The value of DR is very dependent on the characteristics of the system in which it is deployed. Several factors limit NSP's cost-effective DR in 2023, relative to other jurisdictions.

- **Low capacity prices:** NSP has access to low-cost peaking capacity, primarily due to the presence of brownfield sites that significantly reduce development costs. For instance, the all-in cost of a new combustion turbine in NSP's IRP is $63/kW-year, which is 23 percent lower than the cost of a CT assumed by the U.S. Energy Information Administration (EIA) in its Annual Energy Outlook (AEO). Similarly, a recent study approved by the Minnesota PUC determined that the average value of T&D capacity deferral achieved through reductions in customer consumption is approximately $11/kW-year in NSP's service territory.[13] This value, which was determined through a detailed bottom-up engineering assessment, is significantly lower than that of T&D deferral benefits observed in other studies, which can commonly reach values of $30/kW-year.[14] The value of T&D deferral is dependent on characteristics of the utility system and drivers of the investment need, and therefore varies significantly across utilities.

[13] Xcel Energy, "Minnesota Transmission and Distribution Avoided Cost Study," submitted to the Minnesota Department of Commerce, Division of Energy Resources (Department), July 31, 2017

[14] Ryan Hledik and Ahmad Faruqui, "Valuing Demand Response: International Best Practices, Case Studies, and Applications," prepared for EnerNOC, January 2015.

- **Metering technology limitations:** NSP has not yet deployed AMI, with an estimated forecast that system-wide AMI installation will be completed in 2024. AMI-based DR programs, such as time-varying rates and behavioral DR, cannot be offered to customers until deployment is complete. This effectively excludes the possibility of introducing any AMI-based programs in the year 2023.

- **High DR technology costs:** Some emerging DR programs depend on new technologies that have not yet experienced the cost declines that could be achieved at scale. While these technology costs could decrease over time, those reductions are not achieved in the early years of the study horizon.

- **Limited need for additional DR value streams:** While certain DR value streams potentially can be very valuable, these value streams can also be limited in need. For instance, our analysis of NSP's five-year distribution plan identified only 38 MW of projects that were potential candidates for geo-targeted capacity investment deferral. Those projects accounted for roughly 10 percent of the total value of NSP's plan. To qualify, projects need to satisfy criteria such as being driven by growth in demand and being of a certain size.[15] Similarly, while frequency regulation is often a highly-valued ancillary service and can be provided by certain types of DR, the need for frequency regulation across most markets is significantly less than one percent of system peak demand. This limits the amount of that value stream that can be provided by DR.

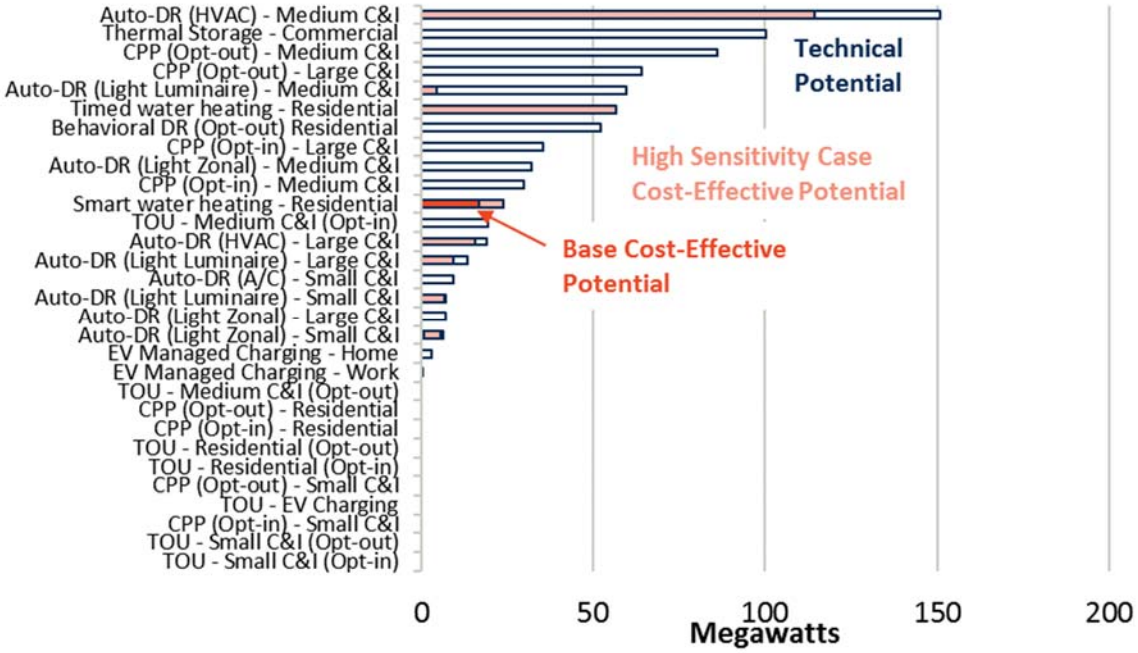
High Sensitivity Case

The High Sensitivity Case illustrates the potential for DR under an alternative set of market conditions that are more favorable to DR program economics. As discussed earlier in this report, assumptions behind the High Sensitivity Case are not a forecast of what is likely to happen in the future in NSP's service territory, particularly in the near-term years of the study horizon.

Under the illustrative High Sensitivity Case assumptions, cost-effective DR potential increases significantly. Several programs that were not previously passing the cost-effectiveness screen, such as medium C&I HVAC-based Auto DR, residential timed water heating, and a small amount of lighting-based Auto-DR do pass the screen under the more favorable assumptions in this case. Figure 10 summarizes the increase in cost-effective potential at the individual program level.

[15] Details of the geo-targeted T&D deferral analysis are included in Appendix A.

Figure 10: New DR Program Potential in 2023 (High Sensitivity Case)



Note: Results reflect NSP system-wide DR potential. Impacts assume each program is offered in isolation; they are not additive. All potential is incremental to NSP's existing portfolio.

A DR portfolio constructed from cost-effective programs in the High Sensitivity Case would produce total incremental DR potential of 484 MW in 2023. Under the illustrative assumptions in this case, the cost-effective incremental portfolio would consist of 393 MW of conventional DR programs, and 91 MW of new DR programs. The portfolio of new DR programs includes residential smart water heating [16] (24 MW) and C&I HVAC-based Auto-DR (67 MW). Achievement of all cost-effective DR potential under the High Sensitivity Case would amount to total system-wide DR capability of 1,334 MW.

[16] Smart water heating has lower cost-effective potential in 2023 than timed water heating. However, the smart water heating program provides more value and more significant per-participant impacts as participation ramps up in the later years of the study horizon, so it is the water heating program that was included in the portfolio.

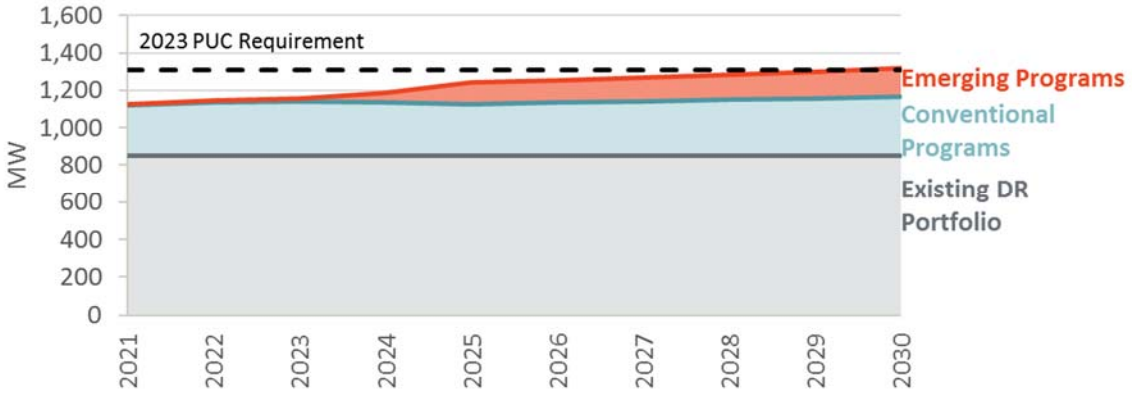
V. Expanded DR Potential in 2030

Base Case

Opportunities to expand cost-effective DR portfolio will grow beyond 2023. Most significantly, time-varying rates (such as TOU and CPP rates) can be offered to customers following completion of the AMI rollout in 2024. Additionally, the customer base is projected to grow over the study horizon, expanding the population of customers eligible to participation in DR programs. Growth in the market penetration of renewable generation will likely lead to more volatility in energy costs, further creating opportunities for DR to provide value. Additionally, current participants in the Savers Switch program are expected to transition to the smart thermostat-based A/C Reward program over time. Smart thermostats provide a greater per-participant demand reduction than the technology in the Savers Switch program, therefore further increasing DR potential.

Figure 11 summarizes growth in DR potential under Base Case assumptions for the portfolio of cost-effective DR programs. The majority of the post-2023 growth comes from the introduction of time-varying pricing programs.

Figure 11: Cost-Effective DR Potential, Base Case



Under Base Case conditions, benefits of the DR program are primarily driven by avoided generation capacity costs. Avoided generation capacity costs account for $51 million of the $66 million (77 percent) in total annual benefits from the DR programs in the year 2030. This is because the relatively low avoided costs in the Base Case scenario tend to favor conventional DR programs which are primarily constrained to reducing the system peak, but have lower costs as a result of this somewhat limited functionality. Table 4 summarizes the annual benefits, by category, of the incremental cost-effective DR portfolio in 2030 for the Base Case.

Table 4: Annual Avoided Costs from 2030 DR Portfolio, Base Case ($ million/year)

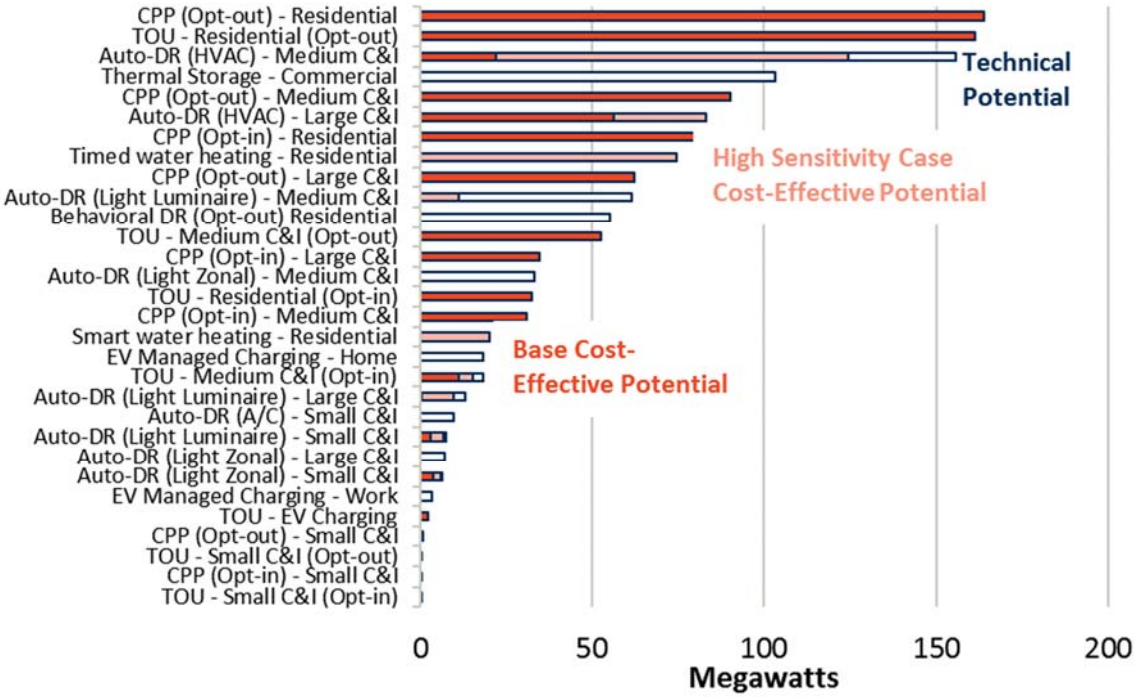
	Energy	Generation Capacity	System Average T&D Deferral	Geotargeted Distribution Deferral	Frequency Regulation	Total
Conventional Programs	$5.0	$43.6	$2.8	$0.0	$0.0	$51.4
Emerging Programs	$5.7	$7.4	$0.4	$0.0	$1.2	$14.7
Total	$10.7	$50.9	$3.2	$0.0	$1.2	$66.1

Notes: Benefits shown in 2023 dollars. Estimates include benefits from NSP's existing 850 MW portfolio.

High Sensitivity Case

Drivers of growth over time under the illustrative High Sensitivity Case conditions are similar to growth drivers under Base Case conditions, with AMI-enabled time-varying rates accounting for the majority of new opportunities after 2023. Figure 12 summarizes the 2030 incremental measure-level potential for both the Base Case and the High Sensitivity Case.

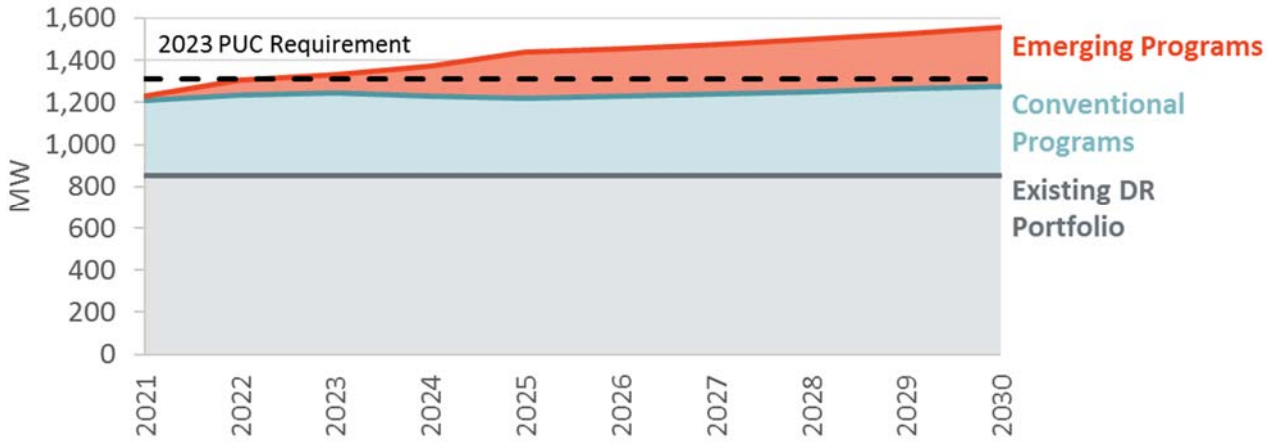
Figure 12: New DR Program Potential in 2030



Note: Results reflect NSP system-wide DR potential. Impacts assume each program is offered in isolation; they are not additive. All potential is incremental to NSP's existing portfolio.

The capability of the cost-effective DR portfolio for the High Sensitivity Case is summarized in Figure 13.

Figure 13: Cost-Effective DR Potential, High Sensitivity Case



Over the longer-term, new policies could potentially drive down DR costs and therefore increase cost-effective potential. One initiative that has garnered some attention is the development of a technology standard known as "CTA-2045." CTA-2045 is a communications interface which would allow various control technologies to connect to appliances through a standard port or socket. While widespread adoption of this standard is not considered to be imminent, it could potentially have positive implications for DR adoption in the longer term. See the Sidebar at the end of this section for further discussion of the outlook for CTA-2045.

The benefits of DR under the High Sensitivity Case assumptions continue to be driven primarily by avoided generation capacity costs. However, additional price volatility due a greater assumed mix of renewable generation in the regional supply portfolio leads to an increase in the share of total that is attributable to avoided energy costs. The total value of frequency regulation provided by DR also increases modestly relative to the Base Case, as a greater need for this service is assumed for renewable generation integration purposes. Table 5 summarizes the annual benefits, by category, of the incremental cost-effective DR portfolio in 2030 for the High Sensitivity Case.

Table 5: Annual Avoided Costs from 2030 DR Portfolio, High Sensitivity Case ($ million/year)

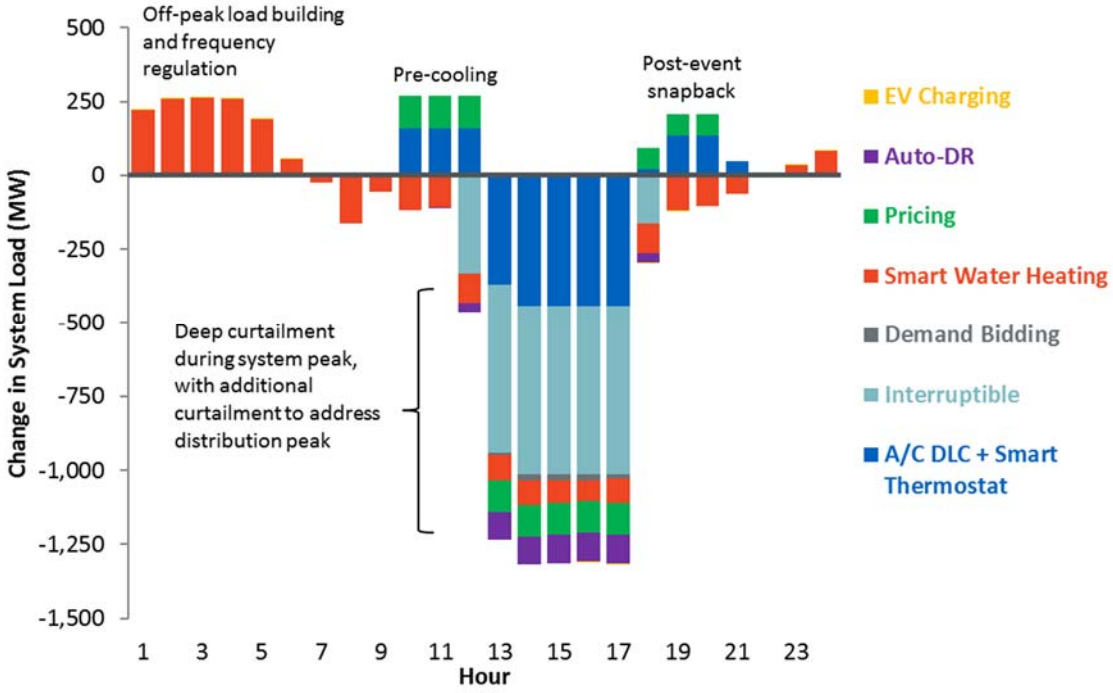
	Energy	Generation Capacity	System Average T&D Deferral	Geotargeted Distribution Deferral	Frequency Regulation	Total
Conventional Programs	$8.6	$69.7	$3.3	$0.0	$0.0	$81.5
Emerging Programs	$19.6	$19.5	$0.8	$0.7	$4.6	$45.2
Total	$28.2	$89.2	$4.0	$0.7	$4.6	$126.8

Notes: Benefits shown in 2023 dollars. Estimates include benefits from NSP's existing 850 MW portfolio.

DR Portfolio Operation

The addition of emerging programs to NSP's DR portfolio will improve operational flexibility across NSP's system. Figure 14 illustrates how the cost-effective DR portfolio from the High Sensitivity Case could operate on an hourly basis during the days of the year with the highest system peak demand. The profile shown maximizes avoided costs relative to the system cost assumptions used in this study.

Figure 14: Average Load Impacts of the 2030 Cost-Effective DR Portfolio on Top 10 Load Days (High Sensitivity Case)



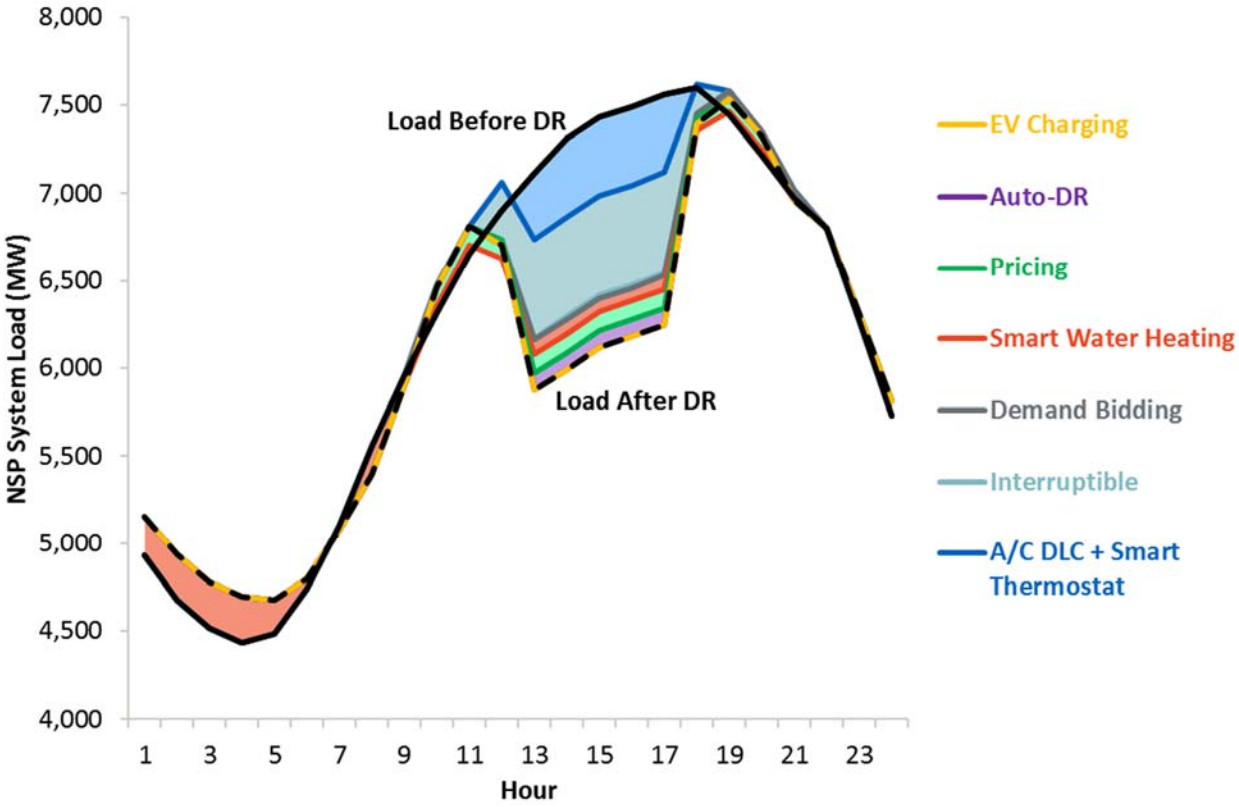
Note: Shown for cost-effective programs identified in 2030, accounting for portfolio overlap.

A deep curtailment of load during system peak hours is utilized to capture significant generation and T&D capacity deferral benefits. These also tend to be hours when energy costs are highest, leading to additional energy value. The duration of the peak load curtailment spans a fairly broad period of time – seven hours – in order to account for the lack of coincidence of the system and local peak demand that drive capacity needs. Load curtailment can be staggered across DR programs – and across participants in a given DR program – in order to achieve this duration of demand reduction.

Load increases are observed immediately before and after the peak load reduction. This is driven mostly by the need to maintain and restore building temperatures to desired levels around DR events. The smart water heating program builds load during nighttime hours, shifting heating load to the lowest cost hours and potentially reducing the curtailment of renewable generation.

Figure 15 illustrates how NSP's system load shape changes as a result of the impacts shown in Figure 14 above. The figure shows a steep reduction in load during hours of the MISO system peak, while NSP's later peak is only modestly reduced. This is primarily due to NSP's planning needs being driven by MISO coincident peak demand. If the MISO peak shifts later in the day due to solar PV adoption, or if NSP transitions to an increased focus on its own peak demand in planning activities, then the dispatch of the DR programs would need to be modified accordingly. In particular, it may become necessary to stagger the utilization of DR programs across a broader window of hours in order to "flatten" peak demand across the hours of the day.

Figure 15: Average Impacts of the 2030 Cost-Effective DR Portfolio on NSP System Load (High Sensitivity Case)



Note: Shown for cost-effective programs identified in 2030, accounting for portfolio overlap.

Sidebar: The Outlook for CTA-2045

CTA-2045 is a standard which specifies a low-cost communications "socket" that would be embedded in electric appliances and other consumer products. If consumers wished to make an appliance capable of participating in a demand response program, they could simply plug a communications receiver into the socket, thus allowing the appliance to be controlled by themselves or a third party. CTA-2045 has the potential to establish a low-cost option for two-way communications capability in appliances, thus reducing the cost and hassle of consumer enrollment in DR programs that would otherwise require on-site installation of more costly equipment.

Development of CTA-2045 began in 2011, through work by the Consumer Technology Association (CTA) and the Electric Power Research Institute (EPRI). Refinements to the standard are ongoing. To assess the outlook for CTA-2045 and its potential implications for future DR efforts, we conducted phone and email interviews with subject matter experts from utilities, appliance manufacturers, and DR software platforms.

There is a shared view that CTA-2045 is facing a chicken-and-egg problem. Manufacturers have been hesitant to incorporate the standard into their products, because there is a cost associated with doing so and they have not yet observed demand in the market for the communications functionality. At the same time, a barrier preventing increased adoption of DR technologies could be some of the costs and installation challenges that CTA-2045 would ultimately address.

Products with CTA-2045 functionality have not yet been deployed at scale, and where available are sold at a price premium that is significantly higher than the unit costs that could ultimately be achieved at scale. The relative lack of enthusiasm among manufacturers for rolling out CTA-2045 compliant products has led to a slow pace of development of the standard itself. Progress is being made incrementally, though technical issues still remain to be resolved.

Looking forward, some in the industry feel that the mandating CTA-2045 through a new state appliance standard could be the catalyst that is needed for adoption to become broadly widespread. Aggressive support for CTA-2045 by large utilities is also considered to be the type of activity that would facilitate adoption.

If compliance with CTA-2045 ultimately were to accelerate through activities like those described above, electric water heaters are poised to become the first such commercial application, as they have been the most common test case for proving the technical concept and are an attractive source of load flexibility. Particularly in the context of water heaters, CTA-2045 would help to overcome the challenge of enrolling customers in a DR program during the very narrow window of time during which their existing water heater expires and must be replaced. Other controllable end-uses, such as thermostats or even electric vehicle chargers could be candidates for the standard, though these technologies sometimes already come pre-equipped with communications capabilities.

VI. Conclusions and Recommendations

NSP's sizeable existing DR portfolio has the potential to be expanded by tapping into latent demand for existing programs and also by rolling out a new portfolio of emerging DR programs. Specific recommendations for acting on the findings of this study including the following:

Aggressively pursue the transition to smart thermostats as well as recruitment of medium C&I customers into a redesigned Interruptible program. NSP's relatively low avoided costs mean that lower cost, established DR programs are the most economically attractive options in the near term. Smart thermostats and a modernized Medium C&I interruptible program present the largest incremental opportunity and the least amount of uncertainty/risk.

Pilot and deploy a smart water heating program. There is significant experience with advanced water heating load control in the Upper Midwest, and the technology is rapidly advancing. The thermal storage capabilities of water heaters provide a high degree of load flexibility that can be adapted to a range of system needs.

As a complementary activity to the development of a smart water heating program, also evaluate the economics and environmental impacts of switching from gas to electric heating, factoring in the grid reliability benefits associated with this flexible source of load. Doing so would require revisiting existing state policies that prohibit utility-incentivized fuel switching.

Build the foundation for a robust offering of time-varying rates. As a first step, prepare a strategy for rolling out innovative rates soon after AMI is deployed. This should include exploring rate offerings that could be deployed to customers on a default (opt-out) basis, as default rate offerings maximize the overall economic benefit for the program.

Develop measurement & verification (M&V) 2.0 protocols to ensure that the impacts of the program are dependable and can be integrated meaningfully into resource planning efforts. Included in this initiative could be the development of a data collection plan to enhance the quality of future market potential studies. Further, detailed customer segmentation and geographically granular load data at the distribution system level will provide an improved base from which to develop a cost-effective DR strategy.

Design programs with peak period flexibility. From a planning standpoint, the timing of the peak period could change for a variety of reasons (e.g., DR flattens the peak, solar PV shifts the net peak, or the planning emphasis shifts from a focus on the MISO peak to a focus on more local peaks). DR programs will need to be designed with the flexibility to adjust the timing of curtailments in response to these changes.

Appendix A: Load*Flex* Modeling Methodology and Assumptions

The Load*Flex* Model

The Brattle Group's Load*Flex* model was developed to quantify the potential impacts, costs, and benefits of demand response (DR) programs. The Load*Flex* modeling approach offers the flexibility to accurately estimate the broader range of benefits that are being offered by emerging "DR 2.0" programs which not only reduce system peak demand, but also provide around-the-clock load management opportunities.

The Load*Flex* modeling framework builds upon the standard approach to quantifying DR potential that has been used in prior studies around the U.S. and internationally, but incorporates a number of differentiating features which allow for a more robust evaluation of DR programs:

- **Economically optimized enrollment:** Assumed participation in DR programs is tailored to the incentive payment levels that are cost-effective for the DR program. If only a modest incentive payment can be justified in order to maintain a benefit-cost ratio of 1.0, then the participation rate is calibrated to be lower than if a more lucrative incentive payment were offered. Prior approaches to quantifying DR potential ignore this relationship between incentive payment level and participation, which tends to under-state the potential (and, in some cases, incorrectly concludes that a DR program would not pass the cost-effectiveness screen).

- **Utility-calibrated load impacts:** Load impacts are calibrated to the characteristics of the utility's customer base. In the residential sector, this includes accounting for the market saturation of various end-use appliances (e.g., central air-conditioning, electric water heating). In the commercial and industrial (C&I) sector, this includes accounting for customer segmentation based on size (i.e., the customer's maximum demand) and industry (e.g., hospital, university). Load curtailment capability is further calibrated to the utility's experience with DR programs (e.g., impacts from existing DLC programs or dynamic pricing pilots).

- **Sophisticated DR program dispatch:** DR program dispatch is optimized subject to detailed accounting for the operational constraints of the program. In addition to tariff-related program limitations (e.g., how often the program can be called, hours of the day when it can be called), Load*Flex* includes an hourly profile of load interruption capability for each program. For instance, for an EV home charging load control program, the model accounts for home charging patterns, which would provide greater average load reduction

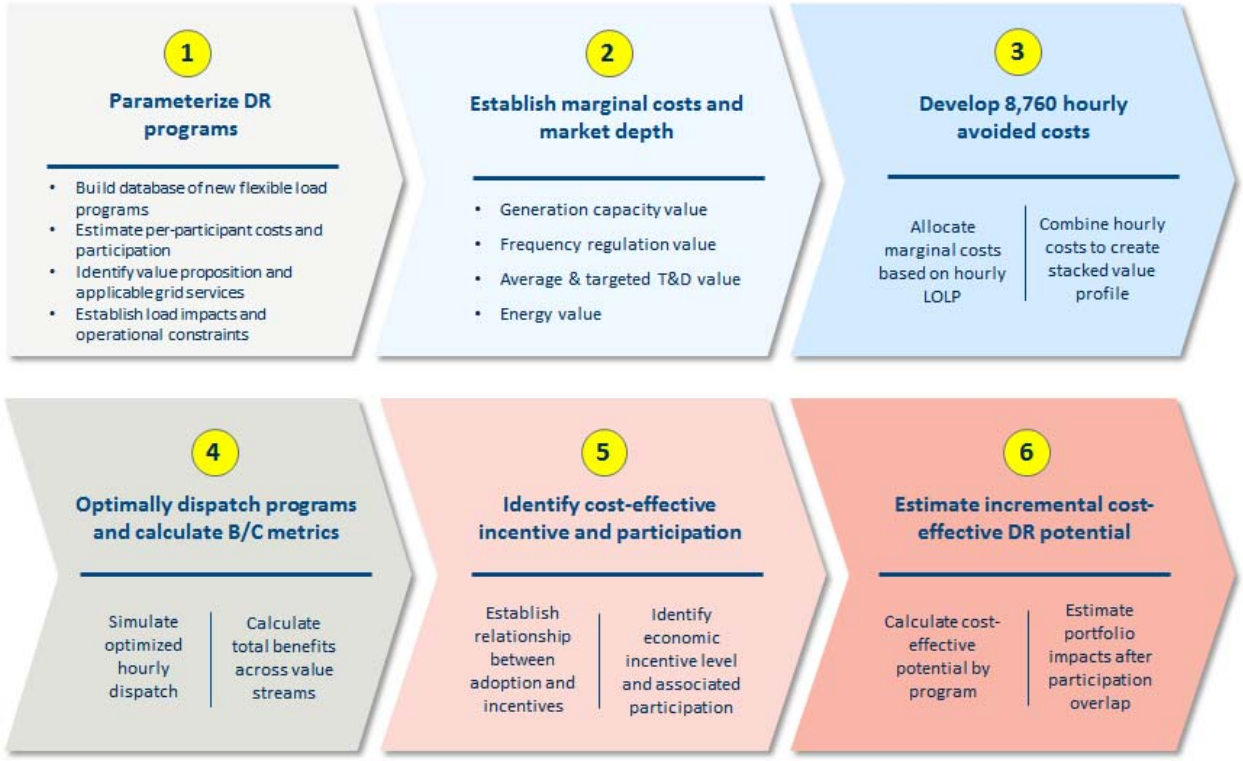
opportunities during evening hours (when EV owners have returned home from work) than in the middle of the day.

- **Realistic accounting for "value stacking":** DR programs have the potential to simultaneously provide multiple benefits. For instance, a DR program that is dispatched to reduce the system peak and therefore avoid generation capacity costs could also be dispatched to address local distribution system constraints. However, tradeoffs must be made in pursuing these value streams – curtailing load during certain hours of the day may prohibit that same load from being curtailed again later in the day for a different purpose. Load*Flex* accounts for these tradeoffs in its DR dispatch algorithm. DR program operations are simulated to maximize total benefits across multiple value streams, while recognizing the operational constraints of the program. Prior studies have often assigned multiple benefits to DR programs without accounting for these tradeoffs, thus double-counting benefits.

- **Industry-validated program costs:** DR program costs are based on a detailed review of the utility's current DR offerings. For new programs, costs are based on a review of experience and studies in other jurisdictions and conversations with vendors. Program costs are differentiated by type (e.g., equipment/installation, administrative) and structure (e.g., one-time investment, ongoing annual fee, per-kilowatt fee) to facilitate integration into utility resource planning models.

The Load*Flex* methodology is organized around six steps, as summarized in Figure 16. The remainder of this appendix describes each of the six steps in further detail, documenting methodology, assumptions, and data sources.

Figure 16: The Load*Flex* Modeling Framework



Step 1: Parameterize the DR programs

Each DR program is represented according to two broad categories of characteristics: Performance characteristics and cost characteristics.

Program Performance Characteristics

The performance characteristics of each DR program are represented in detail in Load*Flex* to accurately estimate the ability of the DR programs to provide system value. The following are key aspects of each program's performance capability.

Load impact profiles

Each DR program is represented with 24-hour average daily profiles of load reduction and load increase capability. These 24-hour impact profiles are differentiated by season (summer, winter, shoulder) and day type (weekday, weekend). For instance, air-conditioning load curtailment capability is highest during daytime hours in the summer, lower during nighttime summer hours, and non-existent during all hours in the winter.

Whenever possible, load impacts are derived directly from NSP's experience with its existing DR programs and pilots. NSP's experience directly informed the impact estimates for direct load control, smart thermostat, and interruptible rates programs. For emerging non-pricing DR

programs, impacts are based on a review of experience and studies in other jurisdictions and tailored to NSP's customer mix and climate. Methods used to develop impact profile estimates for emerging non-pricing DR programs include the following:

- *C&I Auto-DR:* The potential for C&I customers to provide around-the-clock load flexibility was primarily derived from data supporting a 2017 statewide assessment of DR potential in California[17], a 2013 LBNL study of DR capability[18], and electricity load patterns representative of C&I buildings in Minneapolis developed by the Department of Energy.[19] Customer segment-specific estimates from these studies were combined to produce a composite load impact profile for the NSP service territory based on assumptions about NSP's mix of C&I customers. Impacts were scaled as necessary for consistency with NSP's prior experience with C&I DR programs.

- *Water heating load control:* Assumptions for the water heating load control programs – both grid interactive water heating and static timed water heating - are derived from a 2016 study on the value of various water heating load control strategies.[20] The program definition assumes that only customers with existing electric resistance water heaters will be eligible for participating in the water heating programs.

- *Behavioral DR:* Impacts are derived from a review of the findings of behavioral DR pilot studies conducted around the US, including for Baltimore Gas & Electric, Consumers Energy, Green Mountain Power, Glendale Water and Power, Portland Gas Electric, and Pacific Gas and Electric. Most behavioral DR pilot studies have been conducted by Oracle (OPower) and have generally found that programs with a limited number of short curtailment events (4-10 events for 3-5 afternoon/evening hours) can achieve 2% to 3% load reduction across enrolled customers.[21] Based on these findings, we assumed that a

21 For example, see Jonathan Cook et al., "Behavioral Demand Response Study – Load Impact Evaluation Report", January 11, 2016, prepared for Pacific Gas & Electric Company, available at: http://www.oracle.com/us/industries/utilities/behavioral-demand-response-3628982.pdf, and OPower,

behavioral DR program called 10 times per year between 3 pm and 6 pm would achieve a 2.5% load reduction.

- *EV managed charging:* Estimates of load curtailment capability are based on projections of aggregate EV charging load shapes provided by Xcel Energy. The ability to curtail this charging load is based on a review of recent utility EV charging DR pilots, including managed charging programs at several California utilities (PG&E, SDG&E, SCE, and SMUD) and United Energy in Australia.[22]

- *Ice-based thermal energy storage:* Estimates of load curtailment capability are estimated based on charging and discharging (freezing and cooling) information from Ice Bear[23] and adapted to mirror building use patterns in Minnesota based on load profiles from the U.S. Department of Energy.[24]

For impacts from pricing programs, we relied on Brattle's database of time-varying pricing offerings. The database includes the results of more than 300 experimental and non-experimental pricing treatments across over 60 pilot programs.[25] It includes published results from Xcel Energy's various pricing pilots during this time period. The results of the pilots in the database are used to establish a relationship between the peak-to-off-peak price ratio of the rates and the average load reduction per participant, in order to simulate price response associated with any given rate design. This relationship between load reduction and price ratio is illustrated in Figure 17.

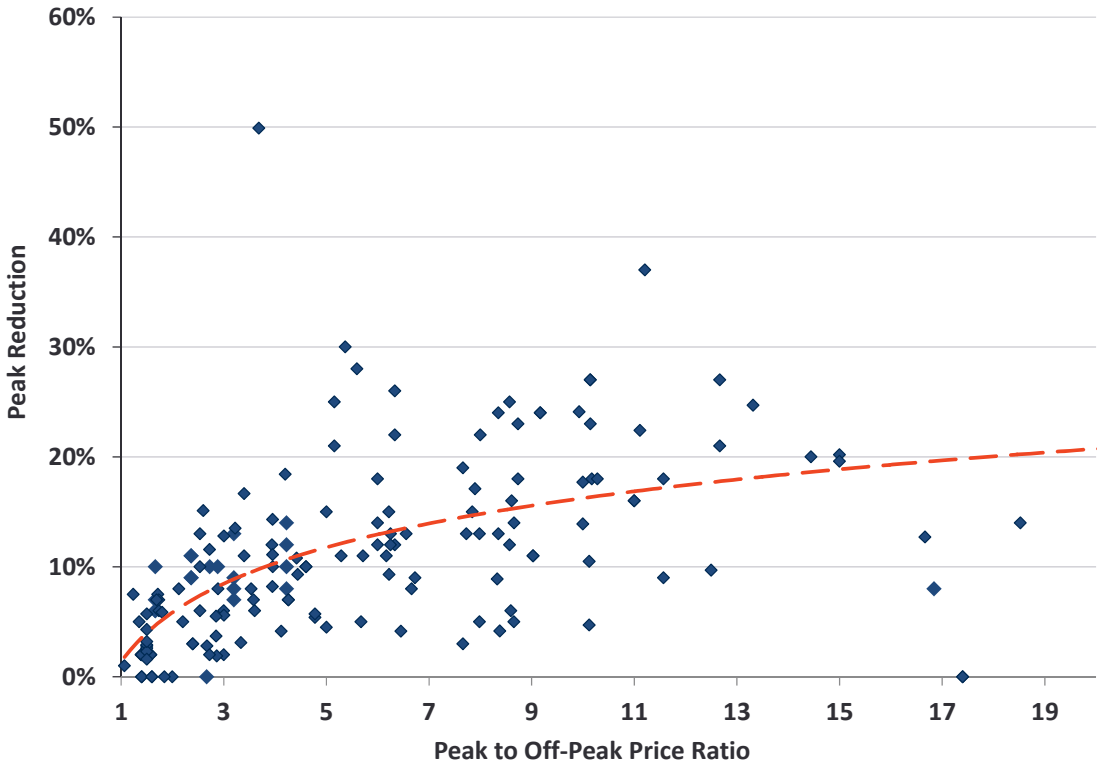
Figure 17: Relationship between Price Ratio and Price Response in Residential Pricing Pilots



Results shown only for price ratios less than 20-to-1 and for treatments that did not include automating technology such as smart thermostats.

Daily relationship between load reduction and load increase

Some DR programs will require a load increase to offset or partially offset the load that is reduced during a curtailment event. In Load*Flex*, each program definition includes a parameter that represents the percent of curtailed load that must be offset by increased load on the same day, including the timing of when the load increase must occur. For instance, in a water heating load control program, any reduction in water heating load is assumed to be offset by an equal increase in water heating load on the same day in order to meet the customer's water heating needs. Alternatively, a reduction in air-conditioning load may only be offset partially by an increase in consumption, but it would immediately follow the curtailment.

Where data is available, these load building assumptions are based on the same data sources described above. Otherwise, these impacts are derived from assumptions that were developed for FERC's 2009 *A National Assessment of Demand Response Potential*.

Tariff-related operational constraints

Most DR programs will have administrator-defined limits on the operation of the program. This includes the maximum number of hours per day that the program can be curtailed, whether or not those curtailment hours must be contiguous, and the maximum number of days per year with

allowed curtailment. Assumed operational constraints are based on Xcel Energy's program definitions and a review of common limitations from programs offered in other jurisdictions.

Ancillary services availability

If a DR program has the advanced control and communications technology necessary to provide ancillary services, Load*Flex* accounts for the capacity that is available to provide fast-response load increases or decreases in response to real-time fluctuations in supply and demand. In this study, smart water heating and Auto-DR are assumed to be able to offer ancillary services. Specifically, we model frequency regulation as it is the most valuable ancillary services product. Capability is based on the same data sources described above.

Table 6 summarizes the performance characteristics for each DR program in this study. In the table, "load shifting capability" identifies whether or not a program is capable of shifting energy usage from peak periods to off-peak periods on a daily basis.

Table 6: DR Program Performance Characteristics

Segment	Program	Peak-coincident curtailment capability (kW/participant)	Hours of Curtailment (hours)	Average regulation up provided (kW/participant)	Average regulation down provided (kW/participant)	Load shifting capability?

Notes:
Program impacts shown reflect impacts for new participants. Impacts shown assume each program is offered independently.

Program Cost Characteristics

The costs of each program include startup costs, marketing and customer recruitment, the utility's share of equipment and installation costs, program administration and overhead, churn costs (i.e., the annual cost of replacing participants that leave the program), and participation incentives.[26]

[26] The Utility Cost Test (UCT) is the cost-effectiveness screen used in this study, which calls for including incentive payments as a cost.

Cost assumptions are based on NSP's current program costs, where applicable. Otherwise, costs are based on a review of experience and studies in other jurisdictions and conversations with vendors, and are tailored for consistency with NSP's current program costs. Notable assumptions in developing the cost estimates include the following:

- Water heating technology costs include the cost of the load control and communications equipment and the *incremental* cost of replacing the existing water heater (50-gallon average) with a larger water heater (80-gallon) when the existing water heater expires. The full cost of a new water heater is not assigned to the program.

- Similarly, EV charging load control equipment costs include the incremental cost of load control and communications technology, but not the full cost of a charging unit.

- The cost of AMI is not counted against any of the DR programs, as it is treated as a sunk cost that is likely to be justified by a broad range of benefits that the new digital infrastructure will provides to customers and to NSP. However, a rough estimate of the cost of IT and billing system upgrades specifically associated with offering time-varying pricing programs are included in the costs for those programs.

- The cost of advanced lighting control systems is not counted against DR programs as these control systems are typically installed for non-energy benefits.

Table 7 summarizes Base Case cost assumptions for 2023 and Table 8 summarizes High Sensitivity Case cost assumptions for 2030. The 2030 assumptions reflect an assumed 25% reduction in the cost (in real terms) of emerging technologies. Costs in both tables are shown in nominal dollars. As discussed later in this appendix, the "base" incentive levels are derived from commonly observed payments both by NSP and in other jurisdictions. They do not reflect the cost-effective incentive payment levels that are ultimately established through the modeling.

Table 7: 2023 Base Case Program Cost Assumptions

		One-Time Costs			Recurring Costs			
Segment	Program	Fixed Cost ($)	Variable Equipment Cost ($/participant)	Other Initial Costs ($/participant)	Fixed Admin & Other ($/year)	Variable Admin & Other ($/participant-year)	Base Annual Incentive Level ($/participant-year)	Economic Life (years)

Notes:
2030 one-time costs assumed to be 30% lower than 2023 one-time costs (in real terms), reflecting assumed declines in technology costs. All costs shown in nominal dollars. Variable equipment cost and other initial costs include 2.5% churn cost adder. Analysis assumes a 6.44% discount rate for annualizing one-time costs.

Step 2: Establish system marginal costs and quantity of system need

Load*Flex* was used to quantify a broad range of value streams that could be provided by DR. These include avoided generation capacity costs, avoided system-wide T&D costs, additional avoided distribution costs from geo-targeted deployment of the DR programs, frequency regulation, and net avoided marginal energy costs.

The system costs that could be avoided through DR deployment are estimated based on market data that is specific to NSP's service territory. Assumptions used in developing each marginal (i.e., avoidable) cost estimate are described in more detail below, for both the Base Case and the High Sensitivity Case.

Avoided generation capacity costs

DR programs are most appropriately recognized as substitutes for new combustion turbine (CT) capacity. CTs are "peaking" units with relatively low up-front installation costs and high variable costs. As a result, they typically only run up to a few hundred hours of the year, when electricity demand is very high and/or there are system reliability concerns. Similarly, use of DR programs in the U.S. is typically limited to less than 100 hours per year. This constraint is either written into the DR program tariff or is otherwise a practical consideration to avoid customer fatigue and program drop-outs.

In contrast, new intermediate or baseload capacity (e.g., gas-fired combined cycle) has a higher capital cost and lower variable cost than a CT, and therefore could run for thousands of hours per year. The DR programs considered in this study cannot feasibly avoid the need for new intermediate or baseload capacity, because they cannot be called during a sufficient number of hours of the year. Energy efficiency is a more comparable demand-side alternative to these resource types since it is a permanent load reduction that applies to a much broader range of hours.

In the Base Case, the installed cost of new CT capacity is based on data provided directly by NSP and consistent with the assumptions in NSP's 2019 IRP for a brownfield CT. The total cost amounts to $60.60/kW-year; this is sometimes referred to the gross cost of new entry (CONE). The gross CONE value is adjusted downward to account for the energy and ancillary services value that would otherwise be provided by that unit. Based on simulated unit profit data provided by NSP, we have estimated the annual energy and ancillary services value to be roughly $5.50/kW-year. The resulting net CONE value is $55.20/kW-year. This calculation is described further in Table 9 below.

This same approach is used to establish the capacity cost for the High Sensitivity Case. Rather than using the CT cost from NSP's IRP, we relied on the U.S. Energy Information Administration's (EIA's) estimate of the installed cost of an Advanced CT from the 2018 Annual Energy Outlook. For the Midwest Reliability Organization West region, this amounts to a gross CONE of $76.80/kW-year. Reducing this value by the same energy and ancillary services value described above leads to a net CONE of $71.40/kW-year.

Table 9: Combustion Turbine Cost of New Entry Calculation

Variable		NSP 2019 IRP Brownfield CT	NSP 2019 IRP Greenfield CT	AEO 2018 Advanced CT
Overnight Capital Cost ($/kW)	[1]	$467	$617	$698
Effective Charge Rate (%)	[2]	10%	10%	10%
Levelized Capital Cost ($/kW-yr)	[3]=[1]x[2]	$46.7	$61.7	$69.8
Annual Fixed Costs ($/kW-yr)	[4]	$13.9	$13.9	$7.0
Gross Cost of New Entry ($/kW-yr)	[5]=[3]+[4]	$60.6	$75.6	$76.8
E&AS Margins ($/kW-yr)	[6]	$5.5	$5.5	$5.5
Net Cost of New Entry ($/kW-yr)	[7]=[5]-[6]	$55.2	$70.2	$71.4

Notes: All costs shown in 2018 dollars. Assumes that overnight capital costs are recovered at 10% effective charge rate. AEO 2018 advanced CT costs shown for the Midwest Reliability Organization West region. Capacity costs are held constant in real terms throughout the period of study.

DR produces a reduction in consumption at the customer's premise (i.e. at the meter). Due energy losses on transmission and distribution lines as electricity is delivered from power plants to customer premises, a reduction in one kilowatt of demand at the meter avoids more than one kilowatt of generation capacity. In other words, assuming line losses of 8% percent, a power plant must generate 1.08 kW in order to deliver 1 kW to an individual premise.[27] When estimating the avoided capacity cost of DR, the avoided cost is grossed up to account for this factor. For this study, Xcel Energy provided load data at the generator level, thus already accounting for line loss gross-up.

Similarly, NSP incorporates a planning reserve margin of 2.4% percent into its capacity investment decisions.[28] This effectively means NSP will plan to have enough capacity available to meet its projected peak demand plus 2.4% percent of that value. In this sense, a reduction of one kilowatt at the meter level reduces the need for 1.024 kW of capacity. Including the 2.4% reserve margin adjustment increases the net CONE value described above from $55.2 and $71.4/kW-year to $56.5 and $73.1/kW-year, for the Base and High Sensitivity Cases respectively. This is the generation capacity value that could be provided by DR if it were to operate exactly like a CT.

Avoided transmission capacity costs

Reductions in system peak demand may also reduce the need for transmission upgrades. A portion of transmission investment is driven by the need to have enough capacity available to move electricity to where it is needed during peak times while maintaining a sufficient level of

[27] 8% represents an average line loss across NSP territories and customer segments. Actual line losses range from 2 to 10%.

[28] NSP's planning reserve margin target is 7.8% of load during the MISO peak, which translates into a margin of 2.4% during its own system peak.

reliability. Other transmission investments will not be peak related, but rather are intended to extend the grid to remotely located sources of generation, or to address constraints during mid- or off-peak periods. Based on the findings of NSP's 2017 T&D Avoided Cost Study for energy efficiency programs, we have assumed an avoidable transmission cost of $3.10/kW-year in 2023, rising to $3.60/kW-year in 2030.[29]

Avoided system-wide distribution capacity costs

Similar to transmission value, there may be long-term distribution capacity investment avoidance value associated with reductions in peak demand across the NSP system. For programs that do not provide the higher-value distribution benefits from geo-targeted deployment, as described below, we have assumed that peak demand reductions can produce avoided distribution costs of $8.10/kW-year in 2023, rising to $9.50/kW-year in 2030, based on NSP's 2017 T&D Avoided Cost Study.

Geo-targeted distribution capacity costs

DR participants may be recruited in locations on the distribution system where load reductions would defer the need for local capacity upgrades. This local deployment of the DR program can be targeted at specifically locations where distribution upgrades are expected to be costly.

DR cannot serve as a substitute for distribution upgrades in all cases, such as adding new circuit breakers, telemetry upgrades, or adding distribution lines to connect new customers. However, in many cases, system upgrades are needed to meet anticipated gradual load growth in a local area. At times, system planners must over-size distribution investments relative to the immediate needs to meet local load to allow for future load growth or utilize equipment (such as transformers) that only comes in certain standard sizes. To the extent that DR can be used to reduce local peak loads, the loading on the distribution system is reduced, which means otherwise necessary distribution upgrades may be deferred. Such deferrals are especially valuable if load growth is relatively slow and predictable such that the upgraded system would not be fully utilized for many years.

To quantify geo-targeted distribution capacity deferral value in Load*Flex*, we began with a list of all distribution capacity projects in NSP's five-year plan. Brattle worked with NSP staff to reduce this list to a subset of projects that are likely candidates for deferral through DR. Four criteria were applied to identify the list of candidate deferral projects:

1. The need for the distribution project must be driven by load growth. DR could not be used to avoid the need to simply replace aging equipment, for example.

[29] Xcel Energy, Minnesota Power, Otter Tail Power Company, Mendota Group & Environmental Economics, "Minnesota Transmission and Distribution Avoided Cost Study," July 31, 2017.

2. The project must have a meaningful overall cost on a per-kilowatt basis. In our analysis, we required that the cost of the project equate to a value of at least $100,000 per megawatt of reduced demand in order to be considered.[30] This is the equivalent of roughly $7/kW-year on an annualized basis. Projects below this cost threshold were excluded from the geo-targeted deferral analysis.

3. There must be sufficient local customer load in order for the upgrade to be deferrable through the use of DR. For instance, if a 20 MW load reduction would be needed to avoid a specific distribution upgrade, and there was only 25 MW of total load at that location in the system, then DR would not be a useful candidate because it is unlikely that DR could consistently and reliably produce an 80% load reduction. In establishing this criterion, projects with more than 6 MVA of "load at risk"[31] were excluded, as 6 MVA represents about half of the load on a typical feeder.

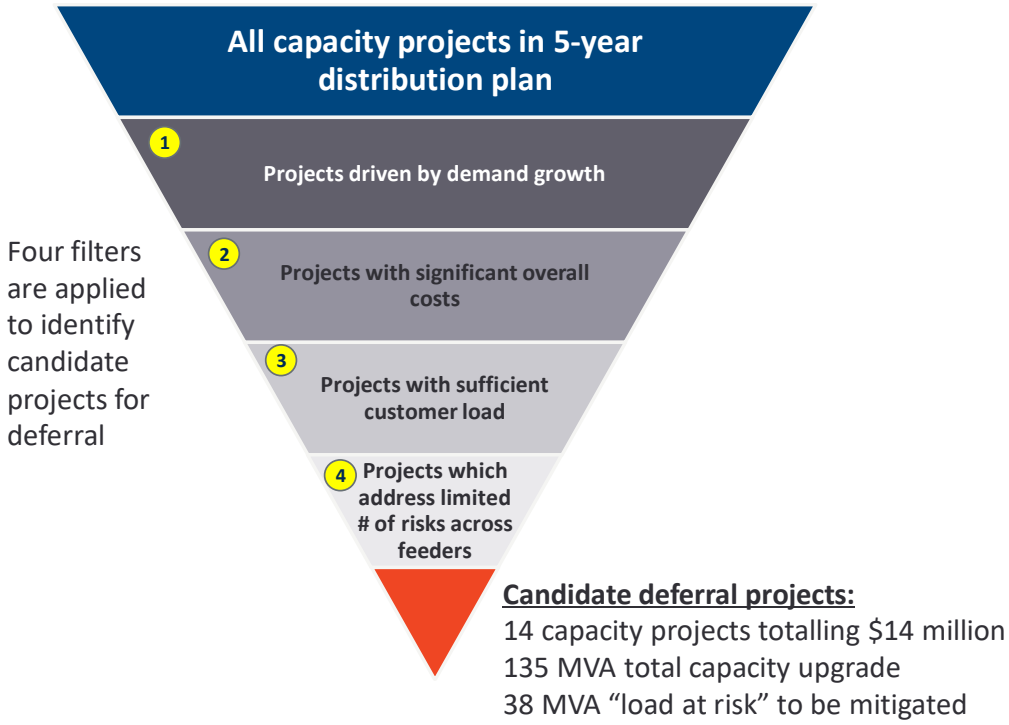
4. The project should not be needed to simultaneously address many risks across feeders. In some cases, distribution upgrades are needed to mitigate a number of different contingencies. There are significant operational challenges associated with using DR in a similar manner. Projects were screened out based on the number and severity of risks that they were intended to address.

After applying the above criteria, up to roughly 10% of the cost of NSP's 5-year plan remained as potentially deferrable through the use of DR. We have assumed linear growth in NSP's distribution capacity needs, meaning the geo-targeted distribution deferral opportunity increases by this amount every five years over the forecast horizon. Figure 17 summarizes the process for identifying geo-targeted distribution deferral opportunities.

[30] For simplicity, we assumed 1 MVA = 1 MW.

[31] "Load at risk" effectively represents the load reduction that would need to be achieved to defer the capacity upgrade.

Figure 18: Identification of Candidates for Geo-targeted Distribution Investment Deferral



Avoided energy costs

Load can be shifted from hours with higher energy costs to hours with lower energy costs, thus producing net energy cost savings across the system.[32] Hourly energy costs in this study are based on the 2018 MISO Transmission Expansion Plan (MTEP18) modeled day-ahead prices for the NSP hub. These modeled prices were used to capture evolving future system conditions that would not be reflected in historical prices. MTEP18 presents four "futures" that represent broadly different long-term views of MISO energy system, enabling the evaluation of the avoided energy value of DR under different market conditions.

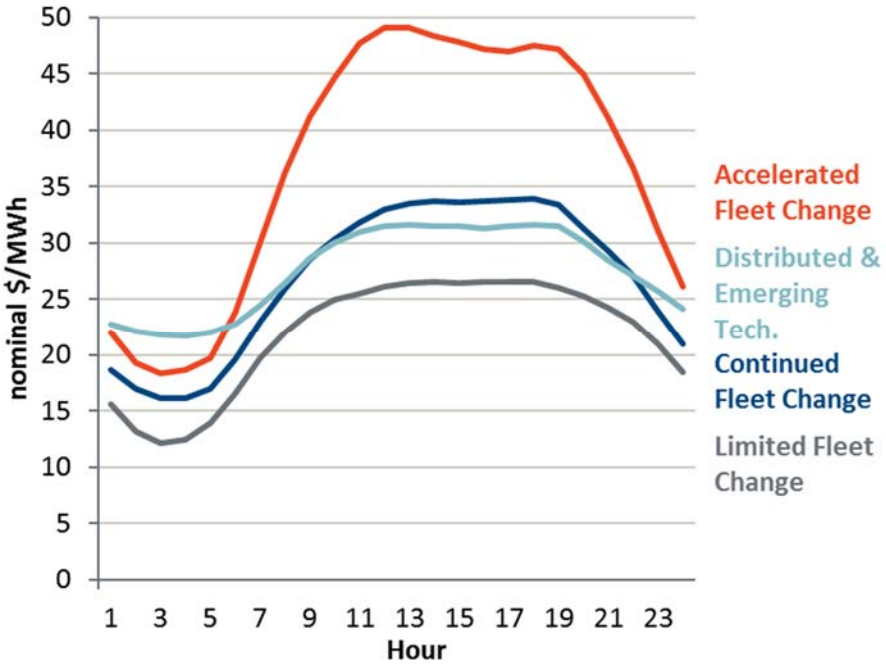
For the Base Case, we relied on prices from MTEP18's Continued Fleet Change (CFC) future. This future assumes a continuation of trends in the MISO market from the past decade: persistent low gas prices, limited demand growth, continued economic coal retirements, and gradual growth in renewables above state requirements.[33] Figure 19 below shows that 2022 energy prices under the

[32] Energy savings refer to reduced fuel and O&M costs. In this study, we do not model the impact that DR would have on MISO wholesale energy prices. This is sometimes referred to as the demand response induced price effect (DRIPE). It represents a benefit to consumers and an offsetting cost to producers, with no net change in costs across the system as a whole.

[33] See MISO, "MTEP 18 Futures – Summary of definitions, uncertainty variables, resource forecasts, siting process and siting results." for additional details on MTEP18 scenarios.

CFC future lie somewhere in the middle of the four MTEP scenarios (energy prices in other years follow the same relative pattern across scenarios).

Figure 19: Average Energy Price by Hour of Day in 2022 MTEP Scenarios for NSP Hub



For the High Sensitivity Case, we relied on prices from the Accelerated Fleet Change (AFC) future. The AFC case has twice the amount of renewable generation capacity additions as the CFC future. However, increased load growth, accelerated coal retirements, and higher gas prices lead to overall higher energy prices, particularly in daytime hours. For our analysis years (2023, 2025 and 2030), we relied on prices from the nearest MTEP modeling year (2022, 2027, and 2032, respectively) and adjusted them accordingly for inflation (assumed to be 2.2% per year).

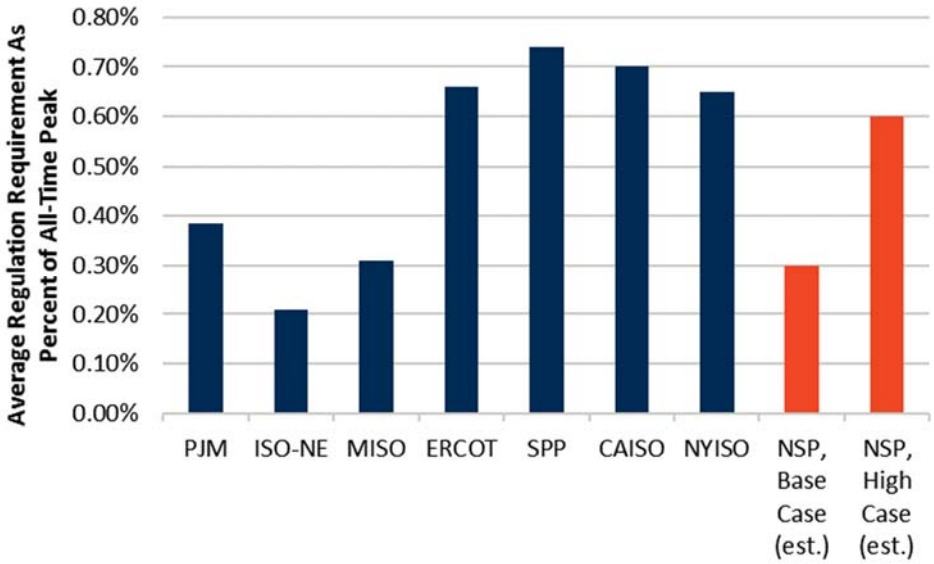
Ancillary services

The load of some end-uses can be increased or decreased in real time to mitigate system imbalances. The ability of qualifying DR programs to provide frequency regulation was modeled, as this is the highest-value ancillary service.

Frequency regulation is a high value resource with a very limited need. Across most markets, the need for frequency regulation capacity is less than 1% of the system peak. We assume that the frequency regulation needs in the NSP system across all analysis years are 25 MW (0.3% of annual peak) in the Base Case, and 50 MW in the High Sensitivity Case (0.6% of annual peak).[34] Figure 20 summarizes frequency regulation needs across various U.S. markets, demonstrating that the quantities of frequency regulation assumed in this study are consistent with experience elsewhere.

[34] Calculated assuming an annual peak of 8,335 MW after line losses.

Figure 20: Frequency Regulation Requirements Across Wholesale Markets



Sources and Notes: Values for wholesale markets extracted from PJM, "RTO/ISO Regulation Market Comparison", April 13, 2016. Orange bars for NSP assume that NSP's all-time peak is 8,335 MW at the customer level, based on three years of provided peak load data and assumed 8% line losses. Frequency regulation values for all markets are average levels as of 2016.

Because regulation prices were not available from the 2018 MTEP, we utilized 2017 hourly generation regulation prices for the MISO system adjusted for inflation.

Table 10 summarizes the potential value of each DR benefit. Values shown are the maximum achievable value. Operational constraints of the DR resources (e.g., limits on number of load curtailments per year) often result in realized benefits estimates that are lower than the values shown.

Table 10: Summary of Avoided Costs/Value Streams in 2023

Value Stream	Quantity of Need		Avoided Cost		Description
	Base Case	High Case	Base Case	High Case	
Avoided Generation Capacity	Unconstrained	Unconstrained	$63.0/kW-year	$81.5/kW-year	Base: Xcel's Brownfield CT costs minus estimated CT energy revenues from 2018 IRP, plus 2.4% reserve margin gross-up.
Avoided Transmission Capacity	Unconstrained	Unconstrained	$3.1/kW-year	$3.1/kW-year	72% of avoided transmission & distribution costs estimated under the discrete valuation approach in Xcel's 2017 T&D Avoided Cost Study.
Avoided Distribution Capacity	Unconstrained	Unconstrained	$8.0/kW-year	$8.0/kW-year	28% of avoided transmission & distribution costs estimated under the discrete valuation approach in Xcel's 2017 T&D Avoided Cost Study.
Geo-targeted Distribution Capacity	38 MW	38 MW	$25.8/kW-year	$25.8/kW-year	Total value of 14 projects identified as eligible for distribution capacity deferral by demand response.
Frequency Regulation	25 MW	50 MW	Avg: $12.4/MWh	Avg: $12.4/MWh	2017 MISO regulation prices. Assumes that NSP's share of regulation need is 25 MW in 2023 and 50 MW in 2030.
Avoided Energy	Unconstrained	Unconstrained	Avg: $27.5/MWh	Avg: $27.5/MWh	Hourly MISO MTEP18 modeled energy prices for NSP HUB. 2023 used prices from the CFC 2022 scenario, and 2030 used prices from the AFC 2032 scenario.
Top 10% Average			$50.5/MWh	$71.3/MWh	
Bottom 10% Average			$8.1/MWh	$8.6/MWh	

Notes: All values shown in nominal dollars. 2030 avoided costs are similar, rising at inflation.

Step 3: Develop 8,760 hourly profile of marginal costs

Each of the annual avoided cost estimates established in Step 2 is converted into a chronological profile of hourly costs for all 8,760 hours of the year. In each hour, these estimates are added together across all value streams to establish the total "stacked" value that is obtainable through a reduction in load in that hour (or, conversely, the total cost associated with an increase in load in that hour).

Capacity costs are allocated to hours of the year proportional to the likelihood that those hours will drive the need for new capacity. In other words, the greater the risk of a capacity shortage in a given hour, the larger the share the marginal capacity cost that is allocated to that hour.

Capacity costs are allocated across the top 100 load hours of the year. The allocation is roughly proportional to each hour's share of total load in the hours. This means more capacity value is allocated to the top load hour than the 100th load hour.

Different allocators are used to allocate generation, transmission, and distribution capacity costs. Generation and transmission capacity costs are allocated based on 2017 hourly MISO system gross load.[35] Distribution capacity costs are allocated based on hourly feeder load data provided by NSP. Both generic distribution capacity deferral and geo-targeted distribution capacity deferral value

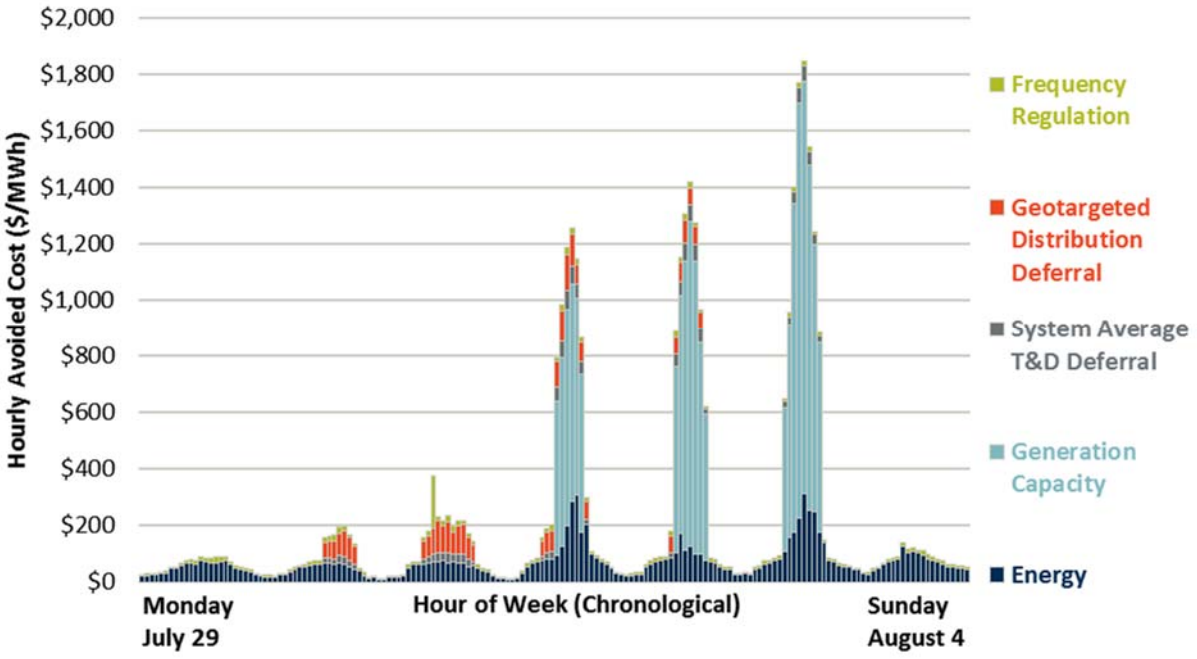
[35] Capacity value was allocated proportional to MISO gross load because NSP is required to use its MISO-coincident peak for resource adequacy planning decisions.

are allocated over a larger number of peak hours (roughly 330 hours, rather than 100 hours), representing that a single distribution project will address multiple feeders with load profiles that are only partially coincident.

A conceptually similar approach to quantifying capacity value is used in the California Energy Commission's time-dependent valuation (TDV) methodology for quantifying the value of energy efficiency, and also in the CPUC's demand response cost-effectiveness evaluation protocols. This hourly allocation-based approach effectively derates the value of distributed resources relative to the avoided cost of new peaking capacity by accounting for constraints that may exist on the operator's ability to predict and respond to resource adequacy needs. These constraints could result in DR utilization patterns that reflect a willingness to bypass some generation capacity value in order to provide distribution deferral value, for instance. The approach is effectively a theoretical construct intended to quantify long-term capacity value, rather than reflecting the way resource adequacy payments would be monetized by a DR operator in a wholesale market.

Figure 21 illustrates the "stacked" marginal costs associated with each value stream for a single week in the study period. The figure shows that certain hours present a significantly larger opportunity to reduce costs through load reduction – namely, those hours to which capacity costs are allocated.

Figure 21: Chronological Allocation of Marginal Costs (Illustration for Week of July 29)



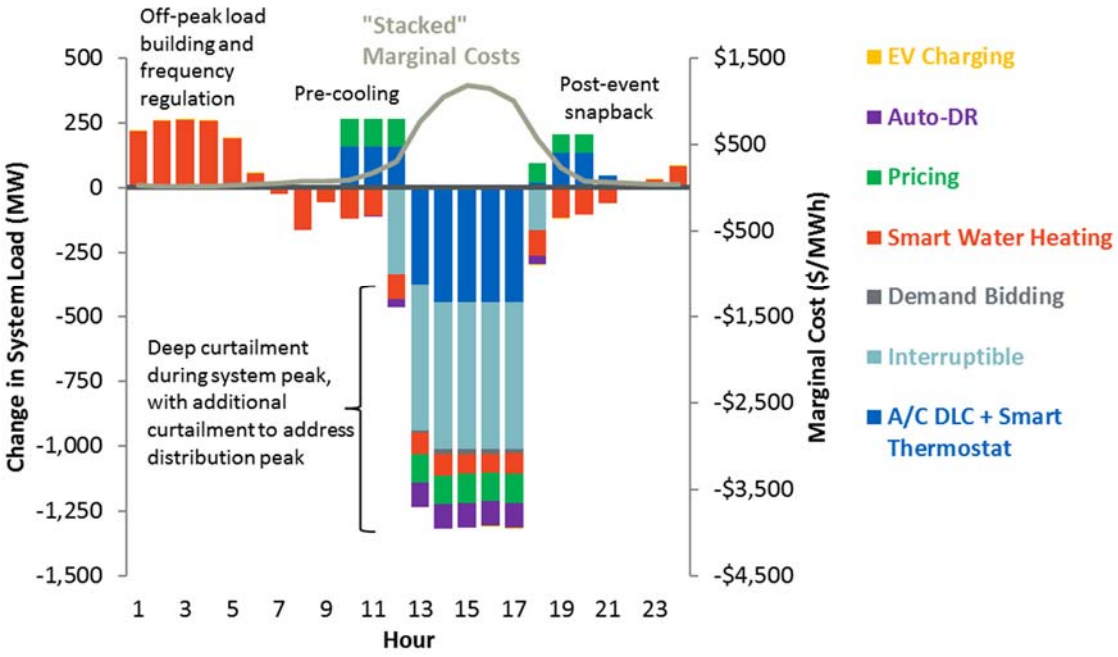
Notes: Marginal costs reflect avoided costs from the 2030 High Sensitivity Case.

Step 4: Optimally dispatch programs and calculate benefit-cost metrics

As discussed above, using DR to pursue one value stream may require forgoing opportunities to pursue other "competing" sources of value. While the value streams quantified in this study can be estimated individually, those estimates are not purely additive. A DR operator must choose how to operate the program in order to maximize its value. Accurately estimating the total value of DR programs requires accounting for tradeoffs across the value streams.

Load*Flex* employs an algorithm that "co-optimizes" the dispatch of a DR program across the hourly marginal cost series from Step 3, subject to the operational constraints defined in Step 1, such that overall system value produced by the program is maximized. In other words, the programs are operated to reduce load during hours when the total cost is highest and build load during hours when the total cost is lowest, without violating any of the established conditions around their use. Figure 22 illustrates how the dispatch of the High Sensitivity Case portfolio in this study compares to the hourly cost profile on those same days.

Figure 22: Illustrative Program Operations Relative to "Stacked" Marginal Costs



Through an iterative process, Load*Flex* determines when the need for a given value stream has been fully satisfied by DR in each hour, and excludes that value stream from that hour for incremental additions of DR. This ensures that DR is not over-supplying certain resources and being incorrectly credited for services that do not provide additional value to the system.

Step 5: Identify cost-effective incentive and participation levels

A unique feature of Load*Flex* is the ability to identify participation levels that are consistent with the incentive payments that are economically justified for each DR program. This ensures that each program's economic potential estimate is based on an incentive payment level that produces a benefit-cost ratio of 1.0. Without this functionality, the analysis would under-represent the potential for a given DR program, or could even exclude it from the analysis entirely based on inaccurate assumptions about uneconomic incentive payments levels.

As a starting point, participation estimates for each DR program are established to represent the maximum enrollment that is likely to be achieved when offered in NSP's service territory at a "typical" incentive payment level. The estimates are tailored to NSP's customer base using data on current program enrollment, as well as survey-based market research conducted directly with NSP's customers.[36] For DR programs not included in the market research study, we developed participation assumptions based on experience with similar programs in other jurisdictions and applied judgement to make the participation rates consistent with available evidence that is specific to NSP's customer base.

Table 11 summarizes these "base" participation rates for conventional DR programs. In all cases, participation is expressed as a percent of the eligible customer base. For instance, the population of customers eligible for the smart thermostat program is limited to those customers with central air-conditioning.

The 2017 values represent current participation levels. Values in future years reflect participation rates if the programs were offered as part of an expanded DR portfolio. This accounts for the fact that a single customer could not simultaneously participate in two different programs.

Residential air-conditioning load control participation assumptions reflect a transition from compressor switch-based direct load control program to a smart thermostat-based program. These programs are currently marketed by NSP as "Savers Switch" and "AC Rewards", respectively. Based on the aforementioned primary market research conducted in NSP's service territory, we estimate that a 66% participation rate among eligible customers is achievable at the medium incentive level for these programs collectively. In 2017, participation in air-conditioning load control programs reached 52% of eligible residential customers, mostly through the Savers Switch program. In the future, NSP will increase its marketing emphasis on the AC Rewards program as its primary air-conditioning load control program. Therefore, we assume that achievable incremental participation in residential air-conditioning load control transitions from an equal split between AC Rewards and Savers Switch in 2018 to a 75/25 split in favor of AC Rewards by

[36] Ahmad Faruqui, Ryan Hledik, and David Lineweber, "Demand Response Market Potential in Xcel Energy's Northern States Power Service Territory," April 2014.

2023. Additionally, NSP will focus on transitioning customers from Savers Switch to AC Rewards as compressor switches reach the end of their useful life. Based on information about the age of deployed switches and conversations with NSP, we assume that the number of switches replaced by smart thermostats grows from around 6,600/year in 2018 to 10,000/year in 2023 and onwards.

It is important to note that the participation rates shown are consistent with a participation incentive payment level that is representative of common offerings across the U.S. Participation rates are shown for all programs at these incentive levels, regardless of whether or not the programs are cost-effective at those incentive levels.[37] Later in this section of the appendix, we describe adjustments that are made to these "base" incentive levels to reflect enrollment that could be achieved at cost-effective incentive levels.

Table 11: Participation Assumptions for Conventional DR Programs

Participation as a percentage of eligible customers

Segment	Program	2017	2023	2030
Residential	A/C DLC - SFH	52%	50%	39%
Residential	Smart thermostat - SFH	0%	16%	24%
Residential	Smart thermostat - MDU	0%	35%	32%
Small C&I	A/C DLC	0%	30%	30%
Small C&I	Interruptible	0%	14%	12%
Small C&I	Demand Bidding	0%	2%	1%
Medium C&I	A/C DLC	73%	64%	64%
Medium C&I	Interruptible	3%	13%	11%
Medium C&I	Demand Bidding	0%	6%	5%
Large C&I	Interruptible	12%	44%	43%
Large C&I	Demand Bidding	0%	5%	4%

Notes:
Participation rates shown for programs at the portfolio level (i.e. accounts for program overlap). Lower participation rates for some programs in 2030 relative to 2023 result from customers switching to an opt-in CPP rate (for which participation estimates are shown separately). High Medium C&I participation in A/C DLC is relative to a small portion of the customer segment that is eligible for enrollment.

Table 12 illustrates the potential participation rates for each new DR program analyzed in the study. As noted above, these enrollment rates are consistent with "base" incentive payment levels and do not reflect enrollment associated with cost-effective payment levels. **Here, participation in each program is shown as if the program were offered in isolation.** In other words, it is the achievable participation level in the absence of other programs being offered. In our assessment of expanded DR portfolios that include multiple new DR programs, restrictions on participation in multiple programs are accounted for and the participation rates are derated accordingly.

[37] This is the basis for our estimate of "technical potential".

Table 12: Participation Assumptions for New DR Programs

Participation as a percentage of eligible customers

Segment	Program	2017	2023	2030
Residential	Behavioral DR (Opt-out)	0%	80%	80%
Residential	CPP (Opt-in)	0%	0%	20%
Residential	CPP (Opt-out)	0%	0%	80%
Residential	EV Managed Charging - Home	0%	20%	20%
Residential	EV Managed Charging - Work	0%	20%	20%
Residential	Smart water heating	0%	15%	50%
Residential	Timed water heating	0%	50%	50%
Residential	TOU - EV Charging (Opt-in)	0%	0%	20%
Residential	TOU (Opt-in)	1%	0%	16%
Residential	TOU (Opt-out)	0%	0%	80%

Medium C&I	TOU (Opt-out)	0%	0%	80%
Large C&I	Auto-DR (HVAC)	0%	5%	5%
Large C&I	Auto-DR (Light Luminaire)	0%	5%	5%
Large C&I	Auto-DR (Light Zonal)	0%	5%	5%
Large C&I	CPP (Opt-in)	0%	22%	22%
Large C&I	CPP (Opt-out)	0%	81%	81%
Large C&I	TOU (Opt-in)	100%	100%	100%

Notes:
Participation rates shown for programs when offered independently (i.e. rates do not account for program overlap).

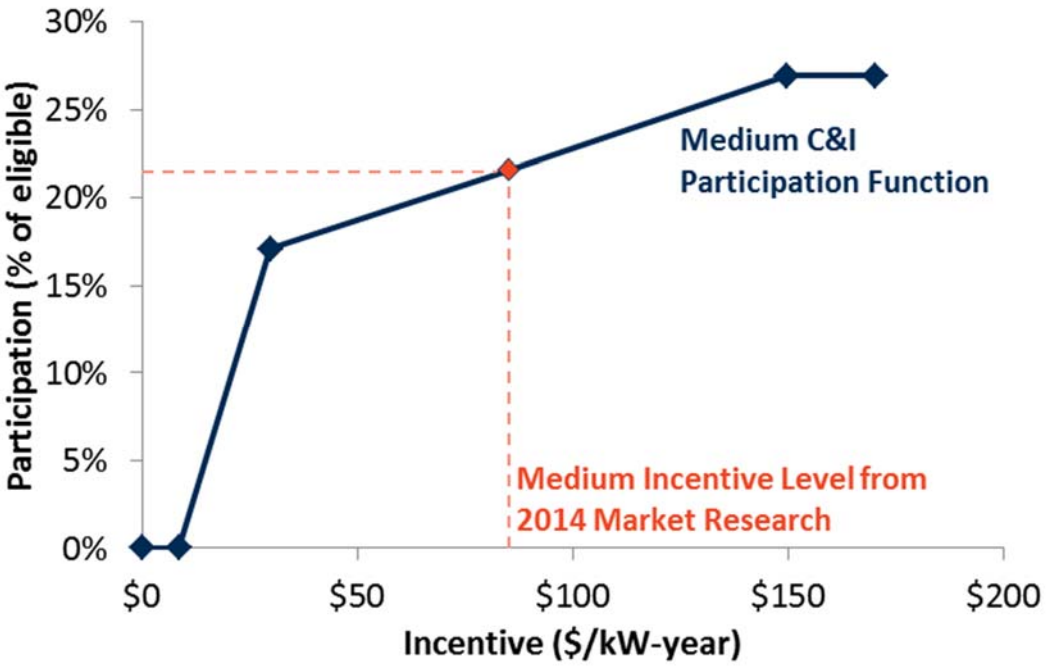
As discussed above, the cost-effectiveness screening process in many DR potential studies often treats programs as an all-or-nothing proposition. In other words, the studies commonly assume a base incentive level and then simply evaluate the cost-effectiveness of the programs relative to that incentive level. However, in reality, the incentives can be decreased or increased to accommodate lower or higher thresholds for cost effectiveness. For instance, in a region with lower avoided cost, a lower incentive payment could be offered, and vice versa. Program participation will vary according to these changes in the incentive payment level.

In Load*Flex* model, participation is expressed as a function of the assumed incentive level. The incentive level that produces a benefit-cost ratio of 1.0 is quantified, thus defining the maximum

potential cost-effective participation for the program.[38] The DR adoption function for each program is derived from the results of the aforementioned 2014 market research study, which tested customer willingness to participate in DR programs at various incentive levels.

An illustration of the participation function for the Medium C&I Interruptible program is provided in Figure 23. The figure expresses participation in the program (vertical axis) as a function of the customer incentive payment level (horizontal axis). At an incentive level of around $85/kW-yr, slightly more than 20% of eligible customers would participate in the program. If the economics of the program could only justify an incentive payment less than this (e.g., due to low avoided capacity costs), participation would decrease according to the blue line in the chart, and vice versa. Below an incentive payment level of around $25/kW-yr, customer willingness to enroll in the program quickly drops off.

Figure 23: Medium C&I Interruptible Tariff Adoption Function



Step 6: Estimate cost-effective DR potential

After the cost-effective potential of each individual DR program is estimated, the programs are combined into a portfolio. Constructing the portfolio is not as simple as adding up the potential estimates of each individual program. In some cases, two programs may be targeting the same end-use (e.g., timed water heating and smart water heating), so their impacts are not additive.

[38] In some cases, the non-incentive costs (e.g., equipment costs) outweigh the benefits, in which case the program does not pass the cost-effectiveness screen.

In instances where two cost-effective programs target the exact same end-use, we have assumed that the portfolio would only include the program that produces the larger impact by the end of the study horizon. In the water heating example, this means that the smart water heating program was included and the timed water heating program was not.

In other cases, two "competing" programs would likely be offered simultaneously to customers as mutually exclusive options. For instance, it is possible that C&I customers would only be allowed to enroll in either an interruptible tariff program or a CPP rate. Simultaneous enrollment in both could result in customer being compensated twice for the same load reduction – once through the incentive payment in the interruptible tariff, and a second time through avoiding the higher peak price of the CPP rate. In these cases, we relied on the results of the aforementioned 2014 market research study, which used surveys to determine relative customer preferences for these options when offered simultaneously. Participation rates were reduced in the portfolio to account for this overlap.

In cases where two programs would be offered simultaneously to the same customer segment, but would target entirely different end-uses (e.g., a smart thermostat program and an EV charging load control program), no adjustments to the participation rates were deemed necessary.

Appendix B: NSP's Proposed Portfolio

At a stakeholder meeting on August 8, 2018, NSP presented a draft portfolio of proposed DR programs. The DR portfolio that NSP is considering consists of the programs and deployment years summarized in Table 13.

Table 13: NSP's Draft Portfolio of DR Programs

Program	First Year of Rollout
Saver's Switch	Existing
A/C Rewards	Existing
EV home charging control	2020
Med/large C&I Auto-DR	2021
Med/large C&I interruptible tariff (program expansion)	2021
Med/large C&I Opt-in CPP	2022
Residential smart water heating	2023
Residential behavioral DR	2023
Residential opt-out TOU	2024

The potential for this portfolio was quantified under the Base and High Sensitivity cases for years 2023 and 2030. Results are summarized in Table 14. In the table, the values in the row labeled "All Proposed Programs" indicate the incremental technical potential in each of the programs that have been proposed by NSP. The values in the row "Cost-Effective Proposed programs" indicate the amount of incremental DR in the proposed programs that can be achieved at cost-effective incentive payment levels. In both cases, DR potential is shown at the portfolio level, accounting for overlap in participation when multiple programs are offered simultaneously.

Table 14: Incremental Potential in NSP's Draft Portfolio of DR Programs (MW)

	Base Case		High Sensitivity Case	
	2023	2030	2023	2030
All Proposed Programs	642	907	658	927
Cost-Effective Proposed Programs	262	461	411	677

Note: Values shown are incremental to the existing 850 MW portfolio.

Appendix C: Base Case with Alternative Capacity Costs

For its 2019 IRP, NSP has developed cost assumptions for new CT capacity at brownfield and greenfield sites. Our Base Case assumptions rely on brownfield CT costs as the avoided generation cost estimate, as this is the lowest cost option available to NSP for future peaking generation development. To test the sensitivity of our findings to that assumption, we modeled an alternative case in which the avoided capacity cost in the Base Case is based on a greenfield CT rather than a brownfield CT.[39] Other Base Case assumptions remained unchanged.

The greenfield CT capacity cost is higher than the brownfield CT cost, which increases the benefits of DR programs due to higher avoided generation costs. Relative to the Base Case, the cost-effective incremental potential in the DR portfolio increases by 73 MW in 2023 and by 119 MW in 2030. Nearly all of this increase in potential is attributable to a further expansion of participation in programs that were already cost-effective in the Base Case. The additional potential is mostly in the smart thermostat program, increases from 112 MW to 148 MW in 2023 and from 169 MW to 220 MW in 2030. Other programs that were economic in the Base Case (residential smart water heating, additional C&I interruptible, and demand bidding) also have small increases in cost-effective potential.

The only program that was initially uneconomic under Base assumptions but becomes economic under the greenfield CT capacity cost assumption is HVAC-based Auto-DR: 3 MW of Large C&I Auto-DR becomes cost-effective in 2023, growing to 6 MW in 2030 (in addition to 32 MW of Medium C&I Auto-DR). Together, these programs account for 4% of additional potential in 2023, but over 30% of additional potential in 2030.

Table 15 compares the portfolio-level incremental DR potential for the Base Case with brownfield CT costs to the alternative case with greenfield CT costs. Annual program-level potential estimates are provided in Appendix D.

[39] Table 9 of this report summarizes the greenfield, brownfield and AEO 2018 CT costs used in this analysis.

Table 15: Incremental Cost-Effective Potential in Portfolio of DR Programs with Alternative CT Costs (MW)

	2023	2030
Base Case (Brownfield CT Cost)	306	468
Alternative Case (Greenfield CT Cost)	378	587
Difference (Alternative - Base)	73	119

Note: Values shown are incremental to the existing 850 MW portfolio.

Appendix D: Annual Results Summary

Notes:
Figure shows incremental load reduction available when DR programs are offered in isolation.
Measure-level results do not account for cost-effectiveness or overlap when offered simultaneously as part of a portfolio.
No incremental potential is shown for residential air-conditioning load control, because NSP is transitioning it to the smart thermostat program.

December 2017

THE Brattle GROUP

Copyright © 2017 The Brattle Group, Inc.

Introduction

In 2014, Brattle conducted a bottom-up assessment of demand response (DR) potential in Minnesota, but did not evaluate DR cost-effectiveness

- The study identified around 400 MW of traditional DR "technical potential" in the sense that it did not account for the cost-effectiveness of the DR measures
- These estimates of DR potential were not estimates of economic potential; they were inputs to the resource planning modeling process

Subsequently, a range of views on cost-effective DR potential emerged in Minnesota

- NSP has estimated between 71 and 130 MW of incremental economic potential
- The PUC has established a requirement of 400 MW of additional DR capability by 2023 and consideration of 1,000 MW of new DR by 2025

The purpose of this presentation is to revisit the 2014 Potential Study and provide Brattle's assessment of the amount of cost-effective DR available from that study

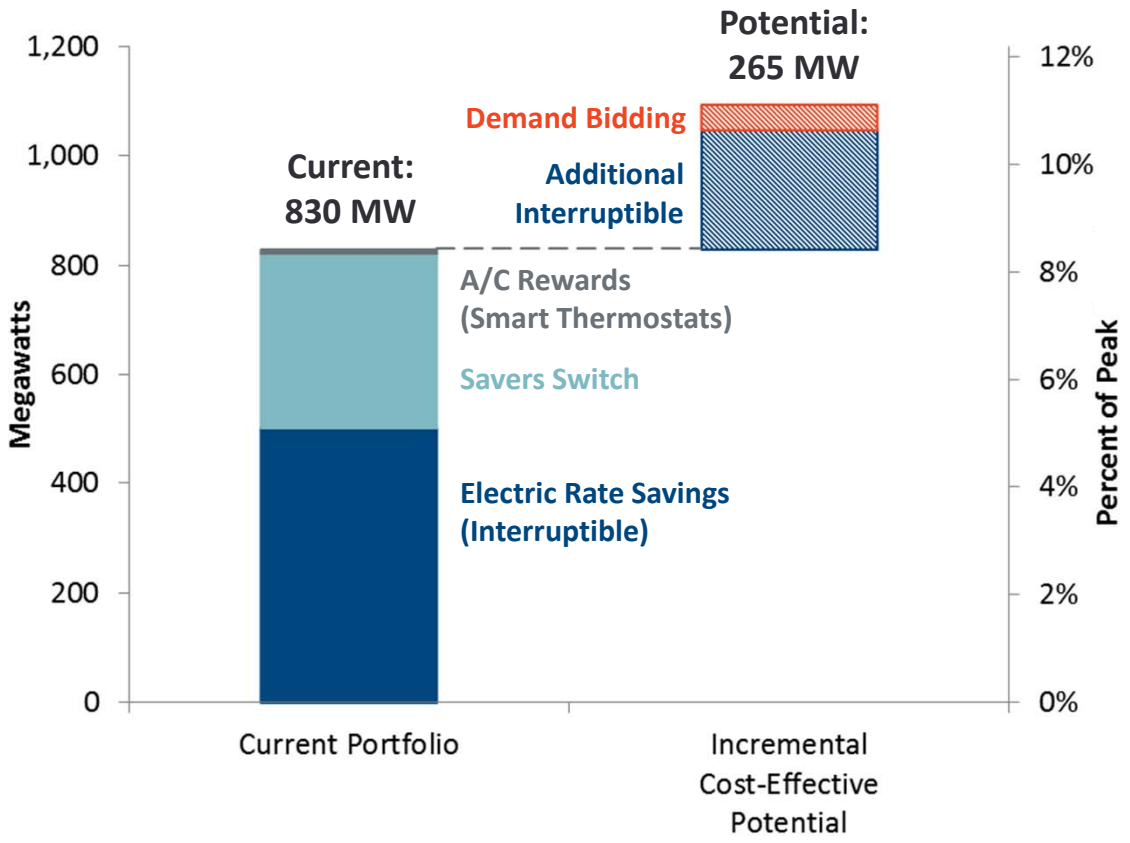
Note: 71 MW economic potential estimate identified by Staff in an October 2016 briefing paper, based on review of NSP IRP modeling data. 130 MW based on preliminary cost-effectiveness analysis conducted by NSP in 2015 (prior further detailed IRP modeling), as filed in Appendix N to the Resource Plan.

Key Findings

Comments

- NSP's current DR portfolio is one of the largest in the U.S.
- The market for traditional cost-effective DR in MN may be approaching saturation
- We identified 260 MW of incremental cost-effective DR potential among the options considered in the 2014 Study
- This estimate is subject to uncertainty; through probabilistic simulation, we estimate that there is a 75% chance the potential is under 300 MW
- There may be additional value in around-the-clock load flexibility (not quantified in this study)

Existing DR Capability and Cost-Effective Potential



Notes: Potential shown for 2023. Projected 2023 peak load of 9,848 MW was used as basis for estimating % of peak impact. All impacts shown at the generator-level (grossed up for losses). A/C Rewards was launched as a pilot program in August 2017.

Key findings (cont'd)

In spite of the limited amount of traditional incremental cost-effective DR identified in this study, there may be more value in alternative forms of demand flexibility

Emerging opportunities for "demand flexibility" include

- Renewables integration: Providing a suite of DR programs that mimic energy, capacity, and a range of ancillary services in response to rapidly changing system conditions
- Distribution benefits: Geographically-targeted programs designed to defer the need for expensive upgrades in capacity-constrained locations on the system

Accordingly, the definition of demand response should be expanded and assessed in the next IRP

- Emerging DR programs include thermal storage (e.g., grid-integrated water heaters), bring-your-own-thermostat programs, behavioral DR, electric vehicle charging control, and AMI-enabled time-varying pricing
- The definition could also be expanded to include options such as distributed battery storage, combined heat-and-power (CHP), and some types of energy efficiency

Organization of the presentation

1. **A national perspective on NSP's DR portfolio**
2. **Best practices for quantifying DR cost-effectiveness**
3. **Our assessment of NSP's cost-effective DR potential**
4. **Moving forward with DR in Minnesota—initial thoughts**

A National Perspective on NSP's DR portfolio

We benchmarked NSP's DR portfolio against other utilities in the U.S.

For context, it is helpful to first understand how NSP's portfolio compares to those of other utilities

The benchmarking analysis relied largely on DR program data from two sources: the FERC and the EIA

- From 2006 to 2012, FERC conducted a bi-annual survey of utility DR programs, including significant detail on program type, enrollment, capability, etc.
- The EIA annually collects basic aggregate data on DR enrollment and capability by major customer class; the most recent data is from 2015
- While the FERC data is older, it appears to contain fewer reporting errors and is therefore the primary data source we relied on in our analysis
- We do not anticipate that changes in utility DR programs since 2012 would materially change the broad findings of the benchmarking analysis

See Appendix A for additional detail on benchmarking analysis

NSP currently has 830 MW of DR capability

Comments

Savers Switch:

Air-conditioning direct load control (DLC) program, mostly targeting residential and small C&I customers

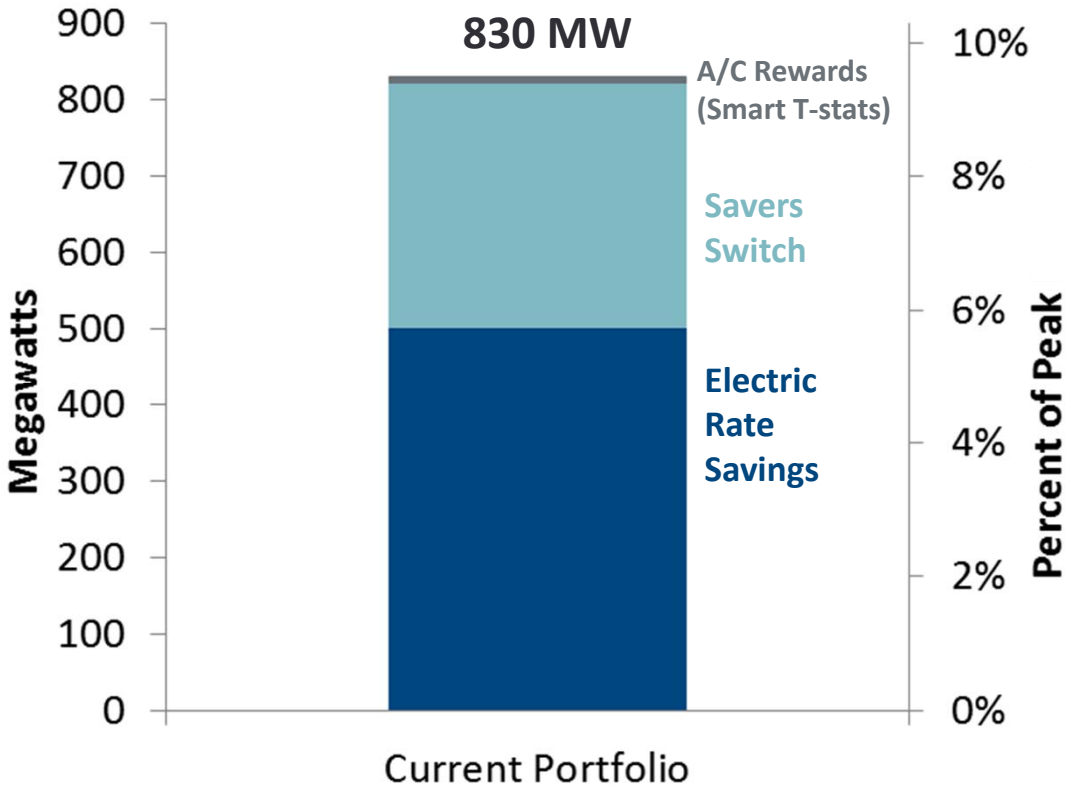
A/C Rewards:

Direct load control for customer-owned smart thermostats (residential)

Electric Rate Savings:

Interruptible tariff, targeting medium to large C&I customers

NSP DR Capability (2017)



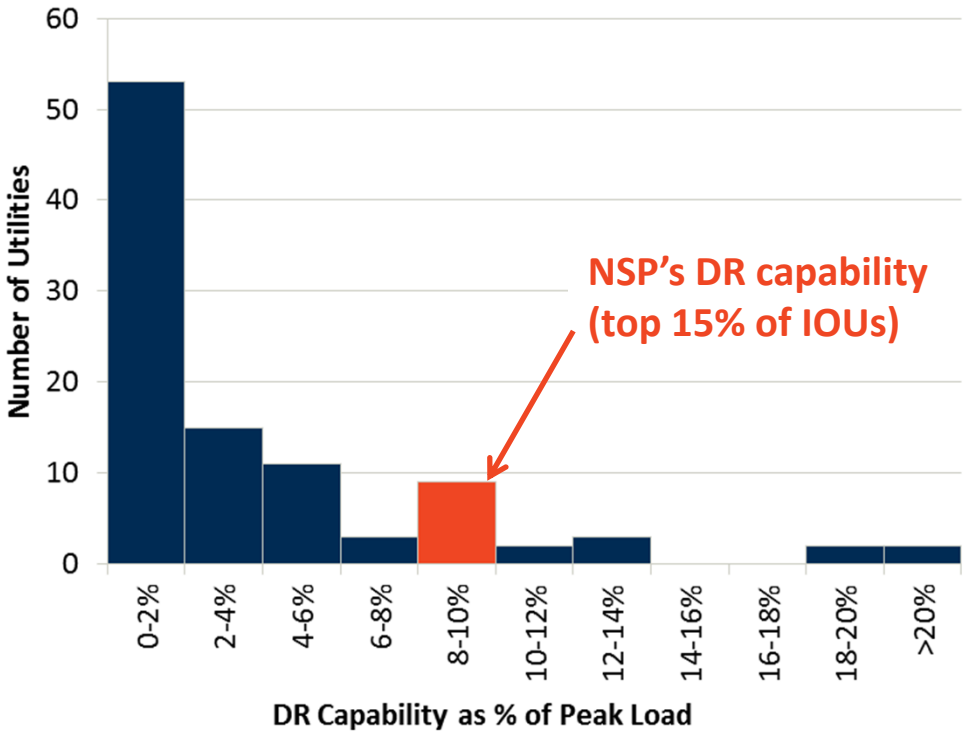
Notes: Percent of peak impact shown relative to actual 2016 peak load of 8,774 MW. All impacts shown at the generator-level (grossed up for losses). A/C Rewards was launched as a pilot program in August 2017. See appendix for further description of programs.

NSP's DR capability is in the top 15% of U.S. IOUs

Comments

- NSP's residential A/C load control program is the **2nd** most highly subscribed DR program in the country
- Around half of all eligible households are participating in NSP's Saver's Switch program
- In terms of absolute megawatts, NSP's portfolio is the **8th** largest program in the country; as a % of peak demand, it is ranked **11th**

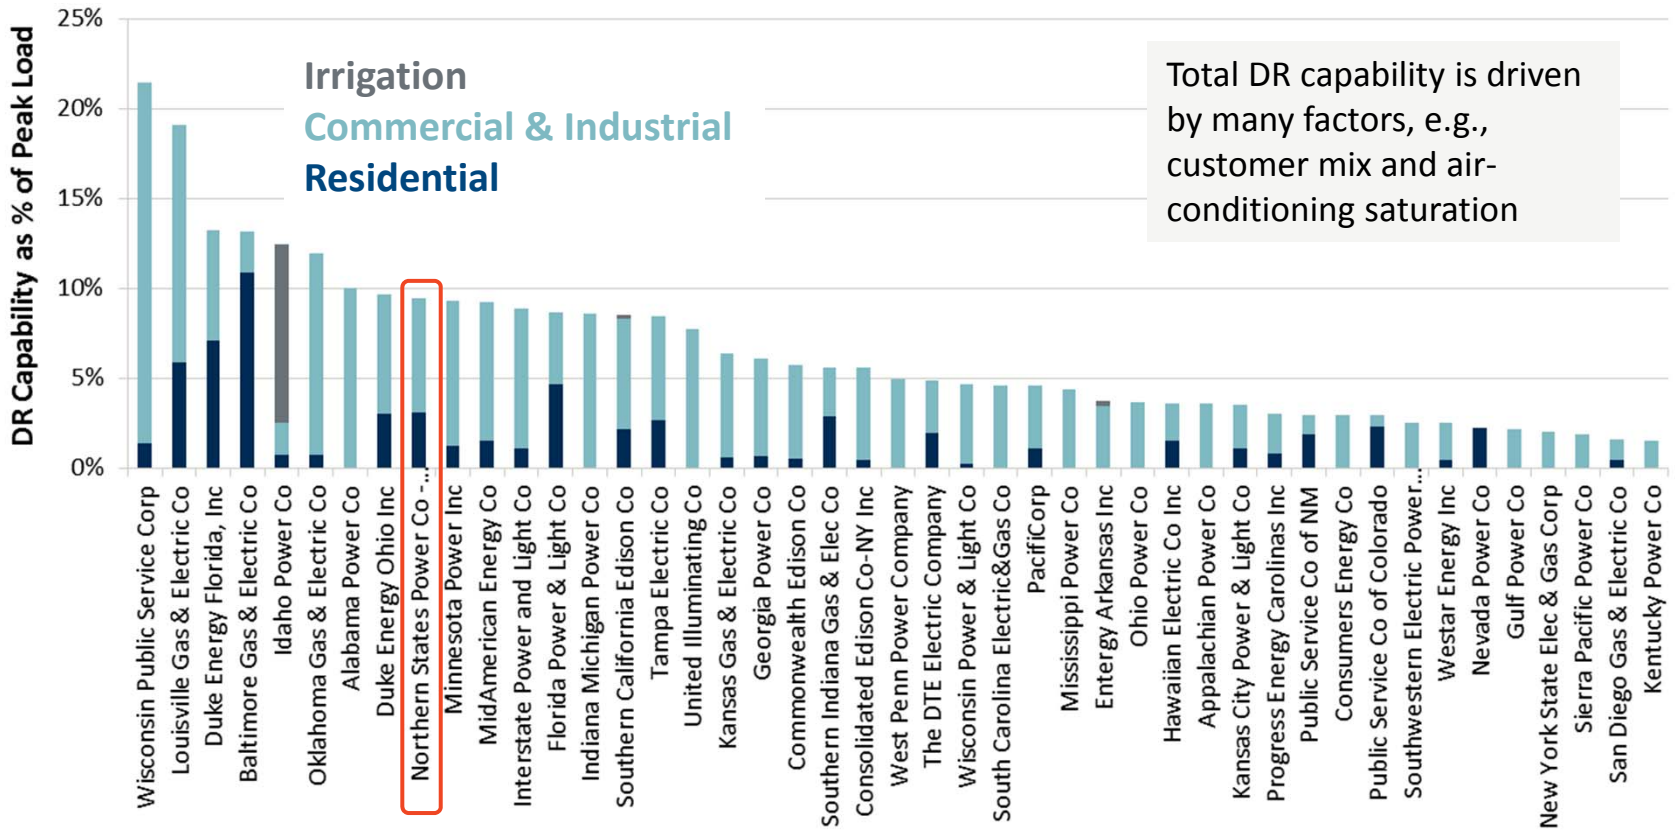
Distribution of DR Capability Among All U.S. IOUs



Sources and Notes: FERC, *2012 Assessment of Demand Response and Advanced Metering* and EIA 861 peak load data. Sample of 100 U.S. IOUs. Excludes IOUs that did not participate in the FERC survey, and excludes peak reduction capability from time-of-use programs because these loads are not controllable. NSP's capability calculated as current portfolio divided by 2016 peak load.

NSP ranks near the top of the largest IOU DR portfolios in terms of % of peak load

DR Capability of 45 IOUs with Largest Programs (as % of Peak Demand)



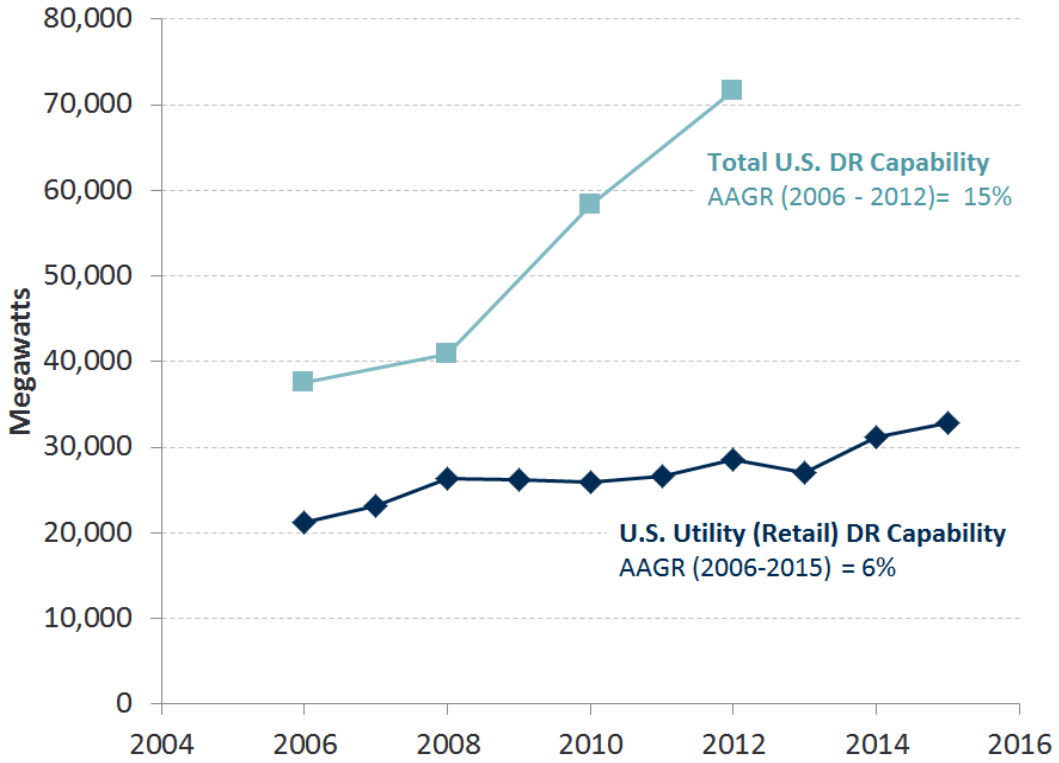
Sources and Notes: FERC, *2012 Assessment of Demand Response and Advanced Metering* and EIA 861 peak load data. Sample of 100 U.S. IOUs. Excludes IOUs that did not participate in the FERC survey, and excludes peak reduction capability from time-of-use programs because these loads are not controllable. NSP's capability calculated as current portfolio divided by 2016 peak load.

National DR growth has been driven by ISO/RTO programs – much more than by utility programs

Comments

- There is sometimes a misperception that utility DR programs were the primary drivers of DR growth over the past decade
- While U.S. DR capability grew at an annual rate of **15%** between 2006 and 2012, most of this growth was driven by programs operated by ISOs and RTOs
- PJM accounted for roughly half of the total ISO/RTO growth, in part due to significant efforts to integrate DR into its capacity market, which offered significant payments for demand reductions
- Utility DR programs only grew at an annual rate of **6%** during that time

Distribution of DR Capability Among all U.S. IOUs



Sources and Notes: Total U.S. DR Capability reflects data reported in 2006–2012 FERC surveys, which include DR capability provided by aggregators , power marketers, and state and federal energy authorities. U.S. Utility (Retail) DR Capability reflects data reported in 2006–2015 EIA-861 data.

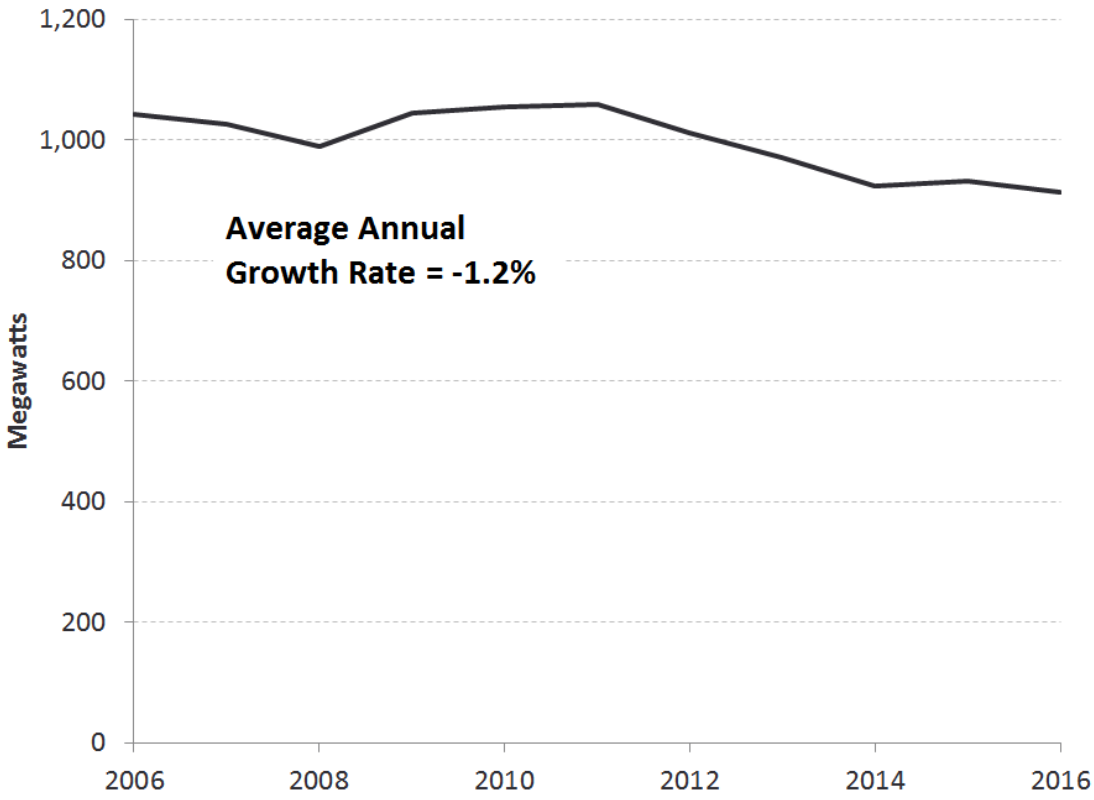
Relative to modest national growth in utility DR over the past decade, NSP's DR capability has dipped

Comments

A few explanations:

- EPA constraints on the use of backup generation as DR, imposed in 2013
- Increased utilization of the interruptible tariff program in 2016, leading to some drop-outs
- Allowing DR participants to lower their contractually committed load reduction level in anticipation of more frequent program use
- Possibly approaching market saturation due to high enrollment rates (relative to other U.S. utilities)

Historical NSP DR Capability



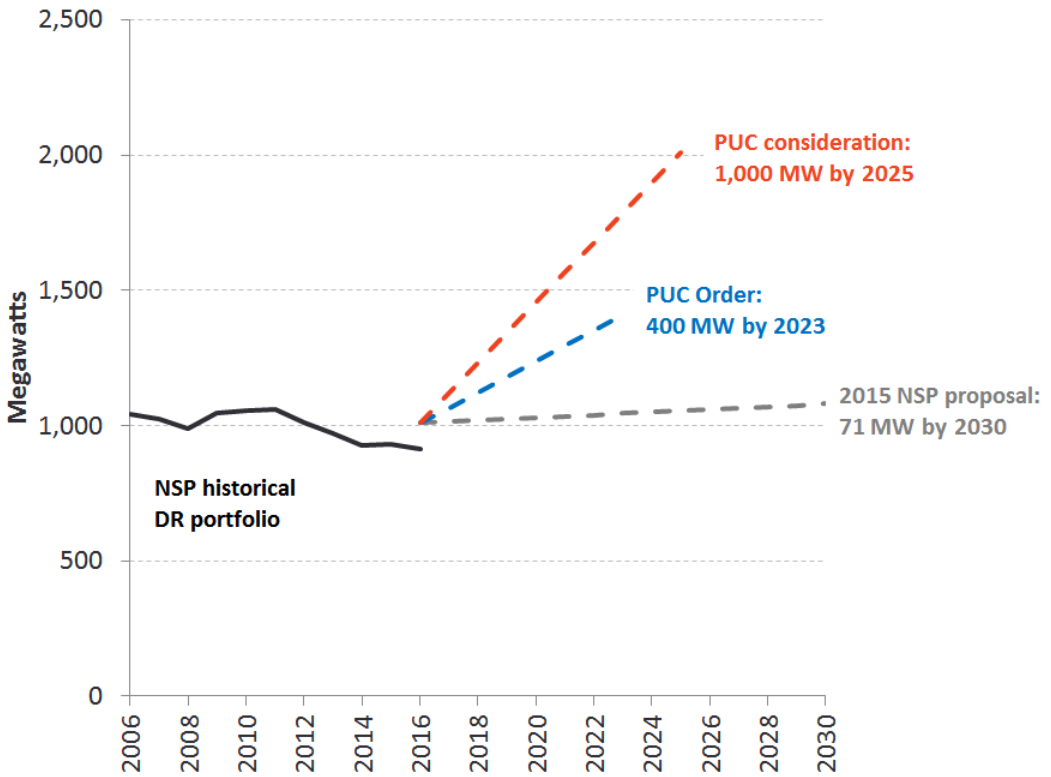
Sources and Notes: Data provided by NSP. Values shown are for entire NSP service territory.

To what extent can NSP's DR portfolio cost-effectively grow beyond recent levels?

Comments

- NSP proposed to reverse the recent historical decline with 71 MW of DR growth
- The PUC has ordered NSP to pursue 400 MW of additional DR
- The PUC's interest in 1,000 MW of new DR would significantly exceed historical observed growth rates among U.S. utilities
- **In the remainder of this presentation, we explore where NSP's cost-effective DR potential falls on this spectrum**

DR Proposals Relative to Historical Growth



Sources and Notes: Data provided by NSP. Projections of growth were established by the PUC and NSP relative to the size of the 2014 DR portfolio; therefore, they do not align with 2016 reported values.

Best Practices for Quantifying the Cost-Effectiveness of DR

There are two established options for determining the cost-effectiveness of DR

1. Incorporate DR options into the resource planning model

- Dynamically accounts for the advantages and disadvantages of DR relative to supply-side options
- However, it is difficult to implement comprehensively due to modeling and computational limitations

2. Conduct a detailed cost-effectiveness screening

- Performed outside of the IRP model
- Commonly used in regulatory proceedings to evaluate DR and EE cost-effectiveness (i.e., the Total Resource Cost test)
- Has the advantage of transparency, while still relying on the same cost and operational assumptions used in the IRP model
- Allows for a broader range of sensitivity cases around uncertain variables

We rely on the screening-based approach

The value of DR is assessed based on its ability to avoid the need for new peaking generation

The DR programs analyzed in the 2014 Potential Study are most appropriately considered substitutes for new combustion turbine (CT) capacity

CTs are "peaking" units with relatively high variable costs; as a result, they typically only run up to **a few hundred hours of the year**, when electricity demand is very high and/or there are system reliability concerns

Similarly, use of DR programs in the U.S. is typically limited to **<100 hours per year** – this constraint is either written into the tariff or is otherwise a practical consideration to avoid customer fatigue and program drop-outs

In contrast, new intermediate or baseload capacity (e.g., gas-fired combined cycle) has a higher capital cost and lower variable cost than a CT, and therefore will run **thousands of hours per year**

The DR programs considered in the 2014 Potential Study cannot feasibly avoid the need for new intermediate or baseload capacity, because they cannot be called during a sufficient number of hours of the year; energy efficiency is a more comparable demand-side alternative to these resource types since it is a permanent load reduction that applies to a much broader range of hours

Note: For more data on the number of interruptions per year in a typical U.S. DR program, see SEPA, "2017 Utility Demand Response Market Snapshot," October 2017.

Comparing traditional DR to a new CT

Even though traditional DR is most comparable to a CT, there are operational differences between these resources that must be taken into account

	Demand Response	New Combustion Turbine
Total hours of availability	Roughly 100 hrs/yr	Roughly 8,200 hrs/yr (accounting for planned and unexpected maintenance)
Seasonal availability	A/C: Summer only; Other programs: year-round	Year-round
Daily window of availability	A/C: roughly 2 to 7 pm; Other programs: business hours	Any hour of day
Other considerations	Must try to limit consecutive interruptions	None
Variable cost	$0/MWh	$40/MWh
Fixed cost	$30-250/kW-yr	$50-70/kW-yr

CTs can run any hour of the year (subject to outages), whereas the timing of DR use is constrained

DR costs are largely fixed incentive payments and/or up-front investment in technology; there is not usually a cost to call a DR event

DR fixed costs include incentives, equipment, marketing & administration. CT fixed cost based on values reported in NSP's IRP. CT variable cost assumes $3/MMBtu delivered gas price, and CT heat rate of 9.75 MMBtu/MWh and VOM of $10/MWh, consistent with an 'advanced CT' in EIA's *Updated Capital Cost Estimates for Utility Scale Generating Plants* (2013).

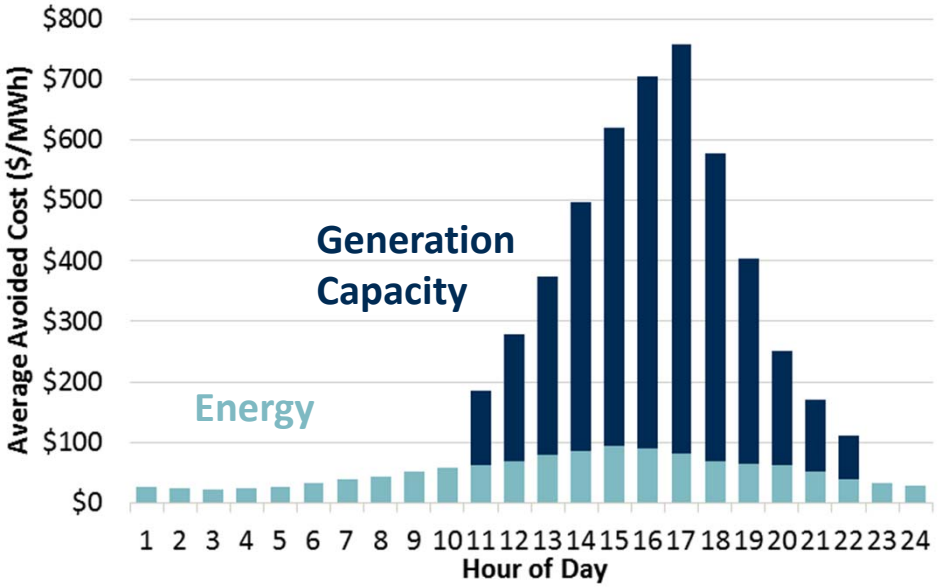
In addition to operational differences, considerations such as the dependability of the resource may also factor into the decision. See Appendix B for additional discussion of DR operational constraints

We account for the operational constraints of DR in our cost-effectiveness analysis

Comments

- Capacity costs are allocated to hours of the year proportional to the risk of capacity shortages in those hours
- In the base scenario, capacity costs are allocated to the top 100 system load hours of the year (this assumption is tested through sensitivity analysis)
- The allocation is roughly proportional to each load hour's share of total load in the hours (i.e., more capacity cost is allocated to the top load hour than the 100th)
- A similar approach has been used in California's DR cost-effectiveness protocols, and in the state's time-dependent valuation (TDV) metric for quantifying the value of energy efficiency
- The hourly allocation of capacity costs is added to 2013 hourly MISO energy market prices for NSP's service territory

Allocation of Marginal Costs: 2023 Average over Days With Capacity Value



Notes: On days without peak capacity constraints, there is no allocation of capacity value. Avoided costs shown for 2023 in nominal dollars. 2013 energy prices escalated to 2023 dollars assuming 2.2% inflation.

Avoided T&D capacity costs are also included in the analysis

Avoided T&D capacity costs are only sometimes included in assessments of DR cost-effectiveness

- Depends on DR program objectives and the physical characteristics of the utility system
- Requires higher frequency of interruptions due to lack of coincidence between transmission and distribution system peaks

Nationally, T&D investment needs are increasingly being driven by factors other than peak demand growth, limiting the T&D value of peak demand reductions. Factors commonly driving T&D investment include

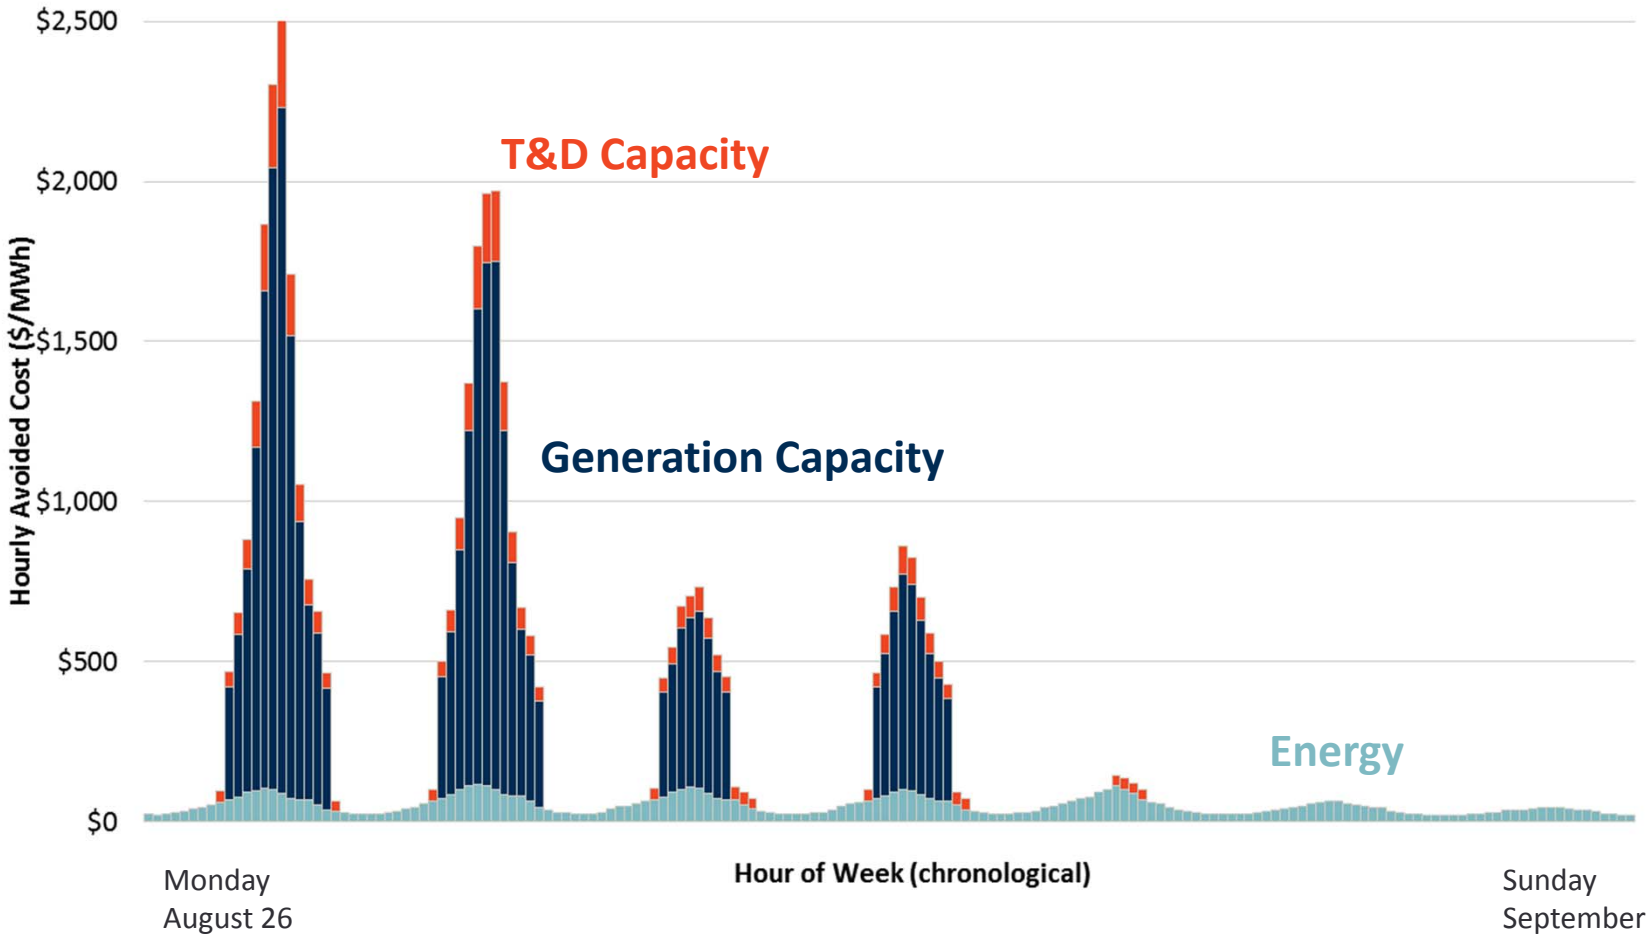
- Replacement of aging equipment
- General reliability improvements that are unrelated to peak demand
- Expansion to accommodate renewable generation

In Minnesota, there is no established approach to the treatment of T&D costs in DR cost-effectiveness analysis

- Docket No. E999/CIP-16-541 established a marginal (i.e., avoidable) T&D capacity cost of approximately $11/kW-year for NSP's energy efficiency programs
- We have adopted this as the base case marginal T&D capacity cost for DR
- In our analysis, the $11/kW-year is allocated across hours of the year in a manner similar to generation capacity, but spread over twice as many hours to account for the lack of coincidence between the overall system peak and the T&D peaks

DR is "dispatched" against the resulting hourly generation cost profile (energy + capacity + T&D)

Chronological Allocation of Marginal Costs (Illustration for Week of August 26)



Our methodology allows for robust representation of uncertainty in key variables

We first assess cost-effectiveness through "deterministic analysis"

- This is the standard industry approach
- The approach produces a point-estimate of cost-effective DR potential
- It is based on "most likely" (i.e., Base Case) values for each key variable
- However, it does not account for uncertainty in the key assumptions

We then assess cost-effectiveness through "probabilistic analysis"

- This is also known as "Monte Carlo analysis"
- It accounts for the range of uncertainty in the key variables
- A probability distribution is assigned to each uncertain variable
- Each probability distribution has an associated minimum, maximum, and most likely value based on historical data, experience from other jurisdictions, and/or our expert judgment
- A value is randomly drawn from each distribution and cost-effectiveness is estimated using those randomly selected values
- This process is repeated 2,000 times to establish a distribution of possible outcomes around the amount of cost-effective DR potential

Other key assumptions in the analysis

Avoided generation capacity cost

- $57/kW-year: This is the 2023 CT cost from NSP's IRP ($69/kW-year) adjusted downward to account for energy profit margins that the unit would earn ($12/kW-yr)
- Lower-bound of probabilistic analysis = $8/kW-yr, based on recent MISO capacity prices
- Upper-bound = $79/kW-year, based on MISO Net Cost of New Entry assumptions for CTs

Avoided T&D cost

- Base = $11/kW-yr, from 2017 EE Avoided T&D Cost Study (Discrete Method)
- Lower-bound = $0
- Upper-bound = $42/kW-year, the 2023 value from Xcel's 2016 filing for the 2017-19 Conservation Improvement Program filing (Docket No. 16-115)
- Note: The upper-bound reflects a value observed in some other jurisdictions. T&D costs are highly system-specific, therefore it does not directly reflect NSP's costs. The value is simply included to establish an upper-bound on the range of costs that may generally be avoided through system-wide reductions in demand through DR programs.

Avoided energy costs

- Based on 2013 MISO hourly day-ahead LMPs for Minnesota hub

DR program operational constraints

- Air-conditioning DLC: 15 interruptions per summer, 2 pm to 7 pm
- Other programs: 80-100 hours of interruption, minimum 1 hour duration per interruption (note: assumed interruptions are significantly more frequent than current operation of the programs)

Relevant programs

- The analysis is limited to non-pricing programs (DLC, interruptible tariffs, demand bidding)
- These are the programs that were included in the "DR supply curves" created in the 2014 study

Our Assessment of NSP's Cost-Effective DR Potential

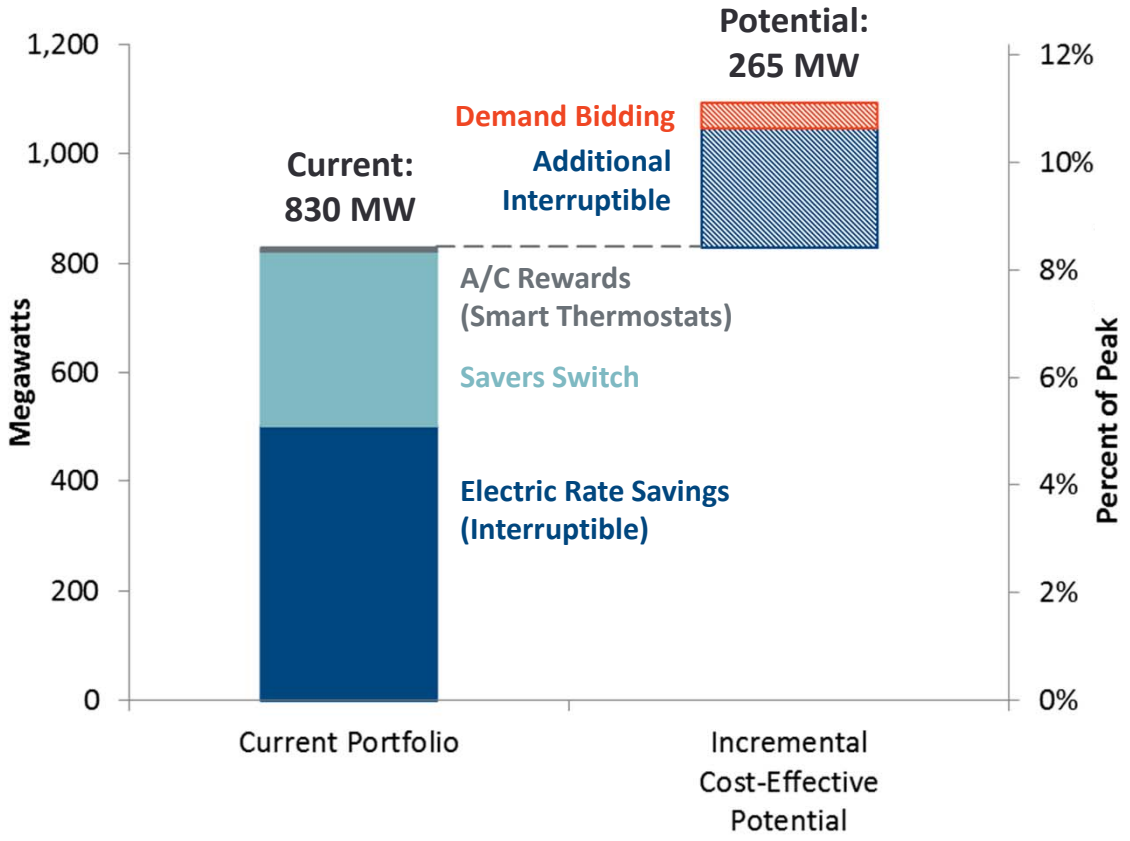
Results of Deterministic Analysis

In the Base Case, we estimate 265 MW of cost-effective potential for new DR programs

Comments

- Incremental potential resides primarily in an expansion of the interruptible tariff offering for medium C&I customers
- There is modest incremental potential in the introduction of a new demand bidding program, though given the small size of the potential it is worth considering if those resources would be better spent on other new initiatives
- Incremental growth in conventional air-conditioning DLC programs is not found to be cost-effective
- Note: We have only assessed the DR potential that is incremental to existing programs; we have not analysed the cost-effectiveness of existing programs

Existing DR Capability and Cost-Effective Potential



Notes: Potential shown for 2023. Projected 2023 peak load of 9,848 MW was used as basis for estimating % of peak impact. All impacts shown at the generator-level (grossed up for losses). A/C Rewards was launched as a pilot program in August 2017.

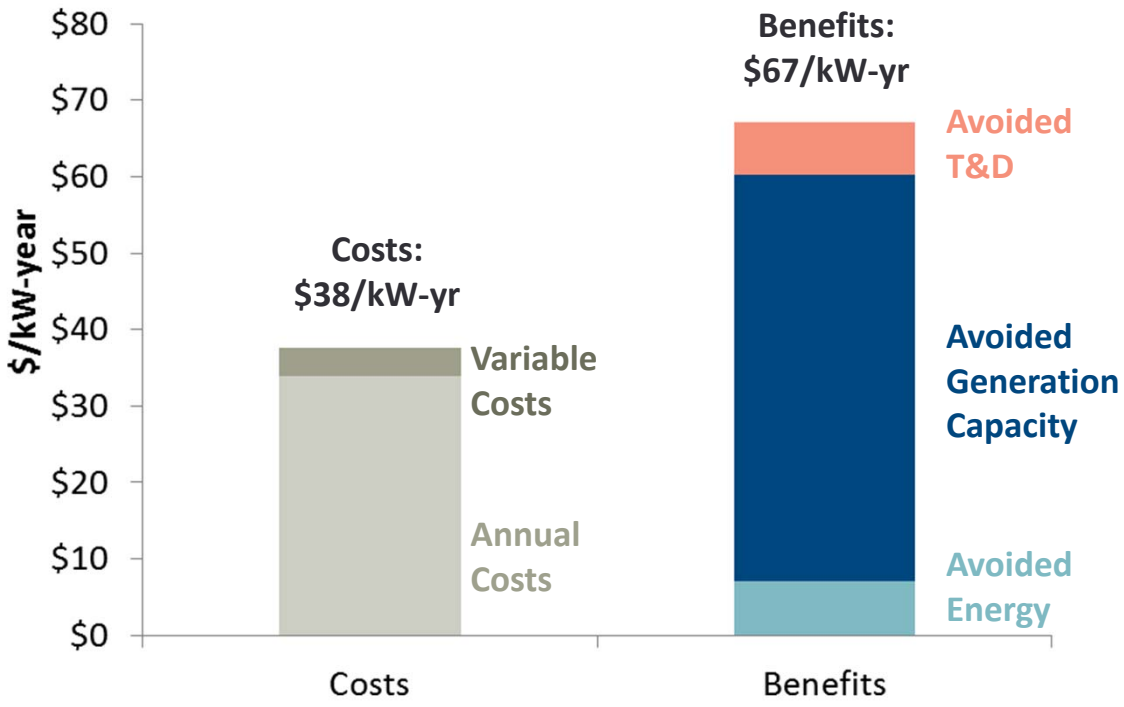
Results of Deterministic Analysis

The benefits of DR are largely avoided generation capacity costs

Comments

- The benefit-cost ratio of the portfolio of incremental cost-effective DR programs is 1.8-to-1
- Avoided generation capacity costs account for 80% of the total benefits
- The vast majority of costs are annual costs associated with participation incentive payments, program administration, and marketing/recruitment

Total Costs and Benefits of all Identified Cost-Effective Incremental DR Potential



Note: Benefits and costs are shown only for those individual DR measures with a benefit-cost ratio greater than 1.0.

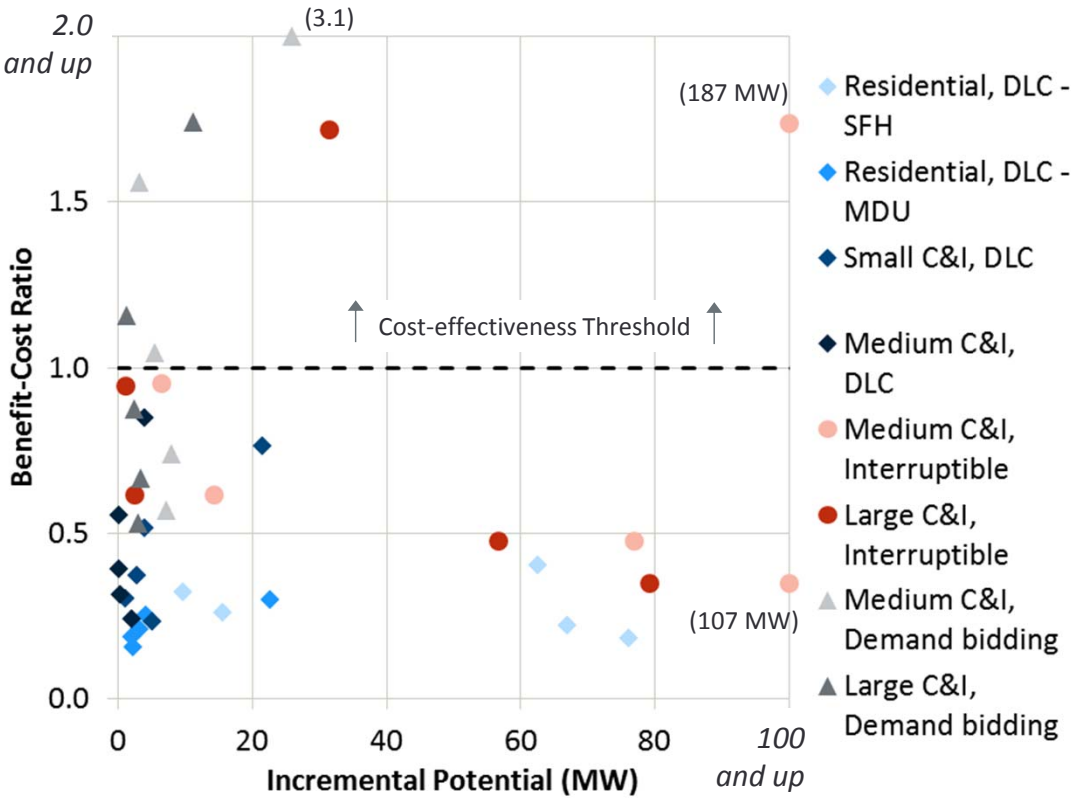
Results of Deterministic Analysis

Only a few of the analyzed programs are cost-effective

Comments

- In the chart at right, each data point represents a single incentive payment level associated with one DR program for one customer class (a range of incentive payment levels were analyzed in the 2014 Potential Study)
- Under Base Case assumptions, the most cost-effective program is Medium C&I Demand Bidding at the lowest incentive payment threshold, though the MW potential associated with this program is small
- Expanded Interruptible Tariffs have significantly more incremental cost-effective potential, particularly for Medium C&I customers, with benefit-cost ratios around 1.5

B-C Ratio and Incremental Potential of Each DR Program



Note: Each data point represents a single incentive payment level for one DR program and one customer class.

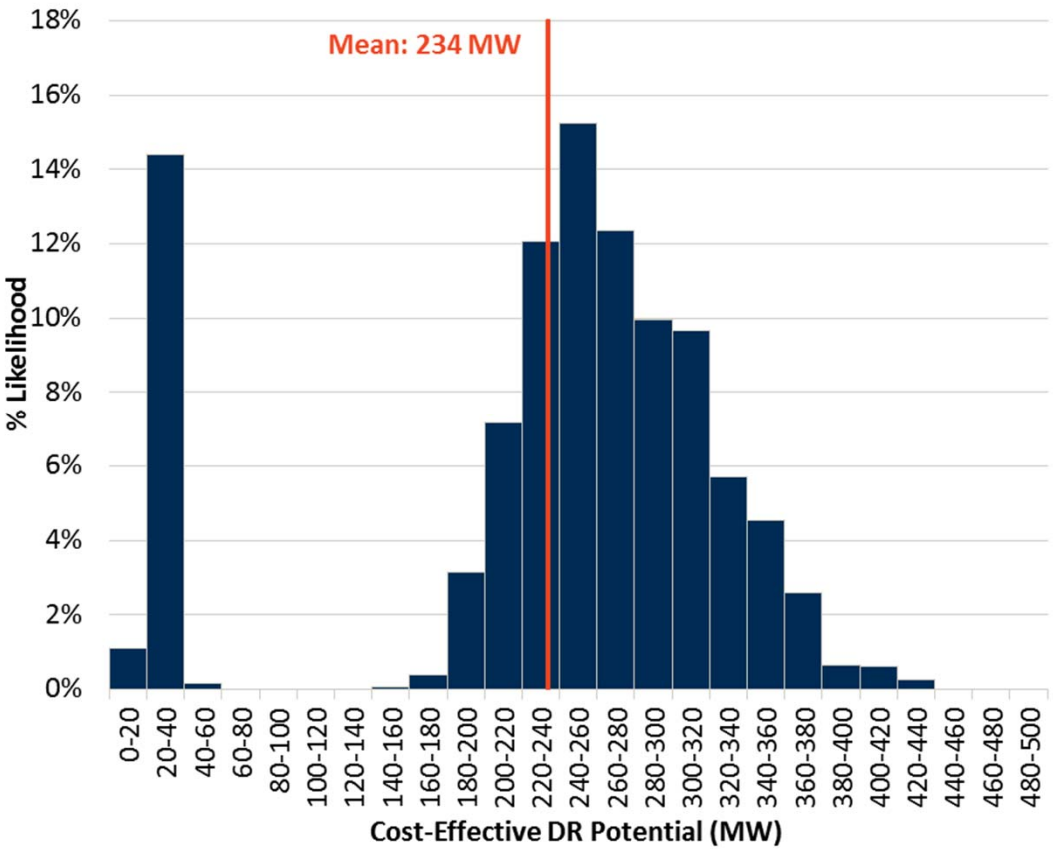
Results of Probabilistic Analysis

Accounting for uncertainty in avoided cost estimates produces consistent findings

Comments

- There is a 75% chance that cost-effective DR potential is less than 300 MW
- Whether the potential is less than 50 MW or in excess of 160 MW depends largely on whether or not the Medium C&I Interruptible Tariff program is cost-effective
- It is highly unlikely that the cost-effective potential in the programs analyzed in the 2014 Potential Study exceeds 350 MW

DR Potential Probability Distribution



Note: See Appendix B for details about the assumed range of each uncertain variable in the analysis.

Summary of findings

- NSP has already established a large portfolio of mature DR programs, which means that there are limited opportunities for incremental cost-effective growth in traditional DR
- NSP's incremental cost-effective DR potential is most likely between 200 and 300 MW
- The ability to efficiently enroll medium-sized C&I customers in an expanded Interruptible Tariff program is a key factor determining the amount of DR that is cost-effective
- This cost-effective potential of the programs analyzed in the 2014 Potential Study is less than the 400 MW to 1,000 MW target established by the PUC
- Further, there are likely to be operational challenges in achieving system peak demand reductions that are significantly beyond the capabilities of the current portfolio (i.e., an infeasible number of DR events to be called)
- Rather than pursuing a significant amount of traditional, peak demand-focused DR, there may be greater opportunities in alternative "flexible load" programs

Moving Forward with DR in Minnesota – Initial Thoughts

The cost-effectiveness findings in this presentation are not the end of the story

In spite of the limited amount of traditional incremental cost-effective DR identified in this study, there may be more value in alternative forms of demand flexibility

Renewables integration presents one such opportunity

- Minnesota has a goal of integrating 40%+ renewables
- This will require more than simple peak load reductions – it will require availability during non-peak hours, fast response times, and the ability to ramp quickly
- DR and other behind-the-meter options have the potential to provide these services

Avoided distribution costs are another emerging opportunity for DR

- There is growing interest in the use of demand-side resources to address very location-specific constraints on the distribution system
- If adequate enrollment can be achieved, it may be possible to defer the need for upgrades in locations where capacity constraints are a near-term concern
- This concept is largely in the trial phase and requires a novel approach to DR deployment and evaluation; however it is worth consideration in future DR studies

NSP's next DR potential study will include an expanded definition of DR

Which "demand flexibility" options are of interest to stakeholders?

An expanded definition of demand flexibility could possibly include:

- Distributed battery storage
- Thermal storage (incl. grid-integrated water heaters)
- EV charging control
- Some types of energy efficiency
- Bring-your-own-thermostat (BYOT) programs
- Behavioral DR
- AMI-enabled dynamic pricing

Appendix A:
Details of DR Benchmarking Analysis

Description of National DR Data

We analyzed two national DR datasets: FERC's surveys of utilities in its *Assessment of DR and Advanced Metering* Staff Reports (2006–2012) and EIA-861 Demand Response data files (2006–2015)

- In 2006–2012, FERC surveyed utilities every two years on their individual DR programs to inform its annual *Staff Report*
- The EIA has conducted the survey for many years , but annually and on aggregate DR portfolios
- Both datasets survey IOUs, munis, coops, and other load-serving entities. Shared data fields include annual capability and actual peak reduction from DR, number of customers enrolled, maximum demand from DR customers, and program costs
- To analyze DR capability as % of peak load, we also compiled peak load data reported in the EIA-861 data files

Description of National DR Data (cont.)

The FERC and EIA datasets provide information on DR penetration across utilities nationwide, but there are limitations:

- In our experience, these types of national datasets can have some reporting errors and inconsistencies
- We found the FERC survey data to more accurately represent utility DR capabilities (including NSP's) so we chose to benchmark using the latest FERC survey data available (2012)
- The % of peak metric is based on a single year of reported actual peak load
  - To the extent utilities do not adjust DR MW estimates with load, resulting % may appear high in a low load year, and low in a high load year

Peer Group Selection Criteria

We selected a subset of similarly situated utilities to compare NSP's DR portfolio to those of its peer group

MISO peer group represents large IOUs in nearby states

- Neighboring states in the Upper Midwest (MN, WI, IA, MI)
- Investor-owned utilities
- Peak demand greater than 1,000 MW

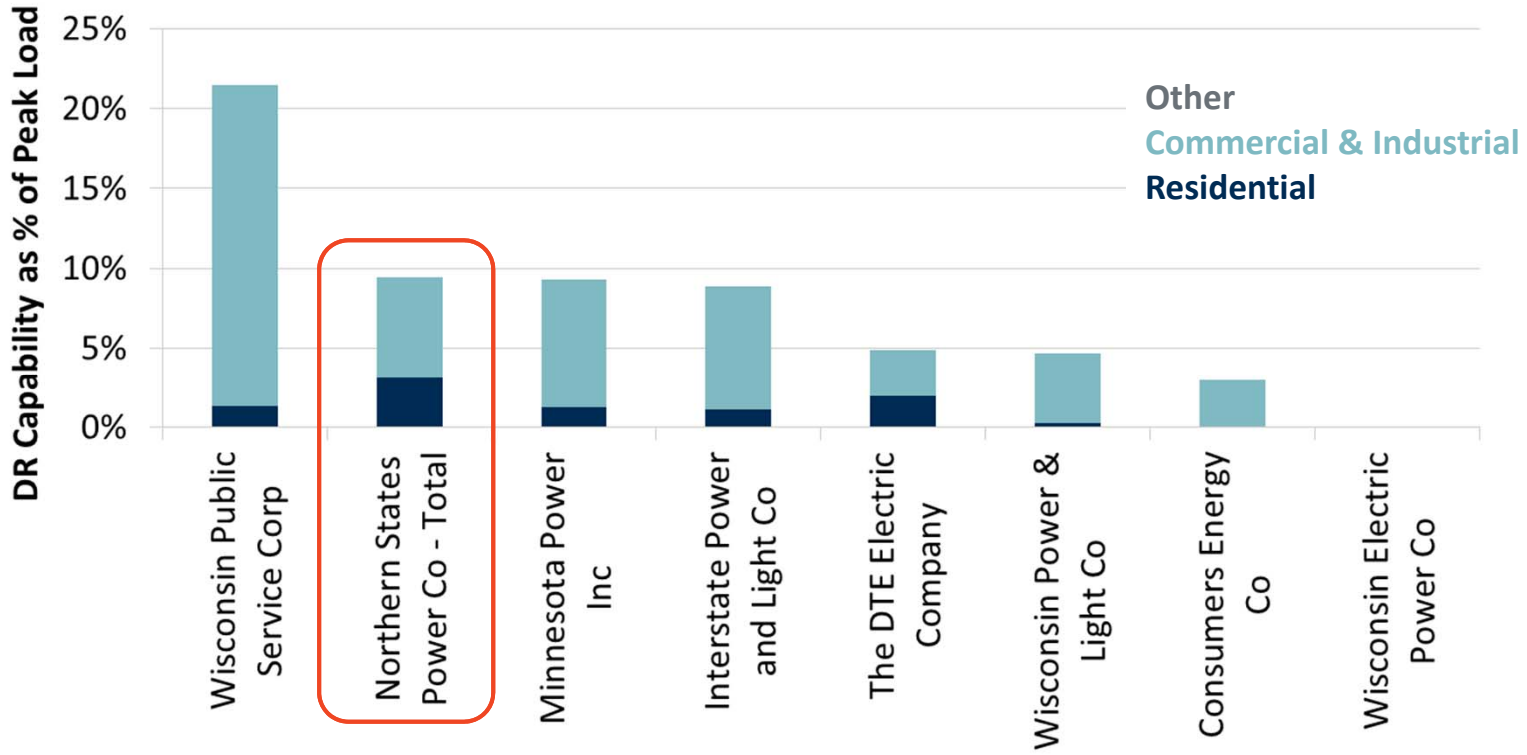
Other RTO peer group represents large IOUs with comparable peak load and serving major cities

- RTOs with capacity market (NYISO, PJM, ISO-NE)
- Investor-owned utilities serving major cities
- Peak demand greater than 5,000 MW

NSP Compared to MISO Peer Group

NSP ranks highly among MISO IOUs in total and residential DR capability.

- NSP has the most "nameplate" DR capability (830 MW) of all MISO IOUs, and ~300 MW beyond that of the next closest IOU (DTE: 550 MW, WPSC: 500 MW).
- WPSC has a larger portfolio as a % of peak demand, though lower enrollment as a % of its total customer base due to a portfolio predominantly composed of C&I

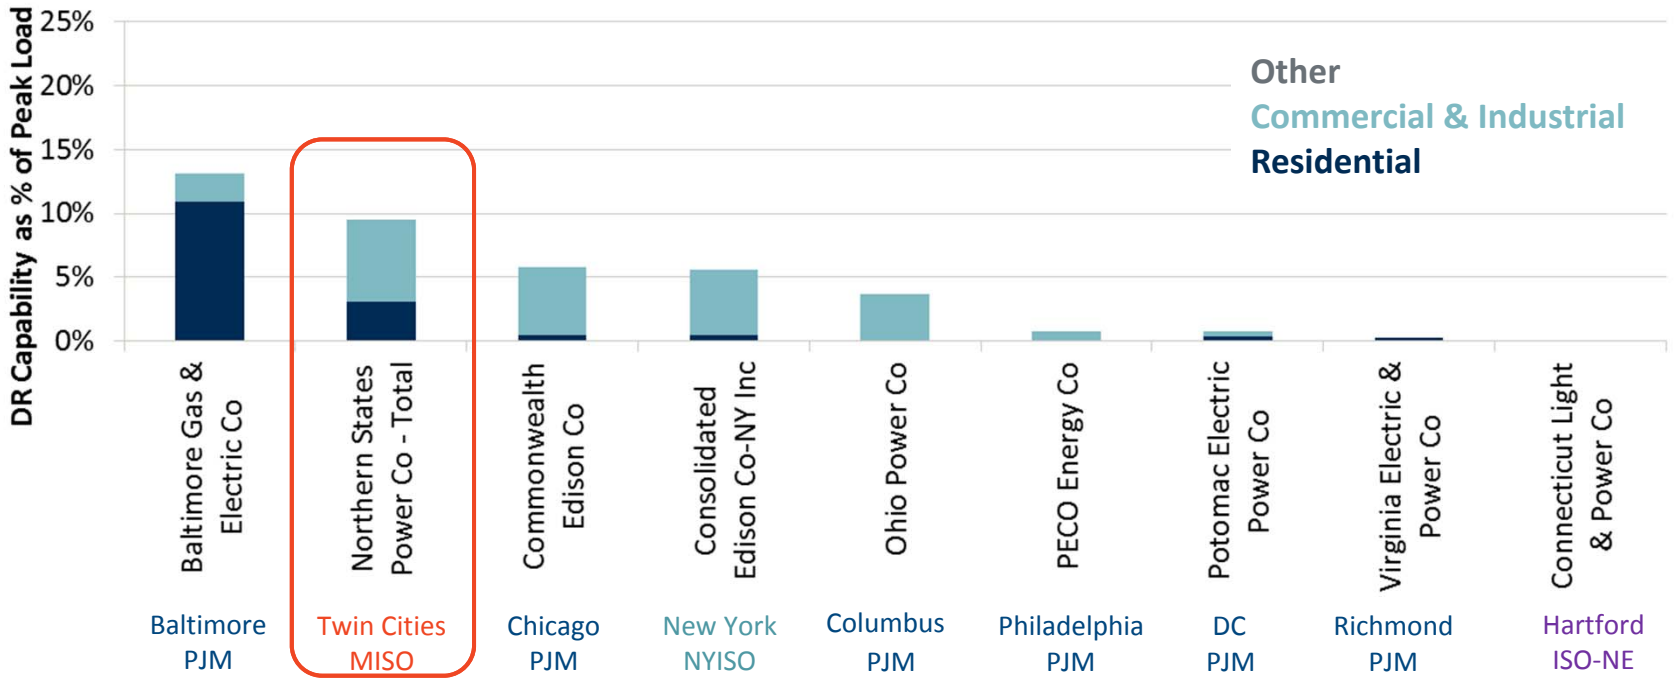


Sources and Notes: FERC, *2012 Assessment of Demand Response and Advanced Metering* and EIA 861 peak load data. Excludes peak reduction capability from time-of-use programs because these loads are not controllable. NSP's capability calculated as current portfolio divided by 2016 peak load.

NSP Compared to Other RTO Peer Group

NSP compares favorably to large IOUs in markets with more lucrative DR products (PJM and NYISO)

- BG&E (920 MW) and ComEd (1,360 MW) are the only other IOUs in peer group with comparable total MW DR capability. Outside of peer group, NSP ranks **8th** nationally in total DR capability, and **11th** nationally in DR capability as share of peak.



Sources and Notes: FERC, *2012 Assessment of Demand Response and Advanced Metering* and EIA 861 peak load data. Excludes peak reduction capability from time-of-use programs because these loads are not controllable. Share in residential DR does not control for differences in overall load composition. For example, BG&E total energy sales were 75% residential compared to NSP energy sales which were only 29% residential. NSP's capability calculated as current portfolio divided by 2016 peak load.

NSP's existing DR portfolio ranks highly against those of other large IOUs

NSP DR Capability Compared to IOU Peer Group

2012 FERC Survey

	RTO	State	Peak Load (MW)	DR Peak Reduction Capability: Total DR (MW)	Res. (MW)	C&I (MW)	**Total DR (% of peak)**	Share of DR MW: Res. (%)	C&I (%)	Customers Enrolled in DR: Res. (customers)	Total (customers)
Northern States Power Co - Total	MISO	MN	8,774	830	270	560	**9%**	33%	67%	446,808	467,161
Wisconsin Public Service Corp	MISO	WI	2,347	504	32	473	**21%**	6%	94%	25,375	25,861
Minnesota Power Inc	MISO	MN	1,633	152	20	132	**9%**	13%	87%	7,217	7,761
Interstate Power and Light Co	MISO	IA	3,130	279	34	245	**9%**	12%	88%	48,928	49,115
The DTE Electric Company	MISO	MI	11,182	547	219	328	**5%**	40%	60%	281,031	281,689
Wisconsin Power & Light Co	MISO	WI	2,851	134	7	127	**5%**	5%	95%	10,700	10,800

Wisconsin Electric Power Co	MISO	WI	6,294	0	0	0	**0%**	-	-	0	152
Baltimore Gas & Electric Co	PJM	MD	7,002	919	763	157	**13%**	83%	17%	405,944	411,064
Commonwealth Edison Co	PJM	IL	23,601	1,357	116	1,241	**6%**	9%	91%	83,537	87,312
Consolidated Edison Co-NY Inc	NYISO	NY	5,492	305	23	282	**6%**	8%	92%	22,395	32,202
Ohio Power Co	PJM	OH	9,670	351	0	351	**4%**	0%	100%	0	8
PECO Energy Co	PJM	PA	8,549	64	0	64	**1%**	0%	100%	0	118
Potomac Electric Power Co	PJM	DC	6,674	50	25	25	**1%**	50%	50%	25,000	72,769
Virginia Electric & Power Co	PJM	VA	16,787	50	50	0	**0%**	100%	0%	28,000	28,013
Connecticut Light & Power Co	ISONE	CT	5,280	5	0	5	**0%**	0%	100%	0	12
All MISO IOUs in Survey Data (12 IOUs)			55,231	2,978	718	2,260	**5%**	24%	76%	880,849	908,232
All U.S. IOUs in Survey Data (100 IOUs)			456,353	19,942	5,289	14,273	**4%**	27%	72%	4,653,575	4,838,625
All Utilities in Survey Data (387 Utilities)			563,074	27,383	7,015	19,346	**5%**	26%	71%	5,801,247	6,025,979

Sources and Notes: FERC, *2012 Assessment of Demand Response and Advanced Metering* and EIA 861 peak load data. Excludes utilities that did not participate in the FERC survey, and excludes peak reduction capability from time-of-use programs because these loads are not controllable. Res. and C&I DR do not add up to Total DR for All U.S. IOUs and All Utilities because Other DR is excluded from table. NSP's capability calculated as current portfolio divided by 2016 peak load.

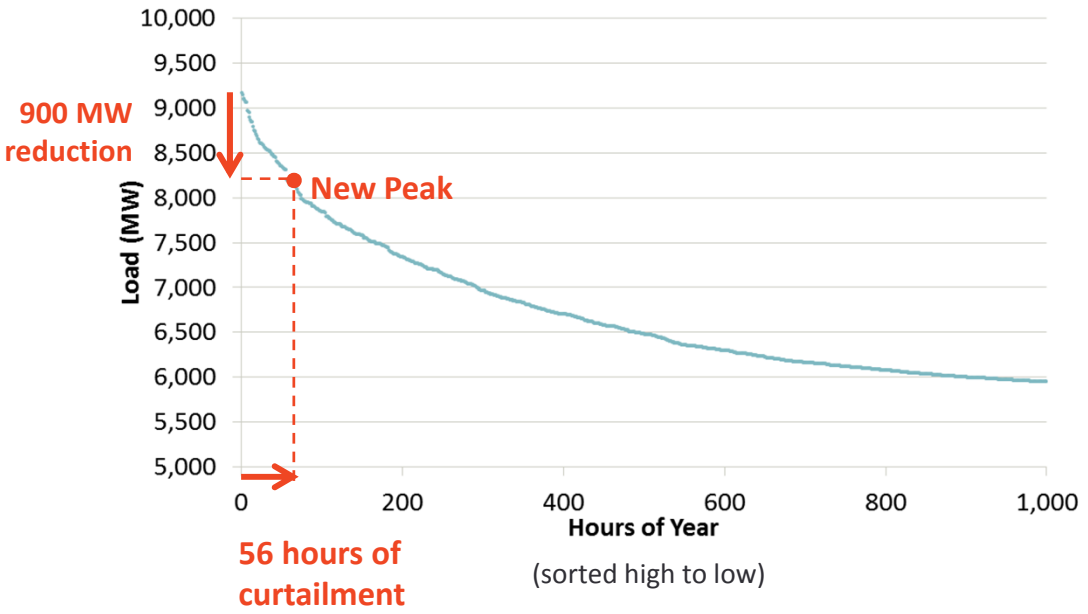
Appendix B: Additional Considerations in Assessing DR Potential

The operational constraints of DR programs have implications for the ability to reduce peak demand

Comments

- Reducing system peak demand by 900 MW (roughly the size of NSP's current DR portfolio) requires load reductions in the top **56** hours of the year
- Otherwise, one of these top **56** hours will set the new peak at a level that exceeds the target
- In 2013, those top **56** hours occurred on **8** different days of the year

NSP's 2013 Load Duration Curve



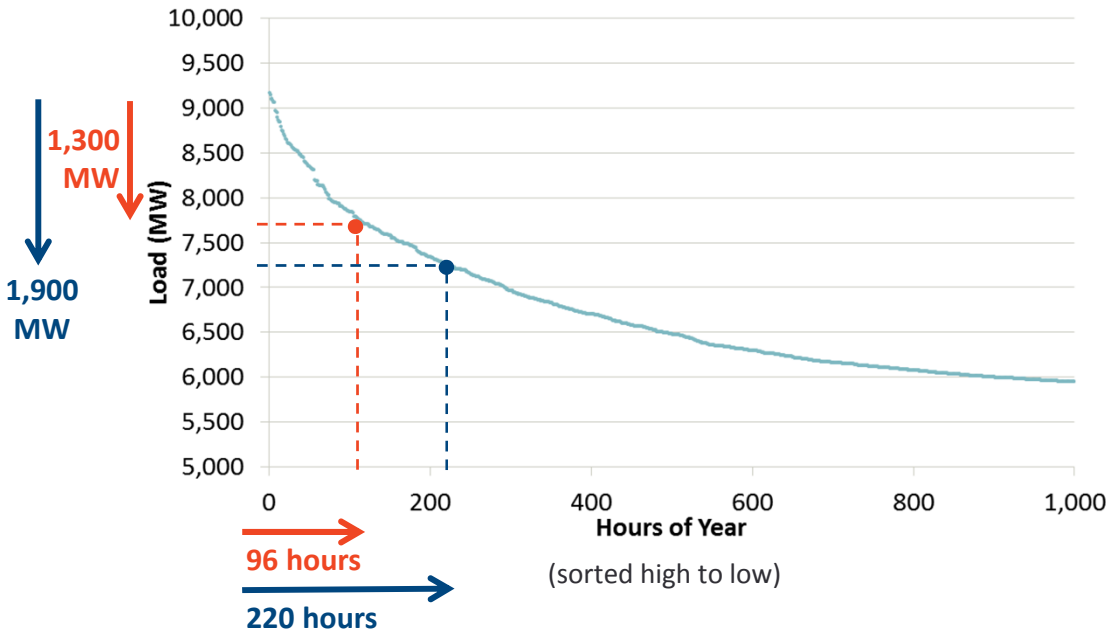
Sources and Notes: 2013 system load for NSP service territory, provided by Xcel. 2013 was chosen as the year for this example, because it was the year with the highest peak demand in the past several years.

Achieving larger load reductions requires that DR be dispatched during more hours of the year

Comments

- A **1,300 MW** reduction (the PUC's target for NSP's DR capability) would require that DR be dispatched during at least **96** hours of the year
- In 2013, those hours spanned **13** days of the year, **12** different hours of the day, and **5** days of the week
- DR events would need to be called on **5** consecutive days in this scenario
- Achieving a **1,900 MW** peak reduction would require that DR be utilized during **27** different days of the year
- The number and frequency of necessary interruptions is significantly higher in other recent years, when peak load was less concentrated in the top hours

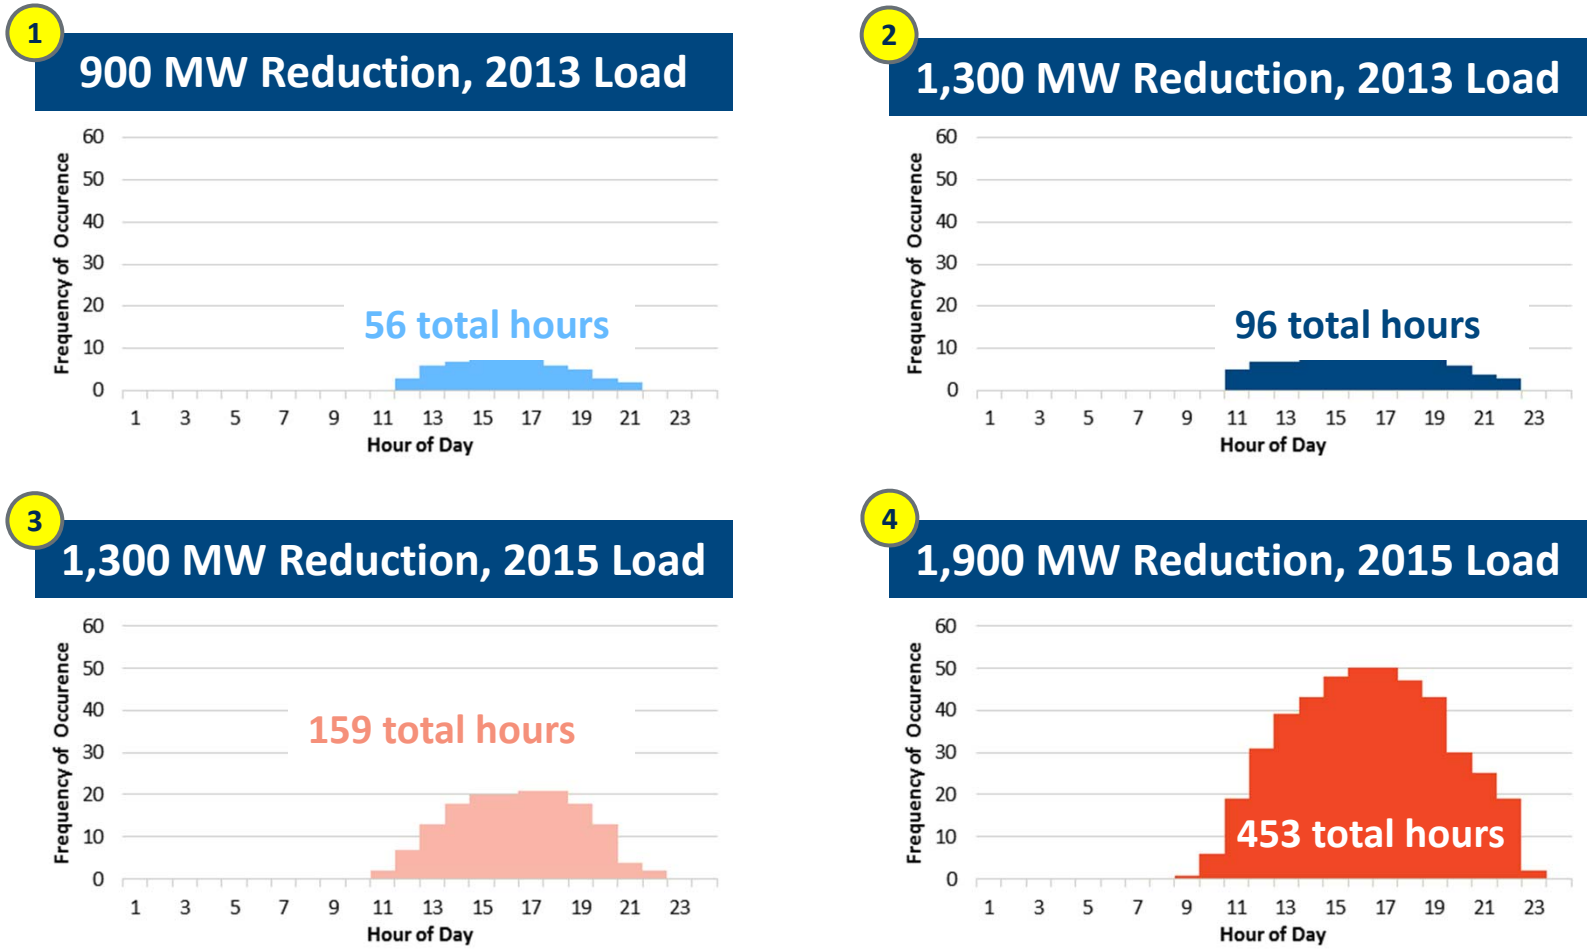
NSP's 2013 Load Duration Curve



Sources and Notes: 2013 system load for NSP service territory, provided by Xcel. 2013 was chosen as the year for this example, because it was the year with the highest peak demand in the past several years. Results will vary depending on the year being analyzed.

Achieving very large peak demand reductions will likely exceed the capabilities of traditional DR

Hours of Day When DR Would Need to be Utilized



Note: The charts illustrate the distribution of hours when a DR event would need to be called in order to achieve the specified load reduction for the specified year's load shape.

Appendix C:
Cost-Effectiveness Analysis Assumptions

Additional assumptions

Hours of generation capacity value allocation

- Base case = Top 100 load hours
- Min (probabilistic analysis) = Top 25 hours
- Max (probabilistic analysis) = Top 250 hours

Load year

- 2013, selected because it represents the highest peak demand in recent historical data (2012 through 2015) and also has the peakiest load shape, contributing to a slightly higher value of DR than other years

Planning reserve margin

- For the purposes of estimating avoided generation capacity costs, impacts are grossed up by the planning reserve margin
- This accounts for a reduced planning need
- NSP's planning reserve margin for its own system peak is 2.41% due to non-coincidence with the MISO peak

Line losses

- Impacts in the 2014 Potential Study were reported at the generator level; no gross-up was needed to account for line losses

Energy margin

- According to NSP modeling, the net energy margins (sum of marginal energy price minus the unit's variable costs over all operational hours) for a new CT in the study years is roughly between $6 and $18/kW-year
- We assume $12/kW-year, the middle of this range

Participation

- Base case impacts were based on the supply curve values produced for the 2014 Potential Study
- In an appendix to that study, we conducted a sensitivity case for each DR program's participation assumption, based on participation rates used in the 2009 FERC Assessment of DR Potential (which were based on the 75th percentile of national DR enrollment rates)
- For all but one program, the sensitivity case participation rates were lower than those used in the 2014 study
- For the probabilistic assessment in cost-effectiveness analysis, we used the absolute value of the difference between the FERC values and the 2014 Potential Study values to create upper- and lower-bound participation rates.
- The upper- and lower-bounds range anywhere from +/-5% of the Base participation rate, to +/-82%, depending on the program analyzed

Additional methodological notes

The scope of this study was only to assess the cost-effectiveness of the DR programs analyzed the 2014 Potential Study

We did not analyze time-varying pricing programs, since NSP has not deployed AMI

We have only assessed the DR potential that is incremental to existing programs; we have not analyzed the cost-effectiveness of NSP's existing DR portfolio

Our analysis is conducted from the standpoint of DR costs and benefits in 2023, the year by which the PUC has required NSP to add 400 MW of DR (and the year before the projected need for new peaking capacity, per the IRP)

Appendix D:
Additional Background

NSP's DR programs

Savers Switch:

- Central air-conditioning DLC
- Compressor switch with 15- to 20-minute cycling
- Additional option to enroll water heater
- Residential and business customers
- Residential incentive = 15% savings on energy charges (June – Sept)
- Business incentive = $5/ton of A/C (June – Sept)
- 321 MW of peak demand reduction capability (2016)

A/C Rewards:

- DLC for customer-owned smart thermostats
- Temporary modification of thermostat set point
- Residential
- Incentive = $25/yr, plus up to $125 rebate toward purchase of select smart thermostats or $75 payment for registering an installed smart thermostat
- 8 MW of peak demand reduction capability (2016)

Electric Rate Savings:

- Interruptible tariff, customer must reduce load to pre-specified level
- Medium and large C&I customers
- Minimum 50 kW demand reduction for eligibility
- Control periods can occur any time of year
- Incentive = $5.86 to $8.44 per kW of controllable load (June-Sept), $1.75 to $4.33 per kW (Oct-May)
- 501 MW of peak demand reduction capability (2016)

The 2014 DR Potential Study

The purpose of the study was to:

- Quantify the potential peak demand reduction that could be achieved through an expanded portfolio of demand response (DR) options in NSP's service territory, without cost considerations
- Identify future DR opportunities for NSP

We considered 22 different programmatic DR options and segmented the market into four customer classes

- 9 of the options were existing programs and 13 were possible new options
- 10 were considered "traditional" DR options and 12 were AMI-enabled options

We also estimated program costs which, when combined with the peak reduction estimates, produced a "supply curve" of traditional DR resources that could be used as input to NSP's integrated resource planning (IRP) process

Note: Our DR potential estimates did not account for the cost-effectiveness of the DR measures

The 2014 Potential Study (cont'd)

The following DR options were analyzed

Currently offered options

- **Direct load control (DLC):** Participant's central air-conditioner is remotely cycled using a switch
- **Interruptible rates:** Participants agree to reduce demand to a pre-specified level and receive an incentive payment in the form of a discounted rate
- **Time-of-use (TOU) rates:** NSP currently offers TOU rates, which are replaced in our analysis by re-designed rates (see discussion below)

Possible new options

- **Demand bidding:** Participants submit hourly curtailment schedules on a daily basis and, if the bids are accepted, must curtail the bid load amount to receive the bid incentive payment or may be subject to a non-compliance penalty
- **Critical peak pricing (CPP) rates:** Provides customers with a discounted rate during most hours of the year, and a much higher rate (typically between 50 cents/kWh and $1.00/kWh) during peak hours on up to 10 or 15 days per summer; can be offered with "enabling technology" which automates load reductions in response to the higher priced hours
- **Redesigned time-of-use (TOU) rates:** Existing TOU rates were redesigned to be more manageable and targeted, with a shorter peak period and a revised peak-to-off-peak price ratio

Xcel Energy Demand Response Offerings

2017-2019 Stakeholder Engagement Process Summary Report

MN PUC Docket No. E-002/RP-19-368

May 2019

Co-convened by the Great Plains Institute and Center for Energy and Environment

About this Report

AUTHOR

Trevor Drake, Great Plains Institute

ATTRIBUTION OF COMMENTS

This document provides a synthesis of remarks by stakeholders at seven meetings between December 2017 and January 2019. The notes do not indicate consensus among the group, but rather are meant to capture the collective discussion and key points raised by participants. No view should be attributed to any specific individual or organization.

The stakeholder engagement process and this resulting summary are intended to support, but not replace, important discussions within the formal regulatory process. Comments summarized as part of this report represent a perspective at a specific point in time and are not intended to limit the ability of any party to take any position in future regulatory proceedings.

ACKNOWLEDGEMENTS

GPI and CEE would like to thank Xcel Energy for the opportunity to serve as third-party facilitators for this stakeholder engagement process. We would also like to thank the stakeholders and speakers who attended and thoughtfully participated in the seven meetings that were convened as part of this process.

ABOUT THE CO-CONVENERS

Great Plains Institute: A nonpartisan, nonprofit, Great Plains Institute is transforming the energy system to benefit the economy and environment. For the last 20 years, the institute has worked on energy solutions that strengthen our communities, grow the economy, and improve lives while reducing emissions. More information is available at www.betterenergy.org

Center for Energy and Environment: The Center for Energy and Environment is a clean energy nonprofit with special expertise in energy efficiency that stretches back nearly 40 years. CEE provides a range of practical and cost-effective energy solutions for homes, businesses, and communities to strengthen the economy while improving the environment. More information is available at www.mncee.org

I. Introduction

BACKGROUND ON DEMAND RESPONSE

Across the United States, profound changes are affecting the way that electric systems are being planned and operated. These changes include a shift away from power generation from large power plants towards greater deployment of variable, distributed electricity generation from wind and solar, increasing demand for electrified transportation and buildings, a desire for more consumer choice, and pressure to reduce carbon emissions and environmental impacts. Utilities, their regulators, and energy system stakeholders across the nation are grappling with how to address these changes and pressures while attending to the need to operate electric systems safely, reliably, and affordably.

Demand response encompasses a broad set of technologies and approaches that are used to modify customers' demand for electricity to provide system-level services. Demand response programs have the capabilities to help respond to many, if not all, of the profound changes and pressures affecting the electric system today. While demand response has historically been used to incentivize customers to curtail their demand for electricity during emergency events, it can also be used for other purposes, including enhancing overall reliability, reducing operations costs by deferring or avoiding infrastructure investments, shaping loads to accommodate variable electricity generation resources like wind and solar, providing choice to customers in how much they pay for electricity based on when they use it, and providing ancillary services such as frequency regulation.

Electric utilities across Minnesota already operate several demand response programs, ranging from interruptible tariffs that provide commercial and industrial customers a lower electricity rate in return for the ability to curtail demand during emergency events, to electrified home water heaters and air-conditioners that can be controlled by utilities to manage aggregated residential electricity loads across many customers at once.

DEMAND RESPONSE REQUIREMENT FOR XCEL ENERGY IN MINNESOTA

In its January 11, 2017 Order approving Xcel Energy's 2016-2030 Resource Plan, the Minnesota Public Utilities Commission required the electric utility to include in its next resource plan the procurement of 400 megawatts of additional demand response resources by 2023 and to evaluate the cost-effectiveness of 1,000 MW of additional demand response by 2025. In December 2017, Xcel Energy hired the Great Plains Institute (GPI) and Center for Energy and Environment (CEE) to convene stakeholder meetings to solicit input on the development of its demand response offerings towards achieving compliance with the Commission's order. Xcel Energy also hired The Brattle Group to conduct an updated demand response potential study including cost-effectiveness analysis, which became available near the end of the stakeholder engagement process.

This report summarizes key points of discussion and feedback received throughout the stakeholder engagement process, which took place across seven meetings from December 2017 to January 2019.

II. Process Overview

ORIGINAL PROCESS GOALS

Beginning in December 2017, Xcel Energy initially established the following goals to help guide the stakeholder engagement process that would be co-convened by GPI and CEE:

- Create a base understanding of demand response efforts in Minnesota compared to other areas of the nation.
- Discuss the scope of demand response efforts in Minnesota.
- Provide an opportunity to share ideas amongst stakeholders regarding demand response efforts within and outside Xcel Energy's service territory.
- Brainstorm new and updated program ideas for Xcel Energy's portfolio.
- Examine opportunities and challenges to new demand response technologies and any policy changes needed for success.

PROCESS REVISIONS

The above set of goals provided a helpful and broad starting point for stakeholder discussions. However, after the first two meetings, it became clear that it would be most valuable to focus stakeholder discussions specifically on the new or expanded demand response offerings that Xcel Energy could deploy to achieve compliance with the Commission's order. Therefore, after the second meeting, GPI, CEE, and Xcel Energy worked together to restructure the process around the following revised set of goals:

1. Identify a set of consensus-based design characteristics for any new or expanded demand response program or portfolio or programs.
2. Understand and discuss the results of The Brattle Group's demand response potential study in the context of the proposed design characteristics.
3. Apply the design characteristics to the list of Xcel Energy's potential new and expanded demand response programs and identify which programs comport with the agreed-upon design characteristics.
4. Review and offer feedback to the demand response programs that Xcel Energy is developing to comply with the commission's order, considering both the design principles and the results of the potential study.

This report details the group's progress in working to achieve these goals. Importantly, Xcel Energy stated to the group that their next Resource Plan will assume the additional demand response as required in the Commission's order, but that not all programs that will be deployed to achieve compliance would be fully developed by the time that the 2020-2034 Resource Plan is filed. Therefore, while the group did develop design characteristics—in the form of the Design Principles and Filing Objectives listed in this report—and discussed them with regard to Xcel Energy's proposed DR offerings, many of those offerings were still in development at the time of these meetings and could not be fully evaluated. Therefore, the Design Principles and Filing Objectives can be especially useful to provide ongoing guidance as those offerings are developed and proposed for approval.

TIMELINE AND MEETING TOPICS

Between December 2017 and January 2019, GPI and CEE convened a total of seven meetings, each covering the topics listed below. Meetings were held in-person in various locations in Minneapolis and St. Paul. Most meetings also allowed remote attendance when possible.

Meeting 1: Introduction to Demand Response

- Presentations:
  - Demand response 101 (Xcel Energy, The Brattle Group)
  - Regional transmission organizations and demand response (MISO)
  - Current utility demand response programs in Minnesota (Xcel Energy, Great River Energy)
- Discussion:
  - New demand response technologies and opportunities

Meeting 2: Demand response technologies and programs

- Presentations:
  - Current utility demand response programs in Minnesota (Otter Tail Power)
  - What XcelEnergy is currently exploring for new DR technologies and programs
- Discussions:
  - Q&A with MISO staff
  - Panel on DR technologies and programs, including enabling technologies, examples from other utility markets, and DR aggregators

Meeting 3: Demand response values, benefits, and challenges (April 2018)

- Presentation:
  - Demand response values and benefits (Xcel Energy)
- Discussions:
  - Stakeholder panel on demand response benefits and challenges (MN Department of Commerce, Citizens Utility Board, Fresh Energy)
  - What are stakeholders' objectives for Xcel Energy's additional DR offerings?

Meeting 4: Demand response cost-effectiveness; stakeholder guidance (May 2018)

- Presentation:
  - Evaluating demand response cost-effectiveness in resource planning (Xcel Energy)
- Discussion:

- What are stakeholders' design principles for Xcel Energy's additional DR offerings? (continued from Meeting 3)

Meeting 5: Demand response potential; distribution geo-targeting (August 2018)

- Presentations:
  - Demand response potential study preliminary results (The Brattle Group)
  - Demand response geo-targeting on the distribution system (Center for Energy and Environment)
- Discussion:
  - Exploring the preliminary results of the most recent demand response potential study

Meeting 6: Xcel Energy's draft demand response portfolio (August 2018)

- Presentation:
  - Draft portfolio of additional demand response offerings (Xcel Energy)
- Discussion:
  - Stakeholder feedback on Xcel Energy's draft portfolio

Meeting 7: Xcel Energy's proposed demand response programs (January 2019)

- Presentation:
  - Demand response potential study final results (The Brattle Group)
  - Proposed list of new and expanded demand response offerings (Xcel Energy)
  - Recommendations from Advanced Energy Management Alliance and Xcel Large Industrials to enable Xcel to achieve the Commission's mandate for incremental demand response in its service territory.
- Discussion:
  - Q&A on the final demand response potential study
  - Stakeholder feedback on Xcel Energy's new and expanded demand response offerings

PARTICIPATING ORGANIZATIONS

Meetings in this process were open to the public and noticed in MN PUC Docket No. E-002/RP-15-21. GPI also sent email invitations to a distribution list of parties that had expressed interest in Xcel Energy's demand response programs.

Meetings drew an average attendance of 30-40 individuals per meeting. GPI, CEE, and Xcel Energy would like to thank the following organizations for their participation in one or more (and in many cases, all) of the seven meetings. As noted above, comments summarized in this

document represent the collective insights of stakeholders who attended these meetings and should not be attributed to any specific organization or individual.

- MISO
- Advanced Energy Management Alliance
- Center for Energy and Environment
- Citizens Utility Board of Minnesota
- Fresh Energy
- Great River Energy
- Landis+Gyr
- LLS Resources, LLC
- Minnesota Department of Commerce
- Minnesota Municipal Utilities Association
- Minnesota Pollution Control Agency
- Minnesota Power
- Minnesota Public Utilities Commission
- MN Attorney General's Office
- MN Department of Commerce
- MN Pollution Control Agency
- NRG Curtailment Solutions, Inc.
- Otter Tail Power Company
- Rakon Energy LLC
- Stoel Rives, on behalf of the Xcel Large Industrials
- Strategen Consulting
- The Brattle Group
- The Mendota Group, LLC

MEETING MATERIALS

All meeting materials from this process, including agendas, slide decks, resources, documents developed for the group, and meeting notes are available online at https://trello.com/b/vgrVwhQ3/xcel-energy-demand-response-workgroup.

III. Design Principles and Filing Objectives

Demand response is a complex and wide-ranging topic. Demand response programs can be designed to offer services at the distribution and wholesale market level, engage every type of customer, and relate to or overlap with other program offerings including energy efficiency and time-varying rates. Given this complexity and the fact that Xcel Energy's demand response programs were still in development at the time these stakeholder convenings took place, GPI and CEE asked stakeholders to collaborate in developing a set of consensus-based principles that could provide guidance to any new or expanded demand response offering, allowing flexibility on behalf of Xcel Energy to design programs in consideration of the parameters set by stakeholders.

Stakeholders participating in this process developed two lists—Design Principles and Filing Objectives. The Design Principles provide guidance for designing demand response programs or portfolios of programs. The Filing Objectives describe what information stakeholders would like to see when new demand response offerings are presented for consideration to the appropriate regulatory body (the Minnesota Public Utilities Commission and/or the Minnesota Department of Commerce). These two lists are interrelated and therefore intended to be taken as a package. In other words, while all stakeholders may not have supported each of these objectives or principles on their own, they found the full set acceptable.

Importantly, these are meant to be general guidelines and not absolute requirements. Just because an offering arguably complies with these does not guarantee that stakeholders will

approve of it. These simply offer a starting point for developing demand response offerings that have a higher likelihood of earning stakeholder approval in the regulatory process.

DESIGN PRINCIPLES

What would stakeholders like to see from a demand response portfolio of any size from Xcel Energy in Minnesota?

1. **Compensate demand response appropriately given the specific benefits it provides.**

   Incentives and penalties should be informed by the underlying benefits and value streams that the program is intended to achieve. It's up to the utility to find the right incentive levels that will both elicit customer action and enable the desired benefits at a lower cost than other resource options.

2. **Ensure pricing and expectations are clear, concise, and transparent for customers.**

   The utility should make efforts to ensure that customers participating in DR programs understand the program rules.

3. **Provide flexibility and options for customers.**

   Demand response programs are ultimately made possible as a result of cooperation from customers. Therefore, it's important that the utility provides offerings that allow flexibility and options for customers with different needs, while also delivering the desired system benefits.

FILING OBJECTIVES:

What would need to be true to earn stakeholder support when new or expanded demand response offerings are filed with the Commission?

1. **Be clear about the outcomes that demand response offerings are designed to achieve, and how those should be measured down the road.**

   Outcomes addressed should include cost-effectiveness, customer engagement as participation, system reliability and flexibility, carbon reduction, resource integration, and avoidance of building new assets.

2. **Fully evaluate demand response program costs and benefits.**

   Costs and benefits should be evaluated from the perspective of multiple key actors affected by demand response programs, including the utility, DR participants, ratepayers who are not DR participants, and society at-large (e.g., including public policy related impacts such as greenhouse gas emissions). This evaluation should include consideration of alternatives to achieving the same benefits (e.g., if DR is being used to

address a system need, how do DR costs and benefits compare to those of whatever alternative might be used to meet that system need?).

Demand response programs can deliver several benefits, including the following: reducing peak loads; shifting loads from high-cost times to low-cost ones; shifting loads from periods with high greenhouse gas emissions to periods with lower emissions; beneficially adding new loads with attention to costs and emissions; reducing energy and capacity costs; and reducing the costs of necessary ancillary services including frequency regulation, spinning reserves, and supplement reserves. DR programs can achieve higher levels of cost effectiveness by ensuring that programs are enabling as many benefits as possible.

The costs and benefits being evaluated may depend on the particular regulatory pathway through which a new demand response program is proposed (e.g., programs being proposed as CIP offerings may be evaluated differently than those being proposed through a miscellaneous filing).

At least one stakeholder felt that the MISO capacity auction does not provide an accurate price signal for determining the cost-effectiveness of DR offerings and that the MISO-calculated CONE (cost of new entry) should be used as a proxy. Xcel Energy staff responded that DR offerings would need to compete with the company's individual CONE, which is being updated for the upcoming IRP and is expected to be lower than the MISO value due to the availability of many brownfield sites (as opposed to more expense greenfield sites) for new CT's.[1]

3. **Address reliability and resilience of demand response offerings, as relevant.**

   Demand response proposals should include evidence to show how the proposed offerings will reliably deliver the intended benefits. This evidence could include physical testing, the deployment of incentives and penalties that can arguably elicit a response from customers, and audits to confirm that a program is reliably delivering its intended benefits when called upon. In cases of entirely new offerings where showing evidence of costs and benefits may not be possible, pilot projects could be deployed to develop the needed evidence.

4. **Delineate between dispatchable and non-dispatchable demand response.**

   The group discussed the difference between "dispatchable" and "non-dispatchable" DR, but did not come to consensus on exact definitions for those terms. In general, this objectives asks Xcel Energy to differentiate between something like a time-of-use rate, which could be considered a DR offering but is arguably not dispatchable (i.e., it can't be called upon to reduce load in an emergency event), and something like critical peak pricing, which is arguably dispatchable to reduce load when needed. Some stakeholders questioned the extent to which non-dispatchable offerings qualify as demand response.

[1] Meeting 4 Notes, pages 3-4, available online at https://trello.com/c/aNqgmBv4/4-meeting-4-dr-design-principles-objectives-and-cost-effectiveness-5-1-2018

In addition, some stakeholders asked that Xcel Energy clarify which demand response offerings, and how much of those offerings, are accredited in MISO.

5. **Show transparency towards meeting the objectives listed above.**

   For all of the filing objectives above, Xcel Energy is more likely to earn support from stakeholders by showing or explaining its efforts to meet these objectives as transparently as possible.

6. **Consideration of the AEMA/XLI Recommendations**

   The Advanced Energy Management Alliance (AEMA), which represents the interests of demand response service providers, including aggregators and the end-use consumers who ultimately provide demand response resources, was one of the organizations that provided dedicated stakeholder participation to this process. AEMA partnered with Xcel Large Industrials (XLI), a group of Xcel's largest industrial customers who are represented in regulatory matters by the law firm Stoel Rives LLP, to develop a set of recommendations for what they would like to see reflected in Xcel Energy's DR offerings based on discussions during this process.

   GPI and CEE, at the request of AEMA and XLI and with consent from Xcel Energy, distributed a document listing those recommendations in advance of the seventh meeting. Facilitators also allowed AEMA and XLI to present their recommendations to the group at that meeting.[2]

   Most of the best practices that AEMA and XLI recommended were in alignment with the group's previously developed Design Principles and Filing Objectives, though their recommendations offered much more specific detail. The one best practice area that differed most notably from the group's Design Principles and Filing Objectives was in regard to the utility's use of third-party DR service providers.[3] AEMA and XLI argue in their written proposal that demand response aggregators can offer services that benefit both customers and the utility, ultimately making DR programs more effective. [4]

   The appropriate use of third parties to support Xcel Energy's demand response efforts was a theme that arose in several discussions throughout the stakeholder engagement process. and may be worth considering when new or expanded demand response offerings are proposed for approval.

[2] The recommendations document and associated slide deck from AEMA and XLI are available online at https://trello.com/c/qvtlayfB/23-meeting-7-wrap-up-1-22-2019

[3] AEMA proposals mirror the "Indiana Model" for consumer and aggregator participation in DR programs. Under the Indiana model, aggregators act as an intermediary between the utility and the customer, bringing the customer's load drop capabilities to the utility, and the utility will then, if appropriate, register the load drop capabilities with the ISO. Under this approach, there is no infringement on the state's prior decisions under FERC order 719

IV. Demand Response Potential Study

BACKGROUND ON THE STUDY

To support both its own efforts to comply with the commission's requirement and stakeholder discussions under this process, Xcel Energy hired The Brattle Group to conduct a study of demand response potential in its Northern States Power (NSP) service territory.

The Brattle Group had conducted a previous study in 2014 that looked only at DR technical potential, which was the basis for the Commission's requirement. This more recent study looked beyond that technical potential, evaluating both cost-effective potential—in which demand response program costs, equipment costs, and incentives must outweigh avoided resource costs—and achievable potential, which estimated program enrollment rates based on local and national market research.

This new study sought to "estimate the potential capability of all cost-effective demand response (DR) that could be deployed in Xcel Energy's Northern States Power (NSP) service territory through 2030," including mid-point analyses at the year 2023, which was the deadline for procuring 400 MW of additional DR as required by the Commission, and the year 2025, which was the commission's deadline for evaluating the cost-effective achievability of 1,000 MW of additional DR.[5]

The study included two scenarios for evaluating DR deployment under different sets of assumptions – a Base Case and a High Sensitivity Case. The study states, "The Base Case most closely aligns with NSP's expectations for future conditions on its system, as defined in its IRP. The Base Case represents a continuation of recent market trends, combined with information about known or planned developments during the planning horizon."

By comparison, "The High Sensitivity Case was developed to illustrate how the value of DR can change under alternative future market conditions. The High Sensitivity Case is defined by assumptions about the future state of the NSP system and MISO market that are more favorable to DR program economics."[6] Importantly, the study notes that the High Sensitivity Case "is not a forecast of what is likely to happen in the future in NSP's service territory, particularly in the near-term years of the study horizon."[7]

[5] Ryan Hledik et al., *The Potential for Load Flexibility in Xcel Energy's Northern States Power Service Territory,* (The Brattle Group, January 2019), i, available online at https://trello.com/c/qvtlayfB/23-meeting-7-wrap-up-1-22-2019

[6] Ibid, iv

[7] Ibid, iv

INTERPRETING THE COMMISSION'S REQUIREMENT

Importantly, the study lists two clarifications around interpreting the commission's 400 MW requirement. The first is that there are three ways to measure demand response – at the capacity level, the generator level, and the meter level:

> 1 MW of load reduction at the meter (or customer premise) avoids more than 1 MW at the generator level due to line losses between the generator and the customer. Further, 1 MW of load reduction at the generator level provides more than 1 MW of full capacity-equivalent value, as the load reduction would also avoid the additional capacity associated with NSP's obligation to meet the planning reserve requirement. Based on NSP's calculations, which account for line losses and the reserve requirement, 1 MW of load reduction at the meter level equates to 1.08 MW of load reduction at the generator level and 1.11 MW of capacity-equivalent value.[8]

The report then states that while "NSP has interpreted the PUC's Order to require 400 MW of capacity-equivalent DR," the report itself assesses the commission's "procurement requirement as a 391 MW generator-level value unless otherwise specified."[9] To be consistent, this section of the stakeholder process summary uses demand response capability values that align to the report's 391 MW generator-level interpretation of the commission's 400 MW requirement.

The second clarification is that the requirement set by the commission was established based the 2014 potential study, when Xcel Energy had 918 MW of demand response capability. Much of this newer study looks at incremental DR potential from a lower 2018 baseline of 850 MW of DR capability. This reduction in the baseline is due to program right-sizing that took place after 2014, in which customers on interruptible tariffs were tested to check their ability to comply with the requirements of those tariffs and subsequently removed from the tariffs if warranted.[10]

The effect of this baseline change from 2014 to 2018 is that in order to meet the commission's requirement, Xcel Energy must procure an additional 459 MW of generator-level DR from the 2018 baseline, adding up to a total generator-level demand response capability of 1,309 MW by 2023.

RESULTS AND STAKEHOLDER DISCUSSION

With regard to the commission's 2023 requirement, the study concluded that under the Base Case assumptions Xcel Energy could cost-effectively deploy 306 MW of additional generator-level demand response by 2023 from a 2018 baseline, falling short of the Commission's 459 MW requirement (adjusted from the original 400 MW value as noted above). This was partly due

[8] Ibid, 17

[9] Ibid, 17

[10] Ibid, 18

to the assumption that advanced metering infrastructure (AMI) would not be fully deployed in 2023, an item that was of interest to stakeholders and is described in more detail below.

Beyond the 2023 deadline, the study found that, under the Base Case assumptions and with full AMI deployment in 2024, Xcel Energy could deploy "1,243 MW of cost-effective DR potential in 2025."[11] This quantity would be close to, but still short of, the incremental 459 MW (1,309 MW total potential) requirement for 2023. Looking out to 2030, the Base Case assumptions yielded 468 MW of incremental cost-effective DR, adding up to a total portfolio 1,318 MW.[12]

Staff from The Brattle Group presented preliminary results from the study at Meeting 5 and final results at Meeting 7. While the opportunity to discuss the study during meetings was clearly valuable to stakeholders, it seemed to facilitators that more time could have been useful to understand the study results in-depth. To support ongoing conversation and complement the information contained in the study, we have described below the topics that appeared to be of most interest to stakeholders during Meetings 5 and 7, including examples of specific issues or questions that were raised.

Avoided capacity costs

In order for demand response to be cost effective in the study, the sum of its program, equipment, and customer incentive costs would have to outweigh the cost of an avoided resource. Therefore, the assumed cost of an avoided resource was of particular interest to stakeholders because it serves as a threshold that demand response must pass to be considered cost effective.

As noted above under Filing Objective 2, Xcel Energy's cost of a new natural gas generation resource is significantly lower than national averages due to the availability of brownfield sites that reduce development costs for new turbines. This was a concern for some stakeholders. The study addresses this difference by looking at demand response potential under two different avoided capacity costs: Xcel Energy's assumed cost in its 2018 integrated resource plan of $64/kW-yr for the base case, and the U.S. Energy Information Administration's 2018 Annual Energy Outlook assumed cost of $93/kW-yr for the high sensitivity case.[13]

Cost-benefit analysis

In alignment with Filing Objective 2, many stakeholders wanted to better understand how the costs and benefits of demand response were analyzed in the study, in comparison to traditional forms of generation such as natural gas plants. In particular, some participants were interested in the assumptions around the operational constraints of

[11] Ibid, iii

[12] Ibid, iv

[13] Ibid, 13

demand response programs (e.g., the ability to actually elicit the required response from customers when needed, with attention to the necessary frequency and duration of that response).

Staff from The Brattle Group responded that they analyzed demand response costs and benefits by taking Xcel Energy's assumed cost of providing capacity through traditional generation (e.g., $63/kW-yr in the base case) and allocated that cost across the 100 hours of the year when electricity demand was most likely to be at its peak. This takes the annual avoided capacity cost and turns it into an hourly capacity cost that demand response must beat to be cost-effective in each of those hours. The Brattle Group's model then attempts to dispatch demand response in those hours instead of traditional generation, accounting for DR costs, operational constraints such as the inability to use air conditioning demand response programs in winter and additional values, such as deferral of transmission and distribution investments. Additional details of the cost benefit analysis are included in the study.

Incentive levels for existing program participants

One key clarification that arose through stakeholder discussion was that the study looked only at the costs to acquire *new* demand response program participants, either through entirely new programs or through the acquisition of new participants for existing programs. However, the study did not look at adjusting incentive levels or changing program designs for existing DR participants. Some stakeholders were concerned that so doing may have excluded potentially significant additional capacity of cost-effective DR and certainly excluded analysis of existing customer capacity beyond emergency-only interruptions. While any changes for existing program participants were outside the scope of this study, this issue may be worth considering as changes to existing demand response programs are proposed in the future.

Advanced metering infrastructure

Stakeholders were interested in how advanced metering infrastructure (AMI) was included in the potential study because it's a foundational technology that enables several demand response programs, including time-varying rates and critical peak pricing. With no residential advanced metering infrastructure currently deployed or planned other than for the residential time-of-use pilot that will commence in 2020, the study assumed that NSP would not achieve full AMI deployment until 2024. This was a factor in the study's finding that Xcel Energy could not cost-effectively achieve 459 MW of additional demand response by 2023 from a 2018 baseline.

Participants were also interested in assumptions around the costs of AMI. One of the challenges with addressing those costs is that AMI can be used to support many programs and services, demand response being only one of them, so it is difficult to assign a portion of the total investment in AMI to demand response programs alone. The Brattle Group staff explained that while AMI was assumed beginning in 2024, its costs were not included in the assessment of DR program costs.

The impact of this on the study is that programs that rely on AMI after 2024 may appear more cost effective than if a portion of the investment in AMI was included in their costs. Some stakeholders were interested in further discussing AMI investment costs, but

acknowledged that such a discussion might be better suited to a conversation outside of these demand response-specific meetings.

Transition from Saver's Switch to smart thermostats

In both Meeting 5 and Meeting 7, stakeholders were curious to know more about a shift that the study predicted between 2017 and 2023, in which current participants in the Saver's Switch program leave to become participants in smart thermostat programs. The Brattle Group staff explained that utility-controllable smart thermostats offer more sophisticated demand response controls over Saver's Switch, such as the ability to pre-cool spaces and coast through an event, rather than simply cycling A/C units during the event. Further, since the two programs control the same devices (i.e., A/C units), customers may not participate in both.

This transition between the two different technologies leads to a net increase of 114MW of demand response—roughly one third of the cost-effective demand response capacity that could be deployed before 2023.[14] The Brattle Group staff also noted that while these programs are offered to residential, commercial, and industrial customers, most of the increase is due to residential customers buying smart thermostats.

Full consideration of value streams, including ancillary services

Participants were interested in finding out whether and how DR value streams beyond avoided capacity were analyzed, including transmission and distribution deferral and ancillary services such as frequency regulation. Staff from The Brattle Group explained that up to 2023, most of the value attributed to demand response comes from deferred capacity investments. However, the study's High Sensitivity Case looks at the value of additional benefits from ancillary services towards 2030, including a doubling of the need for frequency regulation as well as additional need for transmission and distribution deferral. Staff from The Brattle Group clarified that frequency regulation is the only ancillary service that was modeled because it provides the greatest value to demand response.

Full consideration of newer demand response programs

The Brattle Group's study considered eight new demand response program options, but found that only smart water heating could cost-effectively be deployed before 2023.[15] Some stakeholders were interested in knowing more details about how these newer programs were considered. In particular, participants asked about behavioral demand response (in which customers receive non-monetary positive feedback for reducing their electricity usage in response to a notice) and heat pump space and water heating.

For behavioral demand response, which was not found to be cost effective under any of the cases modeled, The Brattle Group staff explained that they looked at studies and

[14] This value was initially presented as 105 MW in Meeting 5 (Brattle deck slide 11) and was later updated to 114 MW in the final version of the potential study.

[15] Hledik et al., Potential for Load Flexibility, 19-21

spoke with O-Power, a behavioral demand response service provider, to better understand the per-customer costs of running those programs. For heat pump space and water heating, the research team explained that they considered it, but didn't include it in the study for two reasons: first, that most of the benefits are efficiency rather than demand response; and second, that penetration of electric heat pumps is currently too low to warrant its inclusion, though that could change in the future. However, the study does include electric resistance water heaters, which currently have a more substantial market penetration.

V. Xcel Energy's Demand Response Offerings in Development

At the sixth stakeholder meeting in August 2018, Xcel Energy presented for feedback an initial list of demand response programs under development to meet the commission's requirement. This included eight residential DR programs, five programs for large commercial and industrial customers, and six programs for small/medium commercial and industrial customers.

INITIAL FEEDBACK

In response to the offerings presented at Meeting 6, stakeholders said that the list of programs seemed to strike a balance between traditional DR and forward-looking, innovative programs. They also said that Xcel Energy seemed to be looking at the right general buckets of opportunities. However, several stakeholders stated that they would need much more detail to be able to fully evaluate Xcel Energy's DR offerings. Below, we have summarized the general requests for more information that were raised during Meeting 6:

Contribution to Commission Requirement

The programs presented at Meeting 6 did not include estimated DR capabilities in terms of megawatts, so some stakeholders wanted to know how each program would contribute to the commission's requirement. As noted below, Xcel Energy provided initial estimates for these numbers in Meeting 7.

Cost-Effectiveness and Potential Study

Stakeholders desired to know more about the cost-effectiveness of each program being developed, and how that cost-effectiveness was derived, whether based on sensitivities in The Brattle Group's potential study or through another method. Some parties wanted additional information about how cost-effectiveness of DR programs would be represented in the forthcoming integrated resource plan. It was also noted that cost-effectiveness is determined differently depending on the regulatory process being used to seek program approval – another piece of information that stakeholders desired and is described further below.

Regulatory Process

Some stakeholders wanted more information about which regulatory process(es) would be used to seek approval for each DR program. Accordingly, parties were interested in cost-effectiveness tests (as notes above) depending on the regulatory vehicle being used as well as how measurement, verification, and reporting protocols would be executed.

Advanced Metering Infrastructure (AMI)

Stakeholders had several questions about advanced metering infrastructure in relation to new demand response offerings, including how AMI deployment would impact the timing and pricing of each offering and whether these offerings would be used to justify investment in AMI.

Alignment with Filing Objectives and Design Principles

Some stakeholders wanted more information about whether and how each program aligned with the group's Filing Objectives and Design Principles. In particular, some participants at Meeting 6 were concerned that the programs seemed fragmented, potentially limiting customer choice and compensation for flexibility. There was also a question raised about which programs are dispatchable (i.e., in the utility's control) versus those that affect load shape but cannot be actively controlled by the utility, such as time-varying rates.

Opportunities for Aggregators

Some parties wanted to know more about the role of aggregators in the various programs that were presented, including whether and how aggregators could participate.

Consolidating Offerings

Some participants recommended combining several of the different C&I demand response offerings into a single program to encourage broad participation and avoid competition between similar offerings.

REQUEST FOR A DETAILED TABLE OF OFFERINGS

At the conclusion of Meeting 6, there seemed to be general agreement among the group that a more detailed presentation of Xcel Energy's new DR programs under development would be helpful to aid with understanding and evaluating the offerings, both individually and as a total package. Several stakeholders suggested that Xcel Energy come back to the group with a table listing the various offerings, their alignment with the Filing Objectives and Design Principles, and responses to the pieces of information requested above.

In response, Xcel Energy staff offered to develop the table and provide as much information as they could, based on availability of that information and timing constraints. Xcel Energy staff presented the table for review at the seventh and final meeting in January 2019. Below, we have listed the specific items that stakeholders asked Xcel Energy to provide and a summary of

the information that was available in response. We have also included a summarized version of the table itself.[16] Since these items were of interest to stakeholders during these meetings, it's likely that they'll be of interest as program move through the regulatory approval process.

1. **Provide a name and short description of the offering**

   The table listed 20 individual demand response offerings under development, each with a short description.

2. **Provide a narrative explaining how it complies with the group's Filing Objectives and Design Principles.**

   The table included columns that respond to many of the Design Principles and Filing Objectives, though some of the information was not yet available.

3. **What is its contribution to meet the commission's requirement?**

   The table listed estimated DR capability values in megawatts for each program area based on the Brattle Group's potential study, adding up to a total of 271 MW. The values were representative of the incremental load available when DR programs are offered simultaneously as part of an overall portfolio, and therefore were provided by program type rather than for each specific program. Xcel Energy noted that these were initial placeholders and would fluctuate as programs are further developed.

4. **Is it expected to be cost effective?**

   There are two cost-effectiveness columns – one based on whether the program was deemed cost effective based on avoided capacity costs; the other is based on an additional a cost-benefit analysis that was not yet available.

5. **Is it dispatchable or non-dispatchable?**

   This was included for each offering.

6. **Does it utilize AMI (to help justify the cost of investing in AMI)?**

   This information was not yet available.

7. **Does it have energy efficiency benefits?**

   This was included for each offering.

8. **What evidence is there of customer interest in the program?**

   This information was not yet available.

9. **What regulatory process(es) will be used to seek approval, and are there specific conflicts or risks anticipated?**

   This information was available for some of the programs and unavailable for others.

10. **What role, if any, is there for demand response aggregators?**

[16] The full table is available online in both PDF and Microsoft Excel formats at https://trello.com/c/qvtlayfB/23-meeting-7-wrap-up-1-22-2019

In the table presented, one of the programs—interruptible offerings for medium and small C&I customers—was targeted for third-party aggregators.

Feedback in response to the table at Meeting 7 was limited and will need to be refined as individual offerings move through the regulatory process. Overall, stakeholders said that they thought Xcel Energy was taking a thoughtful approach to a variety of achievable programs, and that the portfolio seemed forward-thinking from the perspective of supporting resource integration in the future. Some participants inquired whether the programs could be combined into more streamlined customer offerings. Xcel Energy staff responded that streamlining would take place once the company's full demand response roadmap was complete.

Participants also had the following questions in response to the table. While these were not resolved in the meeting, they may be worth pursuing in the formal regulatory process for considering Xcel Energy's DR offerings:

- Would it make a difference to consider incremental demand response from *existing* participants, since The Brattle Group's report looked only at potential for new participants?
- What will the carbon reduction impacts be from these programs?
- How might activity at MISO affect these programs?

Table 1. Summarized Version of Xcel Energy's Demand Response Offerings in Development as of January 22, 2019

Program Type	Est. Potential (MW)	Segment	Product	Description	Est. Potential Achievement Date
Behavioral DR	-	Residential	"Hands-off" DR	Use messaging without technology to encourage DR event participation	2023
Commercial Building Controls	10	C&I, Medium	Commercial Building	Leverage EMS software to provide DR capacity & overall demand mgmt	2021
Critical Peak Pricing	41	C&I, Medium	Critical Peak Pricing (Opt-in)	Base periods are similar to TOU structure with lower energy/demand prices, but during "critical" periods customer pays higher pricing	2022
Electric Vehicles	<1	Residential	Electric Vehicle Smart Charging	MN residential smart charging pilot with L2 EVSE, proves out EE and peak load shifting, may include economic demand response	2020
			Electric Vehicles DR& Storage	Use EV's for DR and storage opportunities	2024
Interruptible Offerings	79	C&I, Medium, Small	Peak Partner Rewards	Customer receives incentives for nominated capacity and/or performance during DR events	2020
		C&I, Medium, Small	Third-Party Aggregation	Allow third-party aggregator to promote, recruit and enroll customers into DR program.	2021
		C&I, Medium	Interruptible Rates	Rate discount or credit for agreeing to reduce load during specified periods (updates to current program)	2022
Other (not included in Brattle Group potential study)	-	C&I	DERs for Ancillary Services	Use DERs to provide ancillary services	2021
		C&I	Leverage Microgrids	Leverage existing or planned microgrids for DR capacity	2022
		All	Geo-targeted Distribution	Identify stress points in distribution system & target affected customers with regular or enhanced DR offers	2019 - CEE
		TBD	Reverse DR Balance system	Load for excess renewable generation by incentivizing customers to use energy at these times	2023
		Residential	BTM Batteries/Storage	Deploy battery technology behind customer meters for DR and load capacity	2024
Smart Thermostats	112	Residential	Expand current smart thermostat program	Expand current ST offerings into other markets, existing programs, or gas DR	2021
			Home Energy Management (HEM)	Provide technology to customers that helps reduce energy usage, educates, and facilitates DR	2024
			Smart Thermostat Optimization	Deploy software to manage & optimize smart thermostat operations to improve energy savings, demand reductions, etc.	2020
Smart Water Heating	8	Residential	Water Heaters for DR	Leverage water heaters for DR capacity	2023
			Water Heaters DR using CEA-2045 connection/technology	Via a controlled demonstration, this project will provide economic justification and a plan for a market transformation	2023
Thermal Storage	-	C&I	Thermal Storage	Leverage things like refrigeration as storage devices to shift demand	2023
Updating Saver's Switch	21	Residential, Small C&I	Saver's Switch (2-way communicating)	Updating our current technology and expanding the program	2021

VI. Conclusion and Next Steps

In compliance with the Commission's requirement to procure an additional 400 MW of demand response, Xcel Energy is in the process of reviewing roughly 20 expanded and new DR program offerings in its NSP service territory.

Those offerings are based in part on a study that Xcel Energy hired The Brattle Group to conduct to identify the potential for cost-effective, incremental DR programs, which found that the company could meet some, but not all, of the Commission's required demand response capability cost-effectively by 2023. This finding was due to a series of factors, including low capacity prices, lack of advanced metering infrastructure to enable some programs, low development costs for new generation assets, and limited benefits from ancillary services and transmission and distribution deferral.

There are multiple next steps for Xcel Energy's demand response offerings for Minnesota. The portfolio as a whole will be considered in Xcel Energy's next Integrated Resource Plan filing, with an assumption of deploying enough DR to meet the Commission's requirement by 2023 for at least one of the plan options. The individual demand response programs that will be deployed to achieve that requirement are currently in development and will be brought forth for regulatory approval, though the exact details of regulatory consideration were not available at the time of these stakeholder meetings.

As those offerings are determined to move forward, the Design Principles and Filing Objectives that were collaboratively developed by stakeholders as part of this process offer a useful framework, both for providing ongoing guidance to the design of those offerings, and for evaluating them once they are finalized and submitted for regulatory consideration. To the extent that program offerings can be designed and filed in accordance with the stakeholder guidance captured in this report, they will have a higher likelihood of earning stakeholder support.

I. GREENHOUSE GASES

A. Regulation of CO_2 from Existing Power Plants

1. Clean Power Plan

The U.S. Environmental Protection Agency (EPA) in October 2015 promulgated, under Section 111(d) of the Clean Air Act, a final rule *Carbon Pollution Emission Guidelines for Existing Stationary Sources: Electric Utility Generating Units*, termed the "Clean Power Plan" (CPP).[1] At the time of our last Upper Midwest Resource Plan, the rule was final and some of our states were beginning to develop implementation plans. We discussed in that Plan how the expected CO_2 reductions under our Preferred Plan would position Xcel Energy for compliance with the CPP, under various assumptions about how our states might design their plans and allocate CO_2 allowances.

Several states and industry petitioners, led by West Virginia, filed suit at the D.C. Circuit Court to stay the CPP. The D.C. Circuit initially declined to stay the rule, but the U.S. Supreme Court stepped in and stayed implementation of the CPP in February 2016. In the interim, the D.C. Circuit Court has held the case in abeyance.

EPA estimated that at the national level, the CPP would have reduced electric sector CO_2 emissions by about 32% below 2005 levels by 2030. Xcel Energy has already exceeded this reduction, achieving approximately 34% below 2005 levels as of 2018 for our Upper Midwest system. Our Preferred Plan would take us beyond 80% below 2005 levels by 2030.

2. Affordable Clean Energy rule

EPA in October 2017 issued a proposed rule to repeal the CPP, based on its view that the CPP exceeds the EPA's statutory authority under the Clean Air Act.[2] EPA also published an Advanced Notice of Proposed Rulemaking seeking comment on whether to develop a replacement rule, and what form such a rule should take.[3] In August 2018, EPA then issued a proposed CPP replacement rule*, Emission Guidelines for Greenhouse Gas Emissions from Existing Electric Utility Generating Units*, termed the "Affordable Clean Energy" (ACE) rule.[4] The proposed rule applies to coal-fired steam electricity generating units in operation on or before January 8, 2014.

[1] 80 *Fed. Reg.* 64,662, October 23, 2015.
[2] 82 *Fed. Reg.* 48,035, October 16, 2017.
[3] 82 *Fed. Reg.* 61,507, December 28, 2017.
[4] 83 *Fed. Reg.* 44,746, August 31, 2018.

Whereas the CPP defined the Best System of Emission Reduction (BSER) to encompass CO_2 reductions achievable throughout the electricity system – including efficiency improvements at coal units themselves, switching from coal to gas, and renewable energy additions – the ACE proposal replaced this interpretation with a much narrower "inside the fence line" approach based only on heat rate improvements (HRI) implemented at the affected coal units. The proposal would require states to make unit-specific determinations of the achievable emissions reductions through HRI, expressed as an allowable emissions rate (lbs CO_2/MWh gross), and to evaluate eight "candidate technologies" for HRI: neural network/intelligent sootblowers, boiler feed pumps, air heater and duct leakage control, variable frequency drives, blade path upgrades for steam turbines, redesign/replace economizer, and improved operating and maintenance practices. EPA did not propose any BSER for existing natural gas-fired turbines, finding that available emissions reductions would be expensive or would likely provide only small reductions.

The proposed rule gives states limited flexibility in making these determinations. They may consider remaining useful life of a unit, which may result in the application of a less stringent standard of performance or later compliance date; may accept non-BSER measures, but only if implemented at the unit itself; and may allow averaging among units at a single power plant, but not across plants. States would not be allowed to average or trade across affected units, nor between affected units and non-affected sources such as wind or solar generation. As such, the proposed rule would not allow consideration of emission reductions achievable through measures such as renewable energy, energy efficiency, increasing natural gas generation, retiring or reducing operation of coal units.

3. Affordable Clean Energy Rule as Finalized

On June 19, 2019, EPA published a final ACE rule. Because of its release so near the filing of this Resource Plan, we are still reviewing the rule and, to the extent there are substantive differences between the proposed and final rule that impact our Preferred Plan, we offer to supplement the record. However, we include a preliminary review here.

The ACE rule finalizes EPA's repeal of the CPP, which EPA maintains exceeded EPA's statutory authority because EPA took an overly expansive view of section 111(d) and endeavored to reduce emissions by shifting the balance of coal, gas and renewable generation across the power grid rather than focusing only on measures

implemented at the affected coal units.[5]

As in the proposed rule, EPA defines the BSER as only including measures implemented at the affected coal-fired units. The rule does not allow state plans to set carbon reduction targets based on renewable energy development, shifting from coal to gas, or averaging or trading across units – strategies the CPP relied on to drive the bulk of its emission reductions – but rather maintains the list of eight approved HRI measures states may consider in establishing unit-specific performance standards. It grants states discretion to determine which of those projects to require at the affected units and, following the statutory text, allows states to take into account the remaining useful life of the source and other factors, including the cost reasonableness of requiring HRI on units with a limited remaining useful life.

The final rule allows states three years from the date that it is published in the Federal Register to finalize plans and submit their own implementing rules. Compliance is then required two years thereafter, although states have discretion to extend that compliance deadline based on specific factors at the regulated units. Based on this timeline, we believe compliance could be required around 2024, not including possible delays due to litigation of the final rule.

4. Relevance to Xcel Energy

Xcel Energy submitted comments on the proposed ACE rule, arguing the Clean Air Act allows EPA to provide states much greater flexibility to reduce CO_2 through a range of actions throughout the electric system, and that granting such flexibility would result in more cost-effective and greater CO_2 reductions. However EPA retained its narrow, "inside the fence line" approach.

Under the rule as finalized – and absent our plans for early retirement of all remaining Upper Midwest coal units under the last Resource Plan and the current Preferred Plan – we expect that HRI could be required on coal-fired units that continue to operate. However, section 111(d)(1) explicitly requires, and EPA emphasizes, that EPA must "permit the State in applying a standard of performance to any particular source under a plan submitted under this paragraph to take into consideration, among other factors, the remaining useful life of the existing source to which such standard applies."[6] Further, the proposed rule specifies that consideration of remaining useful life would allow a state's plan to establish tailored compliance deadlines specific to each source; consider "changes in the operation of the units, among other factors the state believes

[5] EPA Fact Sheet, *Repeal of the Clean Power Plan*. June 19, 2019.
[6] ACE rule, 83 Fed. Reg. 44,749 (August 31, 2018).

are relevant";[7] consider "unreasonable cost of control resulting from plant age"; consider factors that "make application of a less stringent standard or final compliance time significantly more reasonable"; and consider "factors that influence decisions to invest in technologies to meet a potential performance standard [including] timing considerations like expected life of the source, payback period for investments, the timing of regulatory requirements, and other unit-specific criteria."[8]

The final rule also emphasizes this discretion:

> It will be up to the states to, either directly or indirectly, take cost into consideration in establishing unit-specific standards of performance. CAA section 111(d) explicitly allows the states to take into consideration, among other factors, the remaining useful life of the existing source in applying the standard of performance. For example, a state may find that an HRI technology is applicable for an affected coal-fired EGU but find that the costs are not reasonable when consideration is given to the timeframe for the planned retirement of the source (i.e., the source's remaining useful life).[9]

At this point, it is too early to predict exactly how Minnesota's ACE plan[10] will treat the units that the company is proposing to retire in our Preferred Plan. Minnesota's implementation of the ACE rule will depend on the outcome of inevitable litigation over the rule as well as the state plan development process, which will be in the hands of the Pollution Control Agency (PCA). Based on the factors set forth above, however, we believe that PCA could avoid requiring the installation of HRI on the company's coal units by incorporating the proposed unit retirement dates into the Minnesota ACE plan. Requiring HRI on units with only a few years of life remaining would necessitate a very short payback period, imposing accelerated depreciation of HRI investments and an unreasonable cost of control. We believe that, following the statutory language of Section 111(d)(1), EPA would be likely to approve such a plan. The company will continue to evaluate the implications of the ACE rule and work with PCA to harmonize the Minnesota ACE plan with the Preferred Plan in a manner that minimizes the cost of the ACE rule to customers.

B. Regulation of CO_2 from New, Modified and Reconstructed Power Plants

1. Standards of Performance for New, Modified and Reconstructed Stationary Sources

[7] 83 Fed. Reg. 44,763.
[8] 83 Fed. Reg. 44,766.
[9] EPA "Affordable Clean Energy" final rule, pre-publication version, at page 81. *Repeal of the Clean Power Plan; Emission Guidelines for Greenhouse Gas Emissions from Existing Electric Utility Generating Units; Revisions to Emission Guidelines Implementing Regulations*. June 19, 2019.
[10] We do not speak to ACE plans in the other Upper Midwest states served by Xcel Energy, since the Company has no coal units in North Dakota, South Dakota, Wisconsin or Michigan.

EPA in October 2015 promulgated, under Section 111(b) of the Clean Air Act, a final rule *Standards of Performance for Greenhouse Gas Emissions from New, Modified, and Reconstructed Stationary Sources: Electric Utility Generating Units*.[11] The rule applies to newly constructed, modified, and reconstructed fossil fuel-fired utility boilers and IGCC units, and newly constructed and reconstructed stationary combustion turbines. The trigger for applicability is that construction of the new unit began, or the modification or reconstruction took place, after January 2014. EPA defined the BSER for new fossil fuel-fired utility boilers as highly efficient supercritical pulverized coal with partial post-combustion carbon capture and storage (CCS), with an equivalent performance standard of 1,400 lbs CO_2/MWh gross. The BSER for natural gas-fired stationary combustion turbines operated in a "baseload" configuration is defined as use of efficient natural gas combined cycle technology, with a corresponding performance standard of 1,000 lbs CO_2/MWh gross, while natural gas-fired units (generally simple cycles) operated in a "non-baseload" configuration are given a performance standard of 120 lbs CO_2/MMBtu. Modified and reconstructed units in each category are given their own BSER definitions and corresponding performance standards.[12]

Numerous parties challenged the 2015 rule in the U.S. Court of Appeals for the D.C. Circuit, with the cases consolidated under *North Dakota v. EPA*. At EPA's request, the D.C. Circuit has held the consolidated cases in abeyance since April 2017, pending the Agency's review of the 2015 rule and any resulting rulemaking.

2. Proposed 2018 Replacement Rule

EPA in December 2018 released a proposed rule revising the 2015 section 111(b) rule discussed above. This rule, titled *Review of Standards of Performance for Greenhouse Gas Emissions from New, Modified, and Reconstructed Stationary Sources: Electric Utility Generating Units*,[13] revises the emissions standards for new, modified, and reconstructed fossil fuel-fired electric utility steam generating units. EPA proposes that BSER would not be partial CCS, based on EPA's updated assessment of capital costs of CCS, falling electricity demand, water availability, and limited geographic availability of sites suitable for sequestration. Instead, EPA proposes that BSER is the most efficient demonstrated steam cycle (e.g., supercritical steam conditions for large units, subcritical steam conditions for small units) in combination with best operating

[11] 80 *Fed. Reg.* 64,510, October 23, 2015.
[12] M.J. Bradley & Associates, August 14, 2015, *Summary of EPA's Final Standards of Performance for Greenhouse Gas Emissions from New, Modified, and Reconstructed Stationary Sources: Electric Utility Generating Units*. Available at https://www.mjbradley.com/sites/default/files/MJB&A%20Summary%20of%20Final%20GHG%20NSPS_Aug14.pdf
[13] 83 *Fed. Reg.* 65,424, December 20, 2018.

practices. EPA proposes a corresponding set of emission standards, ranging from 1,900 lbs CO_2/MWh gross for units with heat input >2,000 MMBtu/hr, to 2,000 lbs CO_2/MWh gross for units with heat input <2,000 MMBtu/hr, to 2,200 lbs CO_2/MWh gross for various other types of units and for modified and reconstructed units.

EPA does not propose revisions to the 2015 rule for stationary combustion turbines. EPA does solicit comment on whether the rule should make allowances for circumstances in which simple-cycle stationary combustion turbines may be called upon to operate in excess of the "non-baseload" threshold in the 2015 rule, e.g. due to high utilization to balance solar and wind generation, and whether such turbines should be given a separate subcategory and standard of performance.

Finally, EPA proposes to retain its original "endangerment" finding as the basis for regulating CO_2 emissions from fossil fuel-fired EGUs, but takes comment on whether it is correct to interpret this finding as a finding made only once for each source category, or whether EPA must make a new endangerment finding each time it regulates an additional pollutant by an already-listed source category. EPA also solicits comment on whether there is a rational basis for declining to regulate CO_2 emissions from new coal-fired units in light of ongoing and projected reductions in power sector CO_2 emissions. The 111(b) revision remains a proposed rule as of this writing.

3. Relevance to Xcel Energy

Xcel Energy commented on the 2015 rule, indicating we did not agree CCS is an appropriate BSER because it was not adequately demonstrated and was not at the time deployed on any commercially operating power plant in the United States. Since that time CCS has been deployed on a small number of commercial units, but remains far from widespread. We believe CCS on *gas* units may become viable in the future, and is one of several potential carbon-free dispatchable technologies that could help achieve our 2050 aspiration of 100% carbon-free electricity. However, Xcel Energy does not have plans to build a new coal-fired power plant, with or without CCS, so the rule's requirements for new coal units have no impact on the Company.

We believe any new natural gas combined cycle unit we may construct would be able to meet the 2015 rule's performance standard of 1,000 lbs CO_2/MWh gross. It is possible that new simple-cycle stationary combustion turbines we build[14] could be called upon to operate in excess of the non-baseload thresholds in the 2015 rule, and

[14] Note that under the Preferred Plan, our modeling calls for no new gas combustion turbines until 2031, and even at that time, gas combustion turbines could be replaced by other resources that meet the same firm peaking need.

could struggle to achieve the 120 lbs CO_2/MMBtu performance standard applicable to such units. Since these units would likely operate this much only because they are supporting integration of higher amounts of renewables, we believe it may be appropriate for EPA to relax the non-baseload threshold or create a separate subcategory and standard of performance for such units. EPA's decision on simple-cycle aeroderivative turbines will become known when EPA finalizes the 111(b) rule.

C. Progress on the State of Minnesota's Greenhouse Gas Goals

The Next Generation Energy Act (NGEA) of 2007 states that:

> It is the goal of the state to reduce statewide greenhouse gas emissions across all sectors producing those emissions to a level at least 15 percent below 2005 levels by 2015, to a level at least 30 percent below 2005 levels by 2025, and to a level at least 80 percent below 2005 levels by 2050.[15]

These goals apply to all economic sectors; the NGEA does not provide goals specific to electricity or other sectors, or to individual companies. The Minnesota Pollution Control Agency (PCA) maintains the state's GHG inventory, publishes data,[16] and provides a biennial report to the Legislature on progress on the NGEA goals.[17]

1. Xcel Energy's CO_2 Inventory and Reporting Methods

Xcel Energy supports timely, transparent public reporting of CO_2 and other greenhouse gas emissions. Our comprehensive GHG reporting is based on The Climate Registry[18] and its *Electric Power Sector Protocol*, which aligns with the World Resources Institute and ISO 14000 series standards. Our company joined The Climate Registry as a founding member in 2007 to help establish a consistent and transparent standard for calculating, verifying and reporting greenhouse gases. Through The Climate Registry, we annually third-party verify, register and publicly disclose our greenhouse gas emissions. We have reported and verified emissions for 2005 through 2017, with verification of 2018 emissions pending. This reporting – which differs in a few respects from PCA's methodology for the state – takes the following approach:

- CO_2 emissions are reported from all owned power plants and purchased power across our Upper Midwest integrated system, serving five states. This is a broader boundary than PCA's method, which considers emissions from power plants within Minnesota and estimates emissions from power imported into

[15] Minn. Stat. §216H.02, subd. 1.
[16] See https://www.pca.state.mn.us/air/greenhouse-gas-emissions-data.
[17] See https://www.pca.state.mn.us/air/state-and-regional-initiatives.
[18] See https://www.theclimateregistry.org.

Minnesota.

- It includes CO_2 from owned fossil fuel-fired power plants, purchased power agreements (PPAs), and power purchased in the wholesale markets. The majority of these emissions (over 80 percent) are directly measured using Continuous Emissions Monitoring Systems (CEMS); a small portion (less than 10 percent) are from PPAs with counterparties whose emission rate is known because they report emissions to EPA, the Energy Information Administration or Federal Energy Regulatory Commission; a still smaller portion (less than 5 percent) are from counterparties who do not have a defined PPA with Xcel Energy and so are assigned a regional grid average emission rate.
- Reported emissions from power generation include CO_2 only, not methane and nitrous oxide. However, methane and nitrous oxide add less than ½ of one percent to our total CO_2-equivalent emissions, even after accounting for the greater global warming potentials of these gases.
- We report CO_2 from electricity provided to our customers. Xcel Energy sells a small portion of the electricity we generate and purchase as short-term sales into the wholesale market. CO_2 from these sales is excluded from our reporting, because the energy does not serve our customers, and it is likely that many companies purchasing the energy account for the emissions in their reporting, so including them in our reporting could result in double counting.

2. State Goal for 2015

PCA's statewide GHG inventory data now covers 2005 through 2016. Statewide GHG emissions declined about 5 percent from 2005 to 2015, missing the statewide goal of 15 percent. Statewide emissions declined more in 2016 – reaching 12 percent below 2005 by the end of that year – however performance varied by sector: electric sector emissions declined 29 percent, transportation emissions 8 percent, agriculture, forestry and land use emissions 12 percent, and waste emissions 6 percent, while emissions in the residential, commercial and industrial sectors all increased.[19]

Thus while the state overall and individual sectors have fallen short of the NGEA goals, the electric sector has approximately doubled the targeted reduction. According to PCA,

> Emissions from electricity used by Minnesotans are down by about 29% since 2005. This means the electricity generation sector has met the Act's 2015 goal, and has nearly

[19] See https://www.pca.state.mn.us/air/greenhouse-gas-emissions-data, as well as PCA's January 2019 report, *Greenhouse gas emissions in Minnesota: 1990-2016: Biennial report to the Legislature tracking the state's contribution to emissions contributing to climate change*, pages 5-6, available at https://www.pca.state.mn.us/sites/default/files/lraq-2sy19.pdf.

> reached the 2025 emissions reduction goal. Moreover, Minnesota's utilities have committed to additional coal plant closures that will further reduce GHG emissions from this sector in the future. Transportation is now the largest source of GHG emissions in Minnesota. This sector will require ongoing, focused effort to reduce emissions to the levels necessary to meet statutory goals.[20]

Xcel Energy's Upper Midwest CO_2 emissions have declined by even more. We provide below our emission reductions to date for three relevant years: 2015, for comparison to the NGEA goal for that year; 2016, for comparison to PCA's statewide data; and 2018, our latest emissions data available. Note that the 2018 data is not yet third-party verified.

Table 1: Xcel Energy Upper Midwest CO_2 Emission Reductions

Year	Total CO_2 from electricity serving customers (million short tons)	Reduction from 2005	Comparison
2015	21.1	25 percent	Exceeding state goal of 15 percent by 2015
2016	19.0	32 percent	More than double state goal for 2015 and exceeding state goal for 2025
2018	18.5	34 percent	More than double state goal for 2015 and exceeding state goal for 2025

3. State Goal for 2025

Under the Preferred Plan, Xcel Energy's Upper Midwest CO_2 emissions are on track for an approximately 60 percent reduction by 2025, doubling the NGEA statewide goal for that year. These reductions reflect our full 1,850 MW wind portfolio being online by that time, significant growth of solar, continued energy efficiency program achievements, continued operation of our carbon-free nuclear units, and retirement of one Sherco unit in 2023 (with the other two units at Sherco and the A.S. King unit retiring by 2030).

4. State goal for 2050

A true transformation has occurred in the electric sector since our last Resource Plan. In that plan, we discussed the state's 80 percent by 2050 goal qualitatively, but identified many technical and economic barriers to creating a Upper Midwest system that serves our customers' electricity needs affordably and reliably with only 20 percent of the CO_2 emissions of 2005. Today, only four years later, Xcel Energy has

[20] *Greenhouse gas emissions in Minnesota: 1990-2016*, page 2.

set a company-wide goal of an 80 percent reduction in CO_2 emissions *by 2030* – i.e. achieving the State's economy-wide goal, twenty years ahead of time. Moreover, we believe we can achieve this reduction cost-effectively, with our expected fleet transition and operational changes and with the renewable, carbon-free generation and energy storage technologies available today. Our 80 percent by 2030 goal is for all eight states Xcel Energy serves; under the Preferred Plan, our Upper Midwest system will achieve about an 84 percent reduction. And our aspiration for 2050 is 100 percent carbon-free electricity for our customers.

In announcing these goals, we stressed that they are not Resource Plans. Our Preferred Plan represents a concrete down payment on those Xcel Energy-wide goals – moving our Upper Midwest system beyond 80 percent reduction by 2030 and putting us on a trajectory to removing carbon from our customers' electricity entirely by 2050. We also made clear that our 2050 aspiration requires technologies not yet commercially available at the scale needed. This cannot be done with only wind, solar, and the short-duration battery storage technologies available today. It will likely require some amount of carbon-free dispatchable generation, longer-duration storage than is available today, more electrification, and more flexible demand. The technologies needed may include gas with carbon capture and storage, power to gas (renewable hydrogen), seasonal energy storage, advanced nuclear or small modular reactors, deep rock geothermal, and other technologies yet to be identified. Each of these options holds promise, but they will require further research, development, demonstration and deployment to become viable solutions at the cost and scale needed. Coupled with supportive federal and state policies, utility Resource Plans can send signals to the market around price, capabilities and timing for when these technologies will be needed.

In sum, we believe the state's goal of 80 percent reduction by 2050 is attainable and affordable within the electric sector, and that even 100 percent carbon-free electricity by 2050 is achievable with sufficient investment in new technology. That said, getting the last 20 percent of carbon out of the electric system is technically challenging and could face steeply increasing costs. This is especially the case if we limit the portfolio to two or three technologies – e.g., wind, solar and short-term storage – rather than creating a balanced portfolio of technologies for an affordable, reliable, and carbon-free system in 2050.

D. Recent Federal and State Legislation

No new state or federal legislation mandating a reduction in GHG emissions from Xcel Energy's system has passed as of filing this plan. However, some legislation has been proposed, which may indicate the potential shape of energy/climate policy in

coming years. We summarize here some of those proposals.

1. Green New Deal

In February 2019, Rep. Ocasio-Cortez (D-NY) and Sen. Markey (D-MA) introduced H. Res. 109 and S. Res. 59, formalizing one version of the "Green New Deal" (GND) concept of an aggressive mobilization to address climate change combined with nationwide job creation, modeled on the Depression-era programs of the Roosevelt Administration. The resolutions cite recent United Nations and U.S. Government reports on climate risks and propose that, in order to keep global temperature increase below 1.5 degrees Celsius, GHG emissions must be reduced 40-60 percent by 2030 from 2010 levels and reach net-zero global emissions by 2050. The resolutions point to the impacts of climate change in exacerbating systemic injustices and disproportionately impacting certain vulnerable communities, as well as the threat posed to national security, and call for ambitious progressive policies aimed at resolving social injustice as part of the transition.

The resolutions propose it is the duty of the Federal Government to create a GND that would achieve net-zero GHG emissions through a fair and just transition for all communities and workers; create millions of good, high-wage jobs and ensure prosperity and economic security for all; invest in infrastructure and industry to sustainably meet the challenges of the 21st century; secure for future generations clean air and water, climate and community resiliency, healthy food, access to nature, and a sustainable environment; and promote justice and equity by stopping current, preventing future, and repairing historic oppression of indigenous peoples, communities of color, migrant communities, deindustrialized communities, depopulated rural communities, the poor, low-income workers, women, the elderly, the unhoused, people with disabilities, and youth.[21]

To achieve these goals, the resolutions call for a ten-year national mobilization focusing on 1) building resiliency against the impacts of climate change, such as extreme weather; 2) repairing and upgrading infrastructure; 3) meeting 100% of the power demand through clean, renewable, and zero-emission energy sources; 4) building or upgrading energy efficient distributed and "smart" power grids; 5) upgrading all existing buildings for maximum resource efficiency (energy, water) and safety, including through electrification; 6) spurring growth in clean manufacturing; 7) working with farmers and ranchers on sustainable farming and decarbonization of the agricultural sector; 8) development of zero-emission vehicle infrastructure and manufacturing and more public transit/rail; 9) funding for communities with

[21] See https://www.congress.gov/bill/116th-congress/house-resolution/109/text.

pollution related health problems; 10) removing GHG from the atmosphere through proven low-tech solutions such as land preservation and afforestation; 11) restoring threatened and endangered ecosystems; 12) cleaning up hazardous waste sites; 13) eliminating sources of pollution; and 14) promoting international exchange of technologies and expertise on climate.[22]

Notably different from earlier GND proposals, the resolutions do not call for 100 percent renewable energy, but instead a transition to clean, zero-carbon energy, leaving open possibilities non-renewable but zero-carbon sources. They do not call for a carbon price, since at least some of the groups supporting the GND do not favor a carbon tax or cap-and-trade.

Since these GND resolutions are high-level statements of goals and principles for federal programs, rather than specific compliance mandates for electric utilities, we cannot directly evaluate this Resource Plan in relation to them. We note that this Resource Plan appears generally consistent with the resolutions in that it would:

- Reduce Xcel Energy's Upper Midwest emissions 80 percent by 2030, as compared to the GND goal of 50-60 percent;
- Put Xcel Energy on a path to 100 percent carbon-free electricity for our customers by 2050, more ambitious than the GND net-zero goal;
- Prioritize a fair and just transition by working to create new jobs and economic opportunities in the communities hosting retiring power plants, while also creating new employment in building and operating clean energy resources added to our system;
- Focus on reducing conventional pollution and expanding clean energy access for all;
- Improve the resiliency of our electric system and communities;
- Upgrade energy infrastructure and invest in a smarter energy grid, energy efficiency, and electrification of transportation and other end uses.

2. *Clean Energy Standard Act of 2019*

Senators Tina Smith (D-MN) and Ben Ray Luján (D-NM) in May 2019 introduced S. 1359, the *Clean Energy Standard Act of 2019*. This bill, which the authors describe as a path to net-zero emissions in the electric sector by midcentury, would establish a federal clean energy standard (CES) requiring retail electric suppliers to provide an

[22] https://www.congress.gov/bill/116th-congress/house-resolution/109/text.

increasing share each year of the electricity serving their customers from "clean energy" resources, defined to include renewables, qualified renewable biomass, hydroelectricity, nuclear, qualified waste-to-energy, qualified low carbon fuels, qualified combined heat and power, qualified energy storage, dispatchable low- and zero-emission technologies, and carbon capture, storage and utilization. The approach is modeled on state renewable energy standards, but broader since in addition to renewables it allows low- and zero-carbon resources to qualify.

The bill requires retail electricity suppliers with more than 60 percent clean energy today to increase their clean energy percentage (as a share of retail sales plus behind the meter generation) at 1.75 percent per year, while retail electricity suppliers with less than 60 percent today must increase at 2.75 percent per year. Retail electricity suppliers comply with the CES by adding clean energy resources to their fleet, purchasing federal clean energy credits from other retail electricity suppliers, or paying an alternate compliance payment initially set at 3 cents per kWh. Recognizing the need for 24/7 low- and zero-carbon technologies in addition to variable renewables, the bill provides innovation multipliers for dispatchable low-emission and dispatchable zero-emission technologies. It also establishes a new clean energy research, development, demonstration and deployment program within the US Department of Energy.

We believe the Company is well positioned to comply with the CES as introduced. Under our Preferred Plan, the Company would have greater than 60 percent qualifying clean energy from 2019 on, so be required to increase at the slower 1.75 percent per year rate; by 2023, the Company's clean energy percentage would exceed the 90 percent ceiling at which retail electricity suppliers are no longer required to increase until 2040. Due to planned renewable additions, maintenance of our nuclear units, and the proposed relicensing of Monticello, our modeling shows the Company in excess of its compliance obligation throughout the planning period of 2020 to 2034.

3. Walz/Flanagan Clean Energy Plan

In March 2019 Minnesota Gov. Walz and Lt. Gov. Flanagan proposed a "One Minnesota Path to Clean Energy," a set of three policy proposals designed to achieve 100 percent clean energy in the state's electricity sector by 2050. The three components are:

- *100 Percent Clean Energy by 2050*. This standard would require all electric utilities in Minnesota to use only carbon-free energy resources by 2050, while allowing each utility the flexibility to choose how and at what pace they meet the standard. The proposal includes provisions to assist workers and communities

affected by the transition, while prioritizing local jobs and prevailing wages for large new clean energy projects.

- *Clean Energy First*. This regulatory policy would require that, whenever a utility proposes to replace or add new power generation, it must prioritize energy efficiency and clean energy resources over fossil fuels. This policy would strengthen an existing renewable energy preference in Minnesota law, and it would allow for fossil fuel-based power only if needed to ensure reliable, affordable electricity.
- *Energy Optimization*. This proposal would raise Minnesota's Energy Efficiency Resource Standard for investor-owned electric utilities and expand the Conservation Improvement Program that helps Minnesota households and businesses save on their utility bills by using energy more efficiently. It would also encourage utilities to develop innovative new programs to help consumers and businesses switch to more efficient, cleaner energy. In addition, it would target more energy-saving assistance for low-income households."[23]

To carry out this proposal, the Administration worked with legislators to introduce HF1956, which included all three components above, and SF1456, which included only the Clean Energy First preference. The bills were incorporated into the respective House and Senate omnibus legislation. Ultimately, none of this package of bills passed the Minnesota Legislature in 2019, but they provide an indication of the potential direction of clean energy policy in Minnesota in the coming years. We believe the Preferred Plan positions the Company well to comply with these policies.

II. CONVENTIONAL POLLUTANTS

This section discusses requirements that may apply to emissions of pollutants that are regulated under four primary Clean Air Act (CAA) programs: National Ambient Air Quality Standards (NAAQS), a CAA program that addresses interstate transport of air pollution, CAA programs that address visibility impairment in national parks and wilderness areas, and a CAA program that addresses emissions of hazardous air pollutants. Each program is addressed in turn.

A. National Ambient Air Quality Standards

The CAA requires the EPA to set NAAQS to protect public health and the environment. NAAQS include both (1) primary standards to protect public health, including the health of sensitive populations, such as asthmatics, children and the

[23] See https://mn.gov/governor/news/?id=1055-374280.

elderly and (2) secondary standards to protect public welfare, including protection against damages to animals, crops and buildings. The EPA has established NAAQS for six pollutants: particulate matter (PM), nitrogen oxides (NO_x), sulfur dioxide (SO_2), ozone, carbon monoxide (CO), and lead (Pb). The NAAQS program has been in place since the early 1970s. The EPA is required to review the NAAQS every five years and revise them as appropriate to protect public health and welfare.

Once EPA adopts or revises a NAAQS, states have two years to monitor their air, analyze the data and submit to EPA their recommended classification of the state into Attainment areas (areas having monitored ambient air quality concentrations below the NAAQS), Nonattainment areas (areas having monitored ambient air quality concentrations above the NAAQS), and Unclassifiable areas. The EPA reviews the state's submittal and determines the final area designations a year later. When the EPA designates an area as Nonattainment, the state is given up to three years to develop a new State Implementation Plan (SIP) which identifies actions to be taken to bring the area back into Attainment. A SIP must include emission reduction requirements needed to demonstrate that air quality will attain the NAAQS in the timelines required by the CAA – usually within two to seven years after the SIP is submitted to the EPA for approval.

Recent revisions to all six NAAQS were finalized within the last few years to reflect the latest scientific information about the health effects of these air pollutants. Despite several NAAQS being significantly tightened, there are at present no Nonattainment areas in the state of Minnesota that might result in SIP emission reduction requirements being imposed on Xcel Energy's Upper Midwest power plants. The following table summarizes the current status of the NAAQS Attainment in Minnesota:

Table 2: Xcel Energy Upper Midwest System Status – NAAQS Attainment

Pollutant	Date Reviewed[24]	System Status[25]	Date Designated	Next Review[26]
PM	2012	Attainment	2015[27]	2020
O_3	2015	Attainment	2017[28]	2020
SO_2	2019	Attainment	2018[29]	2024
NO_x	2018	Attainment	2012[30]	2023
CO	2011	Attainment/Maintenance[31]		TBD[32]
Pb	2016	Attainment	2011[33]	2021

Our remaining coal plants are all equipped with scrubbers to control SO_2 emissions as well as air pollution control equipment to control PM emissions. All three Sherco units are equipped with NOx combustion controls that have significantly reduced NO_x emissions from the units. The King plant and our combined cycle gas plants are also equipped with Selective Catalytic Reduction (SCR) technology to control NO_x emissions.

With the planned retirement of Sherco Units 1 and 2, the only additional control equipment that could be required would be SCR technology to further reduce NO_x emissions from Sherco Unit 3. Depending on the date of required compliance, any need to install an SCR to address a NAAQS would either need to be completed by the attainment date or the unit would need to shut down by the attainment date. With the proposed 2030 retirement of Sherco 3, we believe unit retirement may be acceptable in lieu of SCR. Additionally, a full analysis may render the controls not cost-effective

[24] This column reflects the last time each NAAQS was reviewed. Note that in the case of the most recent reviews of the NAAQS for SO_2, NOx, CO and Pb, EPA did not change the level of the NAAQS, so there was no need to initiate a new designation and planning process for those standards.
[25] This column reflects the designation of areas for locations where Xcel Energy's Upper Midwest coal or natural gas plants are located.
[26] This column reflects the date of EPA's announced plans to review a NAAQS, application of the five year CAA deadline for NAAQS reviews, or "TBD" if the five year deadline has passed and there is no announced plan to complete the next NAAQS review.
[27] *See* 80 Fed. Reg. 2206, 2247-48 (Jan. 15, 2015).
[28] *See* 82 Fed. Reg. 54232, 54255-56 (Nov. 16, 2017).
[29] *See* 83 Fed. Reg. 1098, 1134-36 (Jan. 9, 2018).
[30] *See* 77 Fed. Reg. 9532, 9562 (Feb. 17, 2012).
[31] As of 2010, there were no areas of the country in Nonattainment of the CO standard. Areas formerly Nonattainment have all been designated "maintenance" areas, which are subject to certain CAA requirements for two ten-year maintenance periods after achieving compliance with the standards to assure continued attainment. https://www.epa.gov/co-pollution/applying-or-implementing-outdoor-air-carbon-monoxide-co-standards#designations The Minneapolis/St. Paul Metropolitan Area is a maintenance area for CO. https://www3.epa.gov/airquality/greenbook/cbcs.html#MN
[32] Because the last review in 2011 retained the original NAAQS adopted in 1971, we do not expect this standard to change in the future.
[33] *See* 76 Fed. Reg. 72097, 72111 (Nov. 22, 2011), which designated all of Minnesota as attaining the standard, except a portion of Dakota County.

based on the reductions to be achieved.

In addition, if future further emission reductions are needed, it is possible that the state would evaluate whether any upgrades are available to existing controls to further reduce air emissions.[34] Based on the timeline for the next NAAQS reviews shown above, if a standard is made more stringent in the future, and if Minnesota does not meet that standard in areas where our plants operate, further emission reductions might be considered at Xcel Energy's Upper Midwest coal and natural gas plants in the mid to late 2020s.

B. Interstate Transport of Air Pollution

The CAA also requires that NAAQS SIPs include provisions that prevent sources within a state "from emitting any air pollutant in amounts which will … contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to any" NAAQS.[35] The EPA has developed programs for the Eastern U.S. that would reduce interstate transport of pollutants emitted by Electric Generating Units (EGUs) that are precursors to ozone and fine particles. NO_x is a precursor to ozone and fine particle formation, while SO_2 is a precursor to fine particle formation.

The Cross-State Air Pollution Rule (CSAPR) was designed as a "cap-and-trade" program that reduces overall emissions from EGUs. This means that total emissions from EGUs in a state or region are limited (the cap), and each ton of emissions allowed is represented by an emission allowance that can be transferred among EGUs (the trade). A cap-and-trade program thus reduces total emissions to the capped amount, but provides flexibility for EGUs to meet their individual emission reduction requirements through installation of control equipment, purchase of emission allowances from other EGUs, or a combination of both.

Depending on EPA's analysis of an upwind state's contribution to Nonattainment in downwind states, CSAPR imposes one or both of the following emission limitations: (1) summer season NO_x emissions (to address ozone), and/or (2) annual NO_x and SO_2 emissions (to address fine particles). In Minnesota's case, the impact of concern has been fine particle Nonattainment areas in downwind states, rather than ozone. The CSAPR has applied since 2015 to Minnesota for fine particle precursors and to Wisconsin for fine particle precursors and ozone. NSP-Minnesota holds sufficient emission allowances to meet CSAPR requirements, while NSP-Wisconsin has

[34] In general, upgrades to existing pollution control technology are far less expensive than installation of an entirely new retrofit control system.
[35] CAA, 42 U.S.C. section 7410(a) (2)(D)(i)(I).

complied through operational changes and some allowance purchases.

EPA has considered further revisions to the CSAPR program as may be needed to address the 2008 ozone NAAQS and the 2012 particle NAAQS. EPA decided that further reductions through CSAPR are not needed to address the 2012 particle NAAQS,[36] and recently decided that further reductions from current emission levels are not needed to address the 2008 ozone NAAQS.[37] It is not known whether or when EPA might consider further emission reductions as part of implementing the 2015 ozone NAAQS.[38]

C. Visibility Impairment in National Parks and Wilderness Areas

Visibility impairment is caused when sunlight encounters pollution particles in the air. Some light is absorbed and other light is scattered before it reaches an observer, reducing the clarity and color of what the observer sees. The CAA established a national goal of remedying existing and preventing future visibility impairment from man-made air pollution in specified "Class I" areas – national parks and wilderness areas throughout the United States, including the Boundary Waters Canoe Area and Voyageurs National Park in Minnesota. The visibility programs focus on reducing emissions of PM, SO_2 and NO_x as pollutants that can result in visibility impairment from EGUs.

The EPA has taken a two-step approach to implement the visibility program. The first step, "reasonably attributable visibility impairment" (RAVI), was implemented in the 1980s to address visibility impairment reasonably attributable to a specific source. The EPA adopted regulations for this program designed to address RAVI, defined as "visibility impairment that is caused by the emission of air pollutants from one, or a small number of sources."[39]

The second step was designed to address widespread, regionally homogeneous haze

[36] On March 17, 2016, EPA issued guidance for states to analyze interstate pollution impacts and, if needed, to develop plans to address those impacts. EPA stated that few areas would have problems meeting the 2012 particle NAAQS, and plans to address any need for upwind reductions on a case-by-case basis. *Information on the Interstate Transport "Good Neighbor" Provision for the 2012 Fine Particulate Matter National Ambient Air Quality Standards under Clean Air Act Section 110(a)(2)(D)(i)(I),* Office of Air Quality Planning and Standards, at 3.
[37] *See* 83 Fed. Reg. 65878 (Dec. 21, 2018).
[38] On March 27, 2018, EPA issued guidance for states to design their own plans to address interstate air pollution impacts as part of their SIPs under the 2015 ozone NAAQS. https://www.epa.gov/airmarkets/memo-and-supplemental-information-regarding-interstate-transport-sips-2015-ozone-naaqs If in the future states submit plans that EPA does not approve on this issue, EPA could consider developing its own plan at some future date.
[39] 40 C.F.R. section 51.301. Following an allegation that the Sherco plant might have a RAVI-type of impact, NSP-Minnesota entered into a settlement agreement that agreed to tighten SO2 emission limits on all three Sherco units to resolve the allegation. The new limits have been implemented at the Sherco plant. *See* 40 C.F.R. section 52.1236(e), adopted on March 7, 2016 (81 Fed. Reg. 11668).

that results from emissions from a multitude of sources. In 1999, the EPA adopted its Regional Haze Rule (RHR) to address this type of visibility impairment. State environmental agencies are required to submit SIPs that develop and implement their strategy to reduce emissions that may contribute to regional haze. RHR SIPs also must include reasonable progress goals and periodic evaluation/revision cycles designed to make appropriate progress toward the national goal of no human-caused visibility impairment in Class I areas by 2064. These SIPs must be revised approximately every ten years to continue making reasonable progress toward reaching the 2064 national goal.

The Minnesota Pollution Control Agency (PCA) developed, and EPA approved, Minnesota's regional haze plan for EGUs for the first ten-year planning period of the program. The PCA's plan for Sherco Units 1 and 2 required combustion controls to reduce NO_x (Over-Fire Air (OFA), combustion controls and Low- NO_x burners) and scrubber upgrades to reduce SO_2. These controls have been installed and are in operation to reduce emissions from these units.

The PCA will also be required to revise its SIP by 2021 to consider additional emission reductions that may be necessary to continue to make reasonable progress during the next ten year planning period toward achievement of the national visibility goal by 2064.

Our system is equipped with almost all of the pollution control equipment that could be required in future regional haze planning cycles. With the planned retirement of Sherco Units 1 and 2, the only additional control equipment that could be required would be SCR technology to further reduce NOx emissions from Sherco Unit 3. Depending on the date of required compliance, any need to install an SCR to address Regional Haze compliance would depend on unit retirement dates. The Regional Haze program provides some flexibility to agree to a unit retirement some years later than an SCR might otherwise be required, because of the long-term nature of this program. With the proposed 2030 retirement of Sherco 3, we believe unit retirement may be acceptable in lieu of SCR. Additionally, a full analysis may render the controls not cost-effective based on the reductions to be achieved.

In addition, if future further emission reductions are needed, it is possible that the state would evaluate whether any upgrades are available to existing controls to further reduce air emissions. Our remaining coal plants all have scrubbers installed to control SO_2 emissions and have air pollution control equipment to control PM emissions. All three Sherco units are equipped with NO_x combustion controls that have significantly reduced NOx emissions from the units. The King plant and our combined cycle gas plants are also equipped with SCR technology to control NO_x emissions.

D. Regulation of Hazardous Air Pollutant Emissions

Both state and federal regulations require reductions in Hazardous Air Pollutant (HAP) emissions from power plants. In 2006, the Minnesota Legislature passed the Minnesota Mercury Emissions Reduction Act (MMERA). The MMERA provided a process for implementation and cost recovery for utility efforts to reduce mercury emissions at certain power plants, in our case the King and Sherco generating facilities. In 2012, the EPA adopted its final rule establishing National Emission Standards for HAPs from coal- and oil-fired power plants. This rule is often referred to as the Mercury and Air Toxics Standard (MATS), and compliance was required by 2015. Mercury controls have already been installed and are operational on all three Sherco units and at King.[40]

The MATS also set emission limits for acid gases and non-mercury metals. PM is a surrogate for non-mercury metal emissions and SO_2 is a surrogate for acid gas emissions. The Sherco and King plants meet these standards using control technologies and through operational practices.

In 2011, the EPA adopted emission limits for HAPs from industrial boilers to regulate boilers and process heaters fueled with coal, biomass and liquid fuels. These standards apply to biomass combustion at Bay Front Units 1 and 2 as well as to several small heating boilers located at our facilities. Compliance was required by early 2016.

III. WATER

A. Cooling Water Intake Structures

Section 316(b) of the federal Clean Water Act (CWA) requires the EPA to develop regulations governing the design, maintenance and operation of cooling water intake structures to assure that these structures reflect the best technology available for minimizing adverse impacts to aquatic species. The regulations must address both impingement (the trapping of aquatic biota against plant intake screens) and entrainment (the protection of small aquatic organisms that pass through the intake screens into the plant cooling systems).

[40] The CAA requires that EPA review standards such as MATS each eight years to determine if control technology has improved and if the residual emissions left after compliance with the MATS pose additional residual risk to the public. EPA recently proposed to find that, based on its review, no revisions to the MATS are required. 84 Fed. Reg. 2670 (Feb. 7, 2019).

The EPA released a 316(b) rule on May 19, 2014, along with a Biological Opinion issued by the U.S. Fish and Wildlife Service (FWS) and National Marine Fisheries Service (NMFS), and published the final rule in August 2014. The rule requires companies:

- To adopt one of seven options addressing impingement of biota at the entrance to cooling water intake structures, with approval by state or federal National Pollutant Discharge Elimination System (NPDES) permit writers;
- To minimize entrainment of biota into the structures, as directed by the permit writer taking a number of factors into account;
- To implement the impingement, entrainment, and other measures as soon as practicable after the entrainment measures have been identified, with interim milestones the permit writer may set, or for new units upon commencing operations;
- To provide extensive information in permit applications, including source water physical and biological data, intake structure and system data, proposed impingement compliance methods and supporting study plans, previously conducted entrainment studies, and the operational status of the plants; and
- For plants that withdraw more than 125 million gallons per day, to provide two-year comprehensive entrainment characterization studies, technical feasibility and cost evaluation studies, benefit valuation studies, and studies of non-water quality environmental and other impacts, with peer review of the last three.

The rule does not mandate the use of closed-cycle cooling for existing facilities. However qualifying closed-cycle systems will satisfy the final rule's impingement and likely will satisfy its entrainment requirements. The definition of qualified closed-cycle cooling has been broadened to include existing impoundments of waters of the U.S., if sufficiently documented as having been designed to provide a recirculating cooling function or if built in uplands, and to delete references to specific cycles of concentration, percentage flow reduction, and continuous flow constraints.

Regarding Endangered Species Act (ESA) provisions, the final rule requires permit writers to provide copies of applications to the FWS and NMFS, so these agencies can provide input within 60 days on endangered and threatened species and critical habitat potentially affected by intake structures and recommended permit conditions. If permit writers incorporate those conditions and permittees conduct all measures recommended by the Services, the permit will provide "incidental take" authorization. The FWS/NMFS biological opinion provided with the final rule states that the final

rule is not likely to jeopardize listed species or destroy or adversely modify designated critical habitat.

The definition of "existing facilities" would include nuclear uprates and other repowered and significantly modified units, even if the turbine, condenser, or fuel are replaced. However, replacement units—essentially newly built, stand-alone units constructed at existing facilities regardless of change in generation capacity, cooling water flow, or use of an existing intake structure—would be considered a "new" unit and subject to closed-cycle cooling equivalent requirements.

The final rule provides a *de minimis* exception for impingement mortality requirements for very low impingement rates, but cautions that ESA-listed species may not be taken. The rule also provides less stringent impingement standards for low-capacity utilization units.

Upper Midwest system power plants that use greater than 2 million gallons per day of surface water are required to comply with the rule. This includes Sherco, Monticello, Riverside, High Bridge, Black Dog, King, Prairie Island, Red Wing, Wilmarth, Bay Front and French Island. Additionally, three plants may be required to reduce entrainment mortality: Monticello, King and Black Dog. The Sherco plant is already a closed-cycle cooling facility and as such, will not likely be required to make significant cooling water intake structure upgrades to comply with the rule.

B. Thermal Discharge

The EPA regulates the impacts of heated cooling water discharge from power plants under CWA Section 316(a). States with authority to implement and enforce CWA programs (e.g. Minnesota, Wisconsin) have state-specific water quality criteria including thermal discharge temperature parameters to protect aquatic biota. Plants must operate in compliance with the thermal discharge temperature parameters. No changes have been made to the thermal discharge temperature parameters in Minnesota. In 2010, Wisconsin implemented new water quality standards regulating the thermal discharge temperature from facilities with state-issued NPDES permits. The new requirements are being incorporated into facility permits as the permits come due for renewal.

Our Bay Front plant in northern Wisconsin was the first Xcel Energy plant to receive new thermal discharge limits, in 2012. Preliminary modeling of the plant discharge indicated that there could challenges to meeting the new requirements. Field monitoring of the discharge showed that the plant was complying with the new thermal discharge limits during normal operations.

French Island does not currently have to comply with the thermal rules. Preliminary evaluation indicates that French Island will have challenges to achieve compliance during the late summer and early fall periods of the year. The existing permit issued in 2018 requires a thermal monitoring plan (due 2020) with monitoring (due 2021). Monitoring data are due with permit application submittal (September 2022). Negotiations with the Wisconsin Department of Natural Resources during permit reissuance will determine what, if any, thermal limits are required.

C. Effluent Limitation Guidelines

As part of the NPDES process, the EPA identifies technology-based contaminant reduction requirements called Effluent Limitation Guidelines (ELGs). The ELGs are used by permit writers as the maximum amount of a pollutant that may be discharged to a water body and apply to power plants that use coal, natural gas, oil or nuclear materials as fuel and discharge treated effluent to surface waters, as well as to utility-owned landfills that receive coal combustion residuals. ELGs are periodically updated to reflect improvements in pollution control and reduction technologies.

The EPA revised the ELG rule on September 30, 2015 with two implementation deadlines. Impacted facilities are required to comply with the new requirements between 2018 and 2023. September 2017, EPA issued a rule postponing certain compliance dates of the 2015 ELG rule while EPA reconsiders portions of the rule. Specifically, EPA delayed the "no earlier than" compliance date so that facilities could not be compelled to comply with rule. EPA plans to issue a revised rule before the 2023 compliance due date and may propose a new compliance timeline.

EPA's 2015 final rule updated the ELGs for flue gas desulfurization systems (FGD), bottom ash transport water (BATW), flue gas mercury control systems (FGMC) and fly ash transport water (FATW) that discharge to surface waters. The final rule addressed discharges directly to surface waters and indirectly to surface waters via municipal wastewater treatment plants. The 2015 rule imposed prohibitions on discharging FATW and BATW either directly or indirectly to surface waters. The rule reduced the levels of contaminants allowed in FGD wastewater discharges. The changes were based on a technology evaluation conducted by EPA. The 2015 final rule had limited impact on our Upper Midwest power plants, with only one unit, the Allen S. King plant, being required to make capital improvements to address the prohibition on discharging BATW. King is studying options for converting the bottom ash system to a dry handled or fully recycled system. The Sherburne County plant is unaffected until the all coal units are retired at which time there may be residual water in the scrubber solids ponds that may need to be managed onsite

without directly or indirectly discharging the wastewater.

D. Waters of the United States

In 2015, the EPA and the U.S. Army Corps of Engineers (USACE) issued a rule revising the regulatory definition of "waters of the United States" (WOTUS). The rule significantly expanded the universe of land features and water bodies that are subject to CWA jurisdiction. Under the CWA, federal permitting and oversight are required for any activity having the potential to impact WOTUS. Multiple suits were filed against the rule resulting in the 2015 rule being stayed in 28 states, but not in Minnesota. In February 2019, EPA and USACE issued a proposed rule that would revise the 2015 rule.

Our review of the EPA's 2015 final rule indicates that the new definition would impact the Company in a number of ways by adding complexity, cost and delay to project permitting. Current operations would also be impacted by the imposition of new regulatory requirements to previously exempt on-site or adjacent water bodies or ditches. We expect the rule would:

- Increase the difficulty of siting some projects, since many more areas will need to be avoided or be subjected to extensive and time-consuming CWA permitting;
- Complicate certain distribution line routing/re-routing work by triggering a lengthy permitting process before work can be conducted in or near WOTUS – for example, when the Company is required to reroute our lines due to state and local highway projects;
- Complicate the process to site, permit and construct wind and solar facilities, particularly in areas that have isolated water features. Additional time and cost will be incurred to either obtain the permits or to avoid areas that would trigger the need for federal permitting; and
- Increase cost and potential reliability issues as existing facilities, especially substations, must be retrofitted with additional oil-spill prevention and containment features to prevent an oil release from reaching WOTUS.

We are still evaluating the February 2019 proposed rule, but it appears to improve the clarity of the WOTUS definition, making it easier to define what water features will require federal permitting. Our analysis is not yet complete. EPA expects to finalize the proposed rule in 2020.

IV. COAL COMBUSTION RESIDUALS (ASH)

Coal Combustion Residuals (CCRs), often referred to as coal ash, is residue from the combustion of coal in power plants. Two common types of CCRs are fly ash and bottom ash. Fly Ash is a light material with the consistency of talcum powder that is carried from the boiler with the flue gas. This material is captured by pollution control equipment and may be combined with solids generated from air quality control systems designed to reduce SO_x and NO_x emissions. Bottom ash consists of the heavier materials collected from the bottom of the boiler. CCRs are either recycled for beneficial reuse or disposed of appropriately as non-hazardous industrial waste.

Currently the CCRs resulting from the coal combustion at Sherco Units 1 and 2 are disposed of wet within a permitted, engineered, lined surface impoundment as a non-hazardous industrial waste. The fly ash generated from Sherco Unit 3 is disposed of within a permitted, engineered, lined ash landfill located on plant property. The bottom ash generated from all Sherco units is stored within a lined impoundment as a non-hazardous waste until it can be beneficially used as a construction material or properly disposed on site.

The fly ash from the A. S. King plant is transported for disposal at a permitted, engineered, lined commercial landfill as a non-hazardous industrial waste, while the bottom ash from this facility is beneficially utilized in the manufacture of products. Xcel Energy's operations are subject to federal and state laws that impose requirements for handling, storage, treatment and disposal of wastes. These laws regulate CCRs as a non-hazardous waste under Subtitle D of the RCRA. While Xcel Energy's NSP-Minnesota disposal and storage facilities have been regulated by the Minnesota Pollution Control Agency (PCA) for several decades, they have only recently become subject to regulation under EPA's new CCR Rule.

EPA's CCR Rule became effective on October 19, 2015. This rule was promulgated in response to environmental concerns regarding structural failures and releases of ash directly to the environment from large surface impoundments (e.g. the 2008 Tennessee Valley Authority Kingston ash Impoundment failure and the 2014 release from Duke's Dan River Plant), allegations of inconsistent oversight by the states, and the potential for releases from unlined ash impoundments and landfills to impact drinking water sources.

The CCR rule establishes minimum design and operating requirements for CCR landfills and surface impoundments that are comparable to Minnesota's current

requirements under State rules, site-specific permits and operating plans, with specific differences discussed in subsequent paragraphs. Under this rule regulated landfills and surface impoundments are referred to as CCR Units.

The CCR Rule requires ongoing ground water monitoring of each regulated CCR Unit. The rule also defines groundwater protection standards which if exceeded may lead to corrective action. Currently the results from the CCR Rule ground water monitoring program have shown no exceedances of CCR ground water protection standards (GWPS), meaning that no corrective action is required at this time. The CCR Rule liner performance criteria are different than that established under the PCA's state program. As a consequence the Sherco Bottom Ash clay lined impoundment, is deemed lined under the state rule but is deemed unlined under the CCR Rule. Consequently Xcel Energy is in the process of replacing this impoundment with a new, lined impoundment that meets EPA and PCA requirements. Xcel Energy had previously anticipated the need to replace this impoundment and had plans to replace it by 2023. In order to comply with EPA's CCR Rule requirements Xcel Energy accelerated this project to have the new lined bottom ash impoundment available for use by October 31, 2020. Closure of the existing bottom ash impoundment is scheduled to be completed as originally planned in 2025.

Coal operations ceased at the Black Dog site in April 2015. CCR discharges to the three small impoundments present at the site ceased prior to October 19, 2015. These impoundments were closed by removal on December 12, 2016. The CCR materials removed from the impoundments were disposed of in an off-site, lined landfill. The CCR rule requires the completion of groundwater monitoring at closed CCR sites. Groundwater sampling under the detection monitoring program for this site has commenced and a determination as to whether there is a statistically significant increase (SSI) of groundwater constituents over background concentrations for Black Dog Impoundments 1-3 is due by April 17, 2019.

APPENDIX I – SUPPORTING INFRASTRUCTURE – TRANSMISSION & DISTRIBUTION

The goal of a sustainable, cleaner energy future depends upon sufficient infrastructure to support delivery of renewable and distributed generation resources and customer reliability. In particular, modernized transmission and distribution systems are critical to our ability to serve our customers in a reliable and safe manner, deliver growing levels of choice, increase renewable energy, meet the challenges of emerging technologies, and take a holistic view of resource planning.

As we actively prepare our distribution system for the needs of the future, we consider the need for thoughtful investments to meet our core obligation, safely and reliably delivering energy to our customers. We also are focused on adopting smarter technologies to further enable distributed energy resources (DER) on our system. We also face new challenges and opportunities for the transmission grid as traditional baseload units retire, large scale renewables significantly increase, and DER are increasingly adopted. In some cases, such as increasing consideration of distribution-level DER on the transmission grid, changes in the market and planning constructs are underway. Other changes are just coming into view and the planning constructs have not yet caught up. We are adapting our planning practices in the interim to ensure reliability and resilience, and we expect substantial new transmission will be needed to support the transformation that is underway.

Overall, we envision building toward an integrated grid that supports the Company's clean energy transition, leveraging the strength of an interconnected system to make the best use of available resources while continuing to serve our customers with resilient and reliable power. We discuss our transmission and distribution systems in greater detail below, including the ways we expect planning to become more integrated over time.

I. TRANSMISSION

The Xcel Energy Operating Companies NSP-Minnesota and NSP-Wisconsin operate an integrated transmission system (the NSP System) comprising more than 8,400 miles of transmission facilities operating at voltages between 23.7 kilovolts (kV) and 500 kV and approximately 550 transmission and distribution substations. The NSP System serves retail customer loads in Minnesota, North Dakota, South Dakota, Wisconsin, and Michigan. The NSP System is wholly within the Midcontinent Independent System Operator (MISO) footprint, which is part of the Eastern Interconnection.

The transmission grid in the Upper Midwest has seen significant development over the last 10-15 years. These changes have increased both resilience and capabilities to transport renewable energy from the geographic locations where it is abundant to customer load centers, such as the Twin Cities Metro area. But, as discussed in this Appendix, in Appendix J1: Baseload Study, and in conjunction with the Reliability Requirement we developed for this Resource Plan (Appendix J2), the grid is facing new challenges as traditional baseload units retire, large scale renewables significantly increase, and distributed energy resources (DER) are increasingly adopted.

Below, we provide a brief overview of the NSP System transmission grid and our transmission planning efforts to ensure we maintain customer reliability as the grid transforms and the lines between distribution and transmission blur. We then discuss the challenges in maintaining reliability in *every hour of every day* when the resource adequacy construct relies on an average contribution for a single future planning year. While this is reasonable for firm, dispatchable resources, it does not adequately recognize the intermittent nature of renewable resources – particularly as penetration levels grow – and as we discuss, results in gaps in meeting customers' energy requirements. We then discuss the Reliability Requirement that we developed for this Resource Plan to address this challenge and better ensure grid stability and resilience, and customer reliability. We also discuss the challenges and opportunities associated with interconnecting and efficiently utilizing the substantial new renewable generation we will need to meet our goals, given the current state of the MISO interconnection queue and transmission limitations. Finally, in the balance of this section, we discuss timely issues and summarize our Baseload Study.

A. Transmission System and Planning Overview

The Transmission Business Unit centrally manages Xcel Energy's transmission systems (i.e., NSPM, NSPW, Public Service Company of Colorado, and Southwestern Public Service Company) so that energy is safely and reliably transmitted from generating resources (both Company-owned and third-party owned) to the distribution systems serving our customers. While transmission planning is considered separately from resource planning, these two functions are necessarily interrelated, just as the generating resources and transmission infrastructure on the grid are interrelated. Transmission needs are driven by multiple factors including increased customer electric demand, new or retiring generator interconnections that adjust the flows on the existing transmission system, and generation resource choices and the availability of transmission to meet the demand for these resources. The interconnected nature of the transmission system also means that neighboring utilities' decisions (either transmission or generation) have impacts on the NSP System. Finally, as DER grows, even small retail customer changes at the distribution level

may impact the transmission system.

As demonstrated in the Biennial Transmission Plan we submit to the Commission in odd-numbered years, we are constantly reviewing and studying our system to optimize operations and prepare for the future. We independently—and in conjunction with MISO—analyze different futures to assess the system and determine any necessary build-outs, in both short- and long-term planning horizons. Based on these analyses and subsequent implementation, between 2010 and 2018 we invested more than $3 billion in our transmission system. Much of our transmission investment over the recent past has been in implementing the CapX2020 initiative and participating in MISO Multi-Value Projects (MVP), which substantially increased transmission capabilities in the Upper Midwest.

1. Planning Initiatives

MISO and the Company perform ongoing and specialized studies to evaluate necessary projects to address issues in the overall MISO system, including the NSP System.

From these studies and our own technical study efforts in support of the Baseload Study we undertook with this Resource Plan, we believe significant additional transmission development will be necessary as we and other utilities retire baseload generating units and add significant renewable resources to the grid toward our commitment to a clean energy future. We also believe changes to the current planning constructs are necessary to properly reflect the trends underway, to ensure system stability and resilience, and customer reliability.

a. Company Biennial Transmission Projects Report

Pursuant to Minn. Stat. § 216B.2425, every other year, the Company – along with the other Minnesota Transmission Owners[1] – submits a Biennial Transmission Projects Report to the Commission reporting on the status of its transmission system. The Biennial Transmission Projects Report lists specific present and foreseeable future transmission inadequacies; identifies alternatives to address system inadequacies;[2]

[1] American Transmission Company, LLC, Dairyland Power Cooperative, East River Electric Power Cooperative, Great River Energy, Hutchinson Utilities Commission, ITC Midwest LLC, L&O Power Cooperative, Marshall Municipal Utilities, Minnesota Power, Minnkota Power Cooperative, Missouri River Energy Services, Northern States Power Company, Otter Tail Power Company, Rochester Public Utilities, Southern Minnesota Municipal Power Agency, Willmar Municipal Utilities.

[2] Minnesota Transmission Owners define "inadequacy" as essentially a situation where the present transmission infrastructure is unable or likely to be unable in the foreseeable future to perform in a

identifies general economic, environmental, and social issues associated with the alternatives; and summarizes the input that transmission owners and operators gather from the public and local governments to assist in developing and analyzing alternatives.

The 2017 Biennial Transmission Projects Report was filed with the Minnesota Public Utilities Commission in Docket No. E999/M-17-377 on November 1, 2017, and can be found at the Minnesota Department of Commerce's eDockets website at www.edockets.state.mn.us/EFiling or at www.minnelectrans.com. The 2017 report lists more than 90 separate inadequacies throughout the state, including more than 50 newly-identified inadequacies since the filing of the 2015 Biennial Transmission Projects Report. Of the inadequacies identified, 13 involve Xcel Energy.

b. Ongoing MISO Studies

MISO Transmission Expansion Plan (MTEP). MISO has an annual transmission planning process which results in identification of needed transmission facilities.

MISO Generation Interconnection Studies. MISO performs generation interconnection studies to identify facilities necessary to connect new generation resources.

MISO Economic Planning Studies. As part of its planning process, MISO conducts a *Market Congestion Planning Study (MCPS).* The purpose of this study is to determine whether there are transmission projects that could remove transmission constraints and thus more efficiently use available generation resources. The *MCPS* results are reported as part of the annual MTEP report. During the *MCPS* process, projected economic and power flow models are developed which, when analyzed, determine the total production costs that are incurred to provide energy to the MISO load. Transmission constraints – the transmission elements that limit the amount of power that can be transferred between the unused, lower-cost generation and customers – are identified. Through stakeholder discussions, transmission projects are proposed that could mitigate the constraints. The costs for these proposed transmission projects are determined and compared to the amount of production cost savings that could be realized if those projects were in service. The resultant benefit to cost ratio of the projects indicates whether the proposed solutions should be considered for further evaluation for constructability and reliability analysis. Stakeholder review and comments are compiled, and a decision on whether to recommend a *MCPS* project be included in the upcoming MTEP report is made.

consistently reliable fashion and in compliance with regulatory standards.

c. CapX2020 and MVP Regional Development Initiatives

The CapX2020 initiative was a coordinated transmission development effort by a partnership of 11 regional utilities. The results of this coordinated initiative began to be implemented in 2009 and concluded in late 2017. Including the planning, this initiative spanned 13 years, and involved 800 miles of transmission and $2 billion of investment in Minnesota, North Dakota, South Dakota, and Wisconsin.

The approximate lengths, general locations, and in-service dates (ISD) of the CapX2020 projects are as follows:

- *Fargo – St. Cloud – Monticello (ISD mid-2015).* An approximately 240 mile, 345 kilovolt line between Fargo, North Dakota and Alexandria, St. Cloud and Monticello, Minnesota.
- *Brookings County – Hampton (ISD mid-2015).* An approximately 230 mile, 345 kilovolt line between Brookings, South Dakota and the southeast Twin Cities, plus a related 30-mile, 345 kilovolt line between Marshall, Minnesota and Granite Falls, Minnesota. This project is also a MISO multi-value project (MVP).
- *Hampton – Rochester – La Crosse (ISD late 2016).* An approximately 150 mile, 345/161 kilovolt line between Hampton in the southeast Twin Cities, Pine Island near Rochester, Minnesota, and La Crosse, Wisconsin.
- *Bemidji – Grand Rapids (ISD late 2012).* An approximately 70 mile, 230 kilovolt line between Bemidji and Grand Rapids, Minnesota.
- *Big Stone South – Brookings County (ISD late 2017).* An approximately 70 mile, 345 kilovolt line between Brookings, South Dakota and Big Stone City, South Dakota. This project is also a MISO MVP.

MISO MVP is a project type and cost allocation methodology developed through extensive stakeholder discussions in the 2009-2010 timeframe for portfolios of projects that meet one or more of the following three goals:

- Reliably and economically enable regional public policy needs
- Provide multiple types of regional economic value
- Provide a combination of regional reliability and economic value.

The MVP portfolio was intended to enable the delivery of the renewable energy required by public policy mandates, in a manner more reliable and economic than it would be without the associated transmission upgrades. The initial MVP portfolio

was approved in December 2011 and combines reliability, economic and public policy drivers and results in a transmission solution that provides benefits in excess of its costs throughout the MISO footprint.

Xcel Energy was a participant in the following MVP projects:

- Big Stone South – Brookings County 345kV (CapX2020)
- Brookings County – Hampton 345kV (CapX2020)
- La Crosse - Madison 345kV (with ATC, also called Badger Coulee)

With the addition of the CapX2020 projects and MISO MVPs, sufficient transmission capacity has existed for the Company to meet its Renewable Energy Standard (RES) requirements to-date. These projects have improved reliability in the region, addressed local reliability issues, and provided a foundation for the interconnection of new generation resources – particularly the renewable resources that have significantly grown over this timeframe. However, many of these lines planned in the early 2000s and completed over the recent past are already fully- or nearly-fully subscribed.

2. NERC and MISO are Recognizing Potential Resource and Planning Deficiencies

The North American Reliability Corporation (NERC) conducts a reserve margin analysis across all system operators in North America in a report called the Long Term Reliability Assessment (LTRA). The December 2018 LTRA indicated that MISO is one of three regions that are projected to drop below their reference reserve margin levels by the year 2023, unless certain measures are taken.[3] This report indicates that inclusion of Tier 2 resources (those that are in more advanced stages of planning but not yet under construction) would likely allow for the MISO footprint to preserve system reliability. However, the unprecedented rate of announced, but not yet evaluated, baseload generation retirements and uncertainty in future firm capacity additions creates a tension between maintaining reliability and transitioning away from baseload generation. NERC also recently concluded a special reliability study on the compound effects baseload generating resource retirements on the grid.

[3] See "NERC Long Term Reliability Assessment 2018" at 14. Available at: https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2018_12202018.pdf

3. MISO RIIA Study Initiative

In preparation for an expected future grid with high levels of non-dispatchable renewable penetration and declining baseload generation, MISO is undertaking additional studies with respect to its system's reliability and resource adequacy of its system. In 2017, MISO initiated a special initiative called the *Renewable Integration Impact Analysis* (RIIA) that is still underway. We incorporated insights from these studies into our Baseload Study that informed our Preferred Plan. RIIA study seeks to inform future long-term planning by understanding what the power system will need to operate reliably with these high levels of variable resources – specifically by examining operational adequacy, transmission adequacy, system stability, and resource adequacy limitations.

a. Renewables Integration Becomes Significantly More Complex Between 30 and 40 Percent Penetration Levels

In Phase I, the study examined a scenario in which variable generation achieves a 40 percent share of the total capacity on the MISO system. It found that the complexity of operating such a system reliably is significantly higher than that of even a system with 30 percent variable resources. Under the circumstances studied, the system experienced more dynamic stability issues and other operational stressors, and resource adequacy requirements increased. For example, the modeled system exhibited high levels of energy curtailment and very high ramping rates in the hours when variable resources were not always available to meet demand. In this scenario, loss of load projections were narrowed to fewer likely hours during the year, but the probability of occurrence increased significantly over the current state. This points to the value that flexible, dispatchable resources supporting grid stability continue to provide in these circumstances; while they will run for fewer hours as renewable levels on the grid increase, they are needed – and must be able to respond quickly, moving from minimum generation levels to higher levels of output to meet these fluctuations in net load quickly.

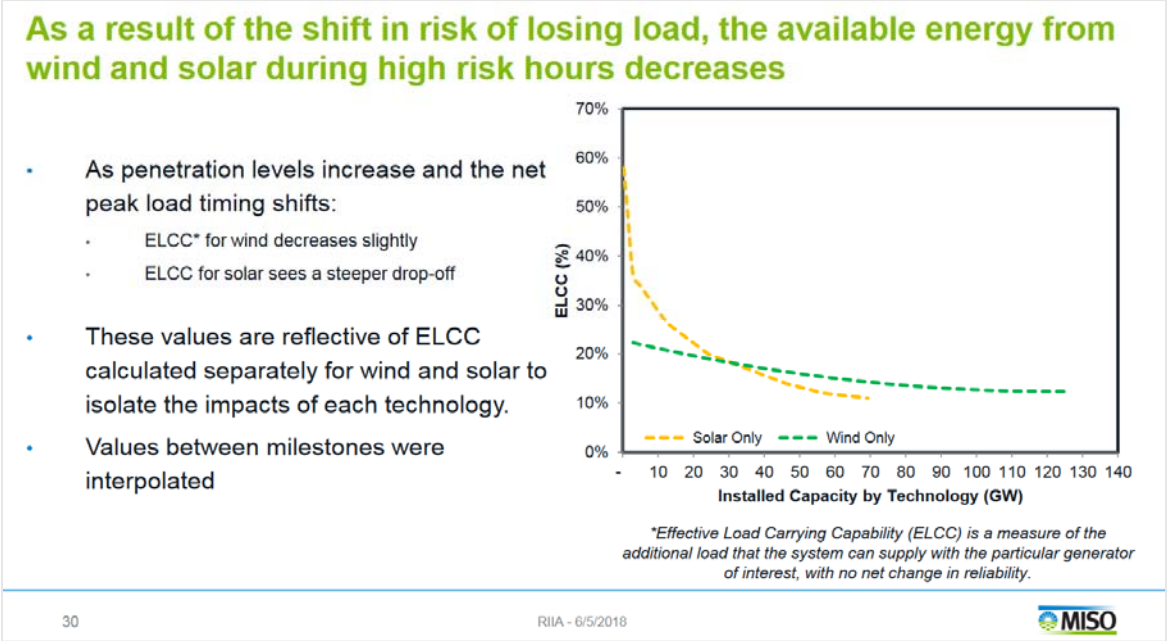
b. Peak Value of Renewables Declines at High Penetration Levels

At high levels of wind and/or solar adoption, the RIIA study found that the accredited capacity values assigned to these resources for resource adequacy purposes degraded – sometimes significantly from current levels. As discussed below, MISO's resource Effective Load Carrying Capability (ELCC) is currently evaluated as an annual average, and forward values are not projected. In reality, however, the capacity value these resources provide to the grid is not consistent – and, as we and other industry members are learning – the capacity values are also subject to diminishing

marginal returns. When a single variable resource type increases its penetration level on the grid, each incremental unit of capacity inherently provides a little less capacity benefit to the system than the previous unit.

The appropriateness of these values in reflecting actual grid conditions is therefore dependent on the pace at which wind and solar penetration increases on the grid – and subsequently, how MISO conducts review and adjusts the values. For example, MISO's RIIA study estimates that solar in particular would experience steep ELCC reductions within the first 10 gigawatts installed – and this value continues to drop off at higher levels of adoption.[4] Further, in particular for these variable assets, the realized capacity value may change throughout the year in accordance with seasonally variable environmental conditions.

Figure 1: Modeled wind and solar ELCC as penetration increases[5]



The operational realities surrounding future variable resource additions and their seasonal aspects aside, we continue to use the MISO-determined accredited capacity levels in our planning. As MISO's planning construct is currently limited to one forward-looking value, this presents a risk as we plan our future system. Applying this single value to a 15-year planning period – now knowing that the value of these resources will degrade as we and others add variable renewables to the MISO system

[4] https://cdn.misoenergy.org/20180418%20PAC%20Item%2003d%20174068%20RIIA190532.pdf
[5] MISO. "Renewable Integration Impact Assessment" Workshop presentation June 5, 2018. Available at: https://cdn.misoenergy.org/20180605%20RIIA%20Workshop%20Presentation213125.pdf

– what appears to be a net capacity surplus today, may look quite different in future assessments.

We additionally note that we may encounter other changes to current resource adequacy accreditations for other use-limited resources in the future as well. In general, resources such as demand response (DR) and energy storage would be subject to declining ELCC values as they become more prevalent on the system, in the same way wind or solar ELCCs realistically decline.[6] Notably, MISO is also considering changes to how it accounts for DR capacity accreditation overall, such as enforcing more stringent testing requirements. MISO is also following up on actual performance during DR events, which may result in accredited value reductions going forward. Both these factors mean that the DR we currently register with MISO and depend on as a baseline resource in our portfolio may not yield the same benefits in future years as we have historically expected.

We see emerging challenges and uncertainties in the broader MISO market and industry that indicate that the present planning constructs to ensure reliability are not fully equipped to address. Large numbers of renewable generation projects are in the MISO queue for interconnection study and facing substantial upgrade costs to connect to the grid. We are also facing a transition on the grid, with many of the current abundant baseload/large central generating stations retiring, and high levels of renewable resources coming online and pending in the MISO interconnection queue – and perhaps long-term, DER. This generation transformation changes the flows and impacts the reliability attributes of the grid in ways we and the industry are just beginning to understand. We discuss these issues in greater detail in the following sections.

B. Current Regional Planning Constructs Must Adapt

MISO is charged with several responsibilities, chief of which is overseeing wholesale energy markets in the member region and planning for bulk system reliability (i.e. transmission planning, generator interconnection, and ensuring sufficient reserve margins). Many aspects of MISO's operations affect how we conduct resource planning, but here we focus primarily on system reliability constructs that will be increasingly tested as we and others transition to a fuel mix that relies on high levels of variable renewable resources.

As we have discussed, MISO and its system reliability oversight organization, NERC,

[6] See Appendix P2: RESOLVE and RECAP Low Carbon Scenario Analysis (E3) for further discussion on how marginal ELCC for DR and energy storage resources may decline as adoption increases.

undertake studies to determine the appropriate level of reserve capacity that should be maintained, what effect a resource retirement has on the broader system, and how increasing renewable adoption will change how they analyze and ensure grid reliability. All of these studies point toward an increasingly complex grid that will have to be carefully managed through the transition to a lower-carbon future. Trends are emerging that raise questions regarding whether and how planning constructs may need to adapt to ensure the system remains reliable as baseload generating units continue to retire and be replaced by carbon-free, but variable, renewable energy.

One of MISO's core responsibilities includes administering resource adequacy requirements to enable the Company and other Load Serving Entities (LSEs) across the region to fulfill their obligation to serve customers reliably. MISO's Planning Reserve Margin (PRM) analysis is one important piece of the current reliability planning paradigm. The PRM is an estimation of how much generating capacity, over and above expected customer load, needs to be present on the system to ensure reliability in all but the most extreme circumstances (called a 1-in-10 year Loss of Load Expectation or LOLE). In the 2018 LOLE report, MISO established reference PRM values for both installed capacity (ICAP) and a value that derates the installed capacity value to account for potential outages (UCAP). These UCAP values are also called "accredited capacity." The UCAP PRM for the NSP System for the 2018-2019 planning year was 8.4 percent, which means that the total available capacity on the system needs to be 8.4 percent higher than the expected system peak load to ensure reliability.[7] LSEs, including the Company, apply this PRM to their system planning to determine their capacity obligation to MISO.

MISO bases the accredited capacity values on the expected average contribution each resource will provide to the grid. For firm dispatchable resources, the UCAP values are determined based on historical individual unit operational performance. For intermittent, or variable resources, UCAP values are based on the average performance of each wind or solar resource project/farm. MISO also performs probabilistic analyses of how much capacity from variable resources can be counted on to contribute to peak demand across the year, and captures this in the ELCC. These administratively-set values have a significant impact on how we achieve our carbon reduction goals while maintaining affordable and reliable service. Currently, MISO assigns our wind generation an average ELCC value of 15.7 percent, meaning that for every 100 MW nameplate of installed wind, only 15.7 MW can be counted as capacity toward the PRM. For new solar resources, in the absence of an observed

[7] Note that these are 2018/2019 values. We discuss these two measures of PRM and how we apply them to the NSP System for this Resource Plan in the Minimum System Needs section.

historical value, MISO assigns the current initial year default ELCC of 50 percent.[8]

There are two primary issues with the current resource adequacy construct that we believe have the potential to impact reliability and resilience, and for which we have taken steps in this Resource Plan to mitigate. First, the PRM relies on an average capacity value for each resource. The variable and intermittent nature of renewable resources means that they are not available at all at times. Relying on them to perform 24 hours a day, 7 days a week – particularly as renewable levels rise and current baseload units retire – presents an unacceptable risk to reliability. Second, with significant increases in renewable resources underway, the industry is beginning to recognize that renewable resource contributions to meeting the system peak declines as their levels increase.

MISO's present resource accreditation process only establishes the ELCC for the next planning year. This short-term approach fails to account for the declining value those resources will provide toward meeting customers' needs over the long-term. Average capacity values for variable resources will not ensure sufficient energy for our customers every hour of every day. Instead, maintaining an adequate level of flexible, dispatchable resources is necessary to effectively integrate high levels of renewables is necessary.

We also know that high levels of renewables result in a declining peak contribution and can create system instability. As MISO has studied high levels of renewable penetration on the grid with its RIIA study, it has recognized that its capacity accreditation framework – the manner by which it assesses variable renewables' ability to contribute to peak demand needs – will likely change as these resources become more prevalent on the grid. However, MISO has not yet developed sufficiently robust forward guidance for resource planning processes to account for how those values might change in the future, creating uncertainty in the resource planning process.

C. Reliability Requirement

In response to the planning gaps identified above, we developed a Reliability Requirement, which we discuss in detail in Appendix J2 and summarize below.

As the Company increases the amount of renewable generation in our system, it is

[8] We performed a solar ELCC study, which was designed to determine potential ELCC values for incremental small scale solar generation installations. *See* Xcel Energy Compliance Filing, Docket No. E999/CI-15-115 (August 17, 2018).

important to recognize that these resources cannot alone reliably provide customers the energy they demand every hour of every day, or maintain the stability of the grid. Until such time as new technologies develop to fully transition the grid to carbon-free resources, some level of load-supporting, firm dispatchable resources is necessary for grid resilience and customer reliability.

As noted above, renewable resources like wind and solar are inherently variable and intermittent, and as penetration of these resources increases, their value to meet peak customer needs decreases. These concerns are not limited to the NSP System, but rather run throughout MISO's footprint – and in other regions with increasing levels of renewables. Within MISO and on the NSP System specifically, the gap between renewable resource performance and customer needs has been most pronounced during (but is not limited to) winter months. Although MISO is beginning to recognize these challenges, its current planning constructs do not yet incorporate any measures to address them. We have therefore developed a Reliability Requirement to inform this Resource Plan and mitigate risks to customer reliability and system resilience as MISO determines how to incorporate these issues into its planning process.

The Reliability Requirement we developed for this Resource Plan ensures we have the right mix of resources on our system every hour of every day to meet our customers' needs. We apply the Requirement in our Strategist modeling, and note that while this concept is essential until MISO evolves its capacity construct to provide better direction – the Requirement has little effect in our modeling for this Resource Plan. The model does not select any firm dispatchable additions as a direct result of the Reliability Requirement until 2031. Figure 2 below outlines the general calculation of the Reliability Requirement.

Figure 2: NSP System Reliability Requirement Calculation – 2020 Example

Peak Demand Proxy – 6,400 MW
Minus Firm DR (Winter) Proxy – (200) MW
Minus Firm Market Supply Proxy – (500) MW

Reliability Requirement – 5,700MW
(Firm dispatchable resources)

We discuss the Reliability Requirement in detail in Appendix J2.

D. Regional Transmission Capabilities are Limited

The current state of grid interconnection processes and transmission capabilities in MISO introduces complexity to our planning processes and how we execute on the plan. An overflowing project queue, delayed interconnection studies, and transmission system limitations impose challenges to the economic viability of new renewable generation, and by association – our ability to execute on our clean energy transition plans. MISO is taking action to address a number of these challenges. There are some mitigation measures we expect to utilize in the near-to-medium term, which include carefully managing our interconnection rights at existing sites. In the longer term, however, we see a lack of new transmission development as a barrier to achieving our clean energy goals.

1. Generator Interconnection Queue Delays and Interconnection Costs

The MISO generator interconnection process is designed to allow generators reliable, non-discriminatory access to the electric transmission system, in a timely manner, while maintaining transmission system reliability. Recently, as the number of proposed projects in MISO has expanded significantly, this process has been mired in delays. Delay impacts are particularly evident in the Definitive Planning Process (DPP) phases, where MISO undertakes generation interconnection studies. Current studies are a number of months behind due to the large number of projects in the queue, and a generator interconnection process that allows late withdrawals from the queue.

Despite some recent process reforms, MISO has not been able to keep pace with the expanding queue. And when projects do make it through the DPP, they are sometimes assigned high transmission system upgrade costs that challenge the projects' economic viability. As of early June 2019, there was over 100 GW of new capacity in the active MISO queue, the vast majority of which was of wind and solar projects.[9] Each cycle of the DPP is handling expanding levels of requested capacity. For example, the recently completed cycle for the MISO West region started out with 31 projects totaling 5,700 MW. The April 2019 DPP study cycle, scheduled to begin in March 2020, includes 58 projects totaling 8,800 GW in the same area.[10] While the level of proposed new renewable projects is a positive indication of aspirational renewable development in the region, MISO has also indicated that a substantial amount of this capacity is speculative, in early stages of project development, or

[9] MISO "Generator Interconnection: Overview." Updated as of June 1, 2019, at: https://cdn.misoenergy.org/GIQ%20Web%20Overview272899.pdf
[10] *See* MISO "Definitive Planning Phase Estimated Schedule." Updated as of June 1 2019. Available at: https://cdn.misoenergy.org/Definitive%20Planning%20Phase%20Estimated%20Schedule106547.pdf

duplicative requests.

Further, the existing transmission system's capability to interconnect new projects without substantial infrastructure upgrades is limited, and thus, the generation interconnection planning studies indicate there will likely be costly upgrades assigned to the prospective generators. In the past, initiatives such as CapX2020 and MISO MVPs socialized a substantial level of transmission infrastructure investment across a large swath of benefitting MISO members, and created the ability to integrate large amounts of new renewable energy. However, renewable resources, and wind power in particular, expanded on the MISO grid faster than expected. As a result, the capacity that CapX2020 and the MVPs created has been largely used. Since these early initiatives, few new transmission lines have been proposed or approved for the purposes of renewable integration.

Generally speaking, this translates to substantial transmission upgrade costs being assigned to the generation projects in the queue. To illustrate, in the recently completed MISO West DPP cycle, the 5,700 MW of studied projects were expected to incur approximately $3.2 *billion* in transmission upgrades if all of them were to interconnect to the system.[11] Such high transmission system upgrade costs can render projects uneconomic, forcing them to withdraw from the queue and requiring additional MISO study on the remaining projects.

2. *Physical and Process Limitations between Regions Further Slows Progress on Clean Energy Development*

Limitations on transmission infrastructure and coordination, both within MISO and between MISO and the Southwest Power Pool (SPP), illustrate further challenges. Within MISO, the transmission system is showing constraints and thus slowing progress toward a cleaner energy future across the Upper Midwest system. Currently, wind generation from the western part of MISO flows toward the load centers in the east, such as the Twin Cities Metro area and load centers beyond the transmission interconnection between Minnesota and Wisconsin. However, existing west-to-east transmission capacity is, at times operating at its limit. The transmission interface across the Minnesota-Wisconsin border in particular is currently stability-limited, and trying to force additional renewable energy through these lines could result in voltage collapses in Northern Wisconsin that would destabilize the grid. Curtailing this energy at its source in the west is operationally and economically inefficient – keeping

[11] *See* "MISO DPP 2016 August West Area Phase 1 Study." Report Number: R008-18. Siemens, September 20, 2018, at xvii.
https://cdn.misoenergy.org/GI_DPP_2016_Aug_West_Phase1_SIS_Report277263.pdf

us from fully utilizing the inexpensive and clean energy to which we have access. However, without additional transmission development, we will more frequently encounter this problem as we add more renewable generation to our system.

Further, coordination (or historical lack thereof) between MISO and SPP introduces challenges to increasing and utilizing more clean energy. First, for projects that can be considered interregional in nature, a project must currently meet economic benefit hurdles in a joint review, as well as separate MISO and SPP regional evaluations. This slows the process significantly, and may overestimate the amount of interconnection upgrades required, adding to project uncertainty and cost. Second, although our load and generation are fully within MISO, the nature of power flows inevitably results in some of our energy entering the SPP system. In turn, both MISO and SPP may charge to transmit that energy from the point of generation to the load, challenging a project's economic viability or raising customer costs for projects already online.

Finally, MISO and SPP disagree on what should happen when one region or the other has to "lean" more on the system than its contracted delivery amounts for a certain time. Where SPP would levy penalties in this scenario, MISO views this situation as a normal and acceptable result of an integrated grid. All of these issues increase transaction costs and uncertainty for a given generation project coming online, and represents a potential barrier to efficiently bringing additional renewable generation to the grid.

3. MISO is Taking Action to Address the Current Process Issues

In response to direction from FERC and a recognition of the challenges described above, MISO is undertaking several actions that could serve to mitigate challenges to bringing new, clean resources online. In essence, these actions allow generation owners to leverage existing interconnection agreements to maximize utilization, and fit renewable additions into the relatively few remaining open spaces on the grid. While we expect these processes to mitigate some of the near-term challenges to additional renewable capacity, they do not address all challenges – in particular, our ability to depend on neighboring regions for renewables and maintaining reliability; we expect that longer term solutions will eventually need to be developed.

a. Generator Replacement Process

Interconnection study delays and speculative queueing are challenges not only to projects that are actually commercially-viable, but also to generation owners who are looking to retire aging assets. Companies that are required to meet a certain level of reserve capacity, like Xcel Energy, face potential compliance and commercial risk if

we retire existing assets without the ability to re-utilize that interconnection capacity.

Recognizing these issues, MISO filed, and in May 2019 received approval for, a proposed Replacement Generator Process as part of its Attachment X tariff. This modification intersects with Attachment Y with regard to generation replacement and interconnection rights of current generation owners when a resource retires. The change to Attachment X allows current generation owners to retain and reuse the interconnection rights when a resource retires, within certain technical and timing limitations on the new generator.[12] The new generating units could be developed on the same site, or on a site in close proximity that uses the same grid interconnection point. Per the new tariff language, the replacement generation resource would need to go into service not later than three years after the existing generator retires. Importantly, these replacement projects would be studied outside the traditional DPP timeline, because the transmission infrastructure in the area was built to accommodate the large amount of generation associated with the current generating facility – and customers should be able to continue to take advantage of this infrastructure that they have already paid for rather than fund alternative network upgrade costs. This avoids the significant delays and costs associated with the DPP process.

Maximizing use of existing interconnection rights is essential to timely and cost-effective achievement of the fleet transformation that we set in motion with this Resource Plan. This Tariff change is an important development that will help to facilitate the transformation in a timely and cost-efficient manner for our customers.

b. FERC Order 845 Opens Additional Opportunities for Generation Owners

In 2018, FERC issued Order 845, *Reform of Generator Interconnection Procedures and Agreements*, that also opens additional opportunities for generation owners to add resources to the system outside the normal interconnection queue process.[13] First, the Order directs all transmission providers to develop a procedure to allow interconnection customers to use surplus availability at an existing point of interconnection without that new project entering the full MISO queue and planning process, within certain technical limitations. MISO has referred to surplus interconnection availability as "Net Zero" interconnection because the addition of

[12] In summary, these changes allow for transfer of interconnection rights from a retiring generation resource to a replacement resource that: (1) is located at the same point of interconnection as the retiring resource, (2) is less than or equal to the generating capacity of the retiring resource, and (3) does not result in an adverse impact to the transmission system. *See*: https://www.ferc.gov/CalendarFiles/20190515181059-ER19-1065-000.pdf

[13] *See:* https://www.ferc.gov/whats-new/comm-meet/2018/041918/E-2.pdf

this new project would not result in an overall increase to the interconnection capacity requirements of the site; rather, it would be expected to increase the overall *utilization* of the interconnection site. While MISO allowed Net Zero resources prior to FERC 845, the new Order also allows existing interconnection rights owners the first right to utilize the surplus availability on that interconnection. It also revises the definition of a generating facility to explicitly include energy storage resources. These actions work to support generation owners increasing renewable utilization on existing interconnections, and could support future project hybridization (e.g. solar and storage or wind and storage).

c. Substantial Challenges Remain

We expect that generator replacement, Net Zero, and other FERC Order 845 implementation efforts will alleviate some of the barriers to planning and executing on a future with substantial renewable additions. However, these do not address the underlying challenges around queue length and timeline, intra-MISO and interregional seams congestion challenges, and integrating high levels of renewables reliably and affordably. MISO has recently attempted to mitigate the queue volume challenge by proposing process reforms that increase the stringency of entering this phase of interconnection process; however, while recognizing the challenges MISO faces, FERC recently rejected the proposal.[14] While the Company and others have begun contemplating new MVP-like projects, the lack of alignment across MISO and long lead-times required for such projects mean that these challenges are unlikely to be sufficiently resolved in the near-term.

E. Summary – 2020-2034 Upper Midwest Resource Plan Baseload Study

With this Resource Plan we provide a Baseload Study as Appendix J1. We undertook this study as an outcome from our most recent Resource Plan in which the Commission required the Company to continue its study of potential baseload resource retirements.[15] We started this work as part of our last Resource Plan, as we took action to transition our fleet to achieve dramatic reductions in carbon emissions. Specifically, we studied the technical implications of retiring two of our coal plants – Sherco Units 1 and 2. In conjunction with this Resource Plan, we performed technical analyses to more broadly examine the issue of orderly retirement of our remaining baseload generating units – namely, A.S. King, Sherco Unit 3, Monticello Nuclear, and Prairie Island Units 1 and 2.

[14] *See* FERC "Order Rejecting Tariff Revisions re: Midcontinent Independent System Operator, Inc. under ER19-637." Available at: https://elibrary.ferc.gov/idmws/file_list.asp?accession_num=20190319-3076
[15] *See* Docket No. E002/RP-15-21, Order Point 14(a) (January 11, 2017).

To understand the technical impacts of retiring one or more baseload generating units, we perform engineering analyses on simulations of the Unit changes that assess the results against established industry reliability and operating criteria. When performing technical studies, we simulate a number of varied conditions that can consider changes in customer loads, projected changes to the generation mix, and ways to use the transmission system most efficiently.

The Baseload Study in this Resource Plan is comprised of four primary components:

- **Midcontinent Integrated Systems Operator (MISO) Attachment Y2 preliminary retirement studies**, which assessed various single Unit and combined Unit retirement scenarios for thermal and voltage concerns,
- **Xcel Energy Transmission Reliability studies**, which examined system stability and response impacts associated with baseload generating resource changes on the NSP System and on neighboring systems,
- **Industry insights**, including the North American Electric Reliability Corporation (NERC) *Generator Retirement Scenario Special Study* and the MISO *Renewable Integration Impact Analysis* (RIIA), which provide important insights into the combined effects of baseload generator retirements in a region and grid impacts at increasing levels of renewables penetration, and
- **A focused Strategist analysis**, which examined the economic implications of various Unit and combined Unit retirements at different points in time.

The technical studies generally analyze the way power flows over the grid and search for places where the system might overload or fail, assuming specific circumstances. While these studies are essential and provide important insights, our decades of operating and studying the existing system also provides valuable insights and perspective toward assessing potential impacts from NSP System grid changes. We incorporated this experience into our analysis of impacts. We also supplemented our technical study efforts with relevant industry initiatives that examine the compound impacts of aging baseload retirements and increasing levels of renewable generation – similar to the issues facing the NSP System. The studies use the best available information at the point in time that they were conducted. However, the grid is dynamic, and expected conditions will change when new generation comes online, existing generation retires, new transmission lines are constructed, or existing lines are reconfigured; in addition, reliability measurement criteria may change. The results therefore are a point-in-time representation of the technical issues we expect would occur in a studied scenario.

The MISO Y2 and our Reliability Studies identify grid impacts and potential transmission mitigations necessary to resolve the respective issues the studies identified. MISO performed its Y2 Studies in accordance with their Business Practice Manuals, which generally focus on thermal and voltage issues.[16] We used the MISO planning level estimated mitigation costs from the Y2 studies as an input to our Strategist modeling of the baseload unit retirements. While these may not be the final mitigations, they provide a proxy of potential costs to inform the economic aspect of our Baseload Study. Our technical studies supplemented the MISO analysis to examine traditional NERC reliability measures such as system stability and response. This is an important complement to the MISO Y2 studies to provide a more robust look at potential impacts from baseload changes on the NSP system and regional MISO grid.

The results of our Baseload Study informed the Preferred Plan we propose in this Resource Plan, which includes the following baseload actions: (1) Retire our remaining two coal units early – King in 2028 (nine years early) and Sherco 3 in 2030 (ten years early), and (2) Extend the operation of Monticello nuclear 10 years through a license extension, to 2040.

Other conclusions and insights from this Study include:

- The retirement of our current baseload units must be orderly, and will be impacted by decisions other MISO generation owners make regarding their baseload units.
- We must maintain sufficient firm dispatchable, load supporting resources to ensure customer reliability and to support integration of higher levels of renewable resources.
- Changes in the MISO planning construct are necessary to properly recognize the inherent variable and intermittent nature of renewable resources in meeting customer needs every hour of every day.
- Significant new regional transmission development will be necessary to support increased levels of renewable resources and to support the retirement of baseload units.
- From an economic perspective, the scenarios that included early coal retirements and nuclear extensions had the most favorable present value.

Insights gained from this Study also helped to inform our development of a Reliability

Requirement (discussed in Appendix J2), which bridges the gap between current regional planning requirements and necessary changes to account for: (1) the variable contribution renewable resources provide to the system, (2) the lack of long-term regional system planning guidance for the expected contribution of renewable resources as penetration levels rise, and (3) the need for sufficient firm dispatchable, load supporting resources to reliably integrate increasing levels of renewable resources.

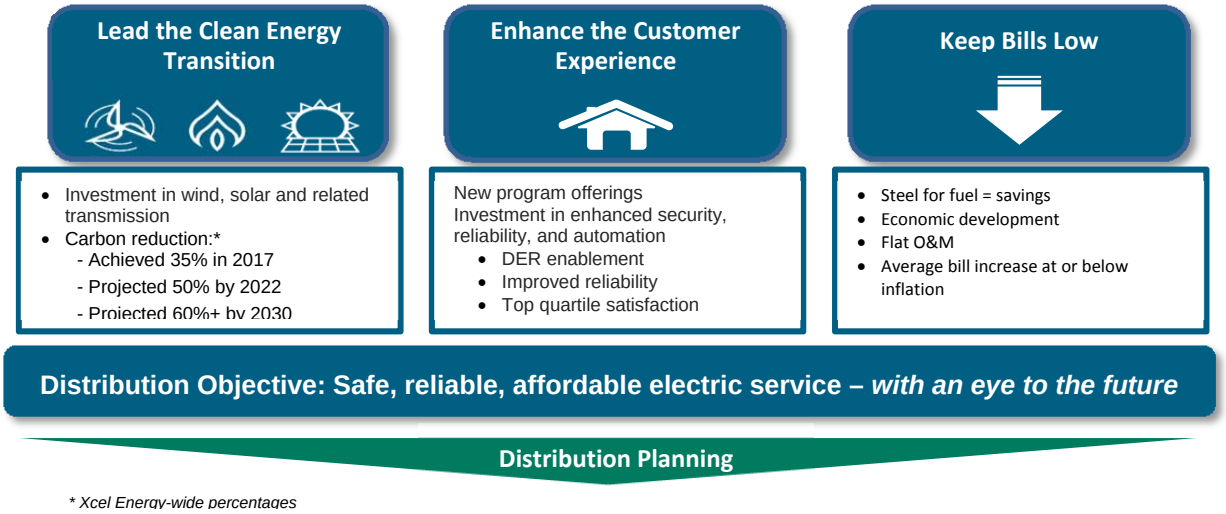
II. DISTRIBUTION

The electric utility industry is in a time of significant change. Increasing customer expectations and technological advances have reshaped what customers expect from their energy service provider, and how those services are delivered. Technologies that customers can use to control their energy usage, such as smart thermostats, electric vehicle (EV) chargers, smart home devices, and even smart phones, are evolving at a fast rate. Influenced by other services, customers have come to expect more now from their energy providers than in the past, including greater choices and levels of service, as well as greater control over their energy sources and their energy use.

At the same time, major industry technological advances provide new capabilities for utility providers to manage the electric distribution grid and service to customers. Electric meters are now equipped to gather more detailed information about customer energy usage, which utilities can leverage to help customers better understand and manage their usage. Other advanced equipment on the grid is able to sense, communicate, and respond in real time to circumstances that would normally result in power outages. Grid operators can also get improved data to better and more proactively plan and operate the grid. These advancements form the foundation for a flexible grid environment that helps support two-way power flows from customer-connected devices or generating resources (such as rooftop solar) and provides utilities with a greater ability to adapt to future developments.

The foundation on which these capabilities rest is safe, reliable energy. Our strategic priorities of enhancing the customer experience, leading the clean energy transition, and keeping customer bills low are embedded in everything that we do – including the way that we plan our distribution system.

Figure 3: Xcel Energy Strategic Priorities – Applied to Distribution



Distribution planning has historically – and still largely today –involved analyzing the electric distribution system's ability to serve existing and future electricity loads by evaluating the historical and forecasted load levels, and utilization rates of major system components such as substations and feeders. Customers traditionally have had limited information about their energy usage and few choices in how they received information, had questions answered, and paid utility bills or conducted other necessary business with their utilities. For the most part, customers were content to receive a monthly paper bill from their utilities and were unaware and unengaged in whether the energy came from renewable or non-renewable sources.

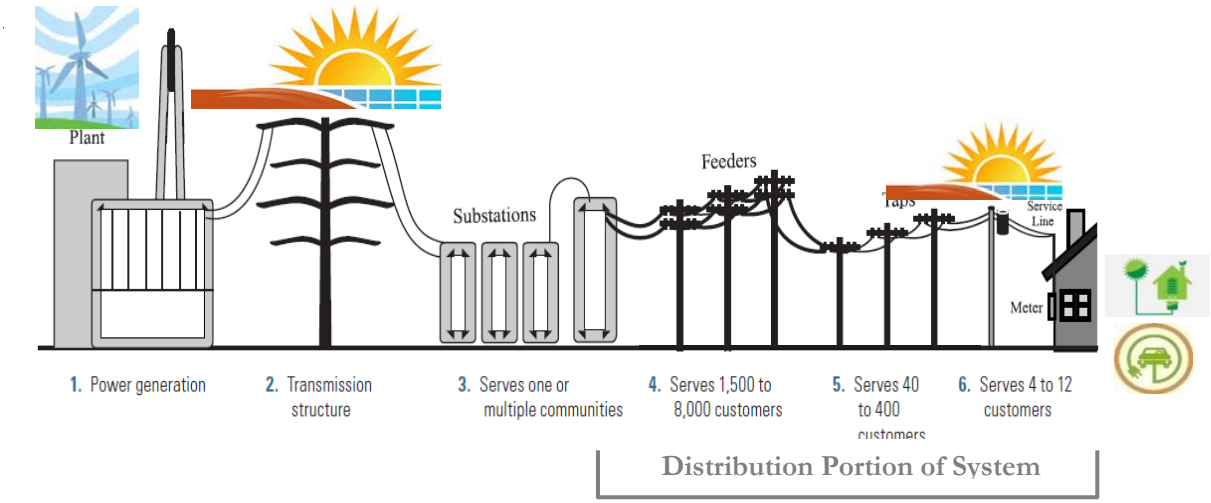
Now, instead of planning just for load, utilities will need to analyze the system for future connections that may be load *or* generation. Also, utilities will increasingly need to view their operations and customer tools from their customers' perspectives. This step change in the distribution utility business will require utilities to plan their systems differently, which will involve not only new processes and methodologies but also new and different tools and capabilities.

Like other aspects of the industry that are transitioning and advancing, we are on the forefront of integrated distribution planning. We submitted the first Integrated Distribution Plan (IDP) in Minnesota November 1, 2018 – which was also among some of the first IDPs nationally. We are taking steps to align and integrate our distribution, transmission, and resource planning processes. We also are in the process of evaluating and procuring the next generation of distribution planning tools, which are needed to increase our forecasting and analysis capabilities and impact the integration of planning processes.

A. System Overview

The electrical grid is composed of generating resources, high voltage transmission, and the distribution system, which is the vital final link that allows the safe and reliable flow of electricity to serve our customers. We provide an illustration of a modern electrical grid below.

Figure 4: Illustrative Electrical Grid



The poles, lines, and cables that comprise the distribution system connect individual residents and business to the larger electrical grid. The system has been developed for the efficient distribution of power, with lines routed as directly as possible. Geography, however, plays a dominant role in the ultimate design of the system; the location of lakes, road and developments dictate the siting of much of the distribution infrastructure.

Distribution substations are sized for anticipated load at a particular site, and often consist of one to three transformers. Site selection for substations is based on the availability of a transmission source, proximity to the load being served, total ownership costs and reliability considerations. Incremental transformers and feeders may be planned at substation sites to meet future load demand. Where possible, redundancy is built into the system to maintain reliability. Taps are the smaller line segments that leave the mainline and fuses or reclosers are installed at those connection points, which open if a fault develops on the tap. This prevents the remainder of the system on that feeder from having their service interrupted, thus isolating the outage to just the customers beyond that fuse. At the customers' site, service transformers feed lower voltage secondary conductors. These conductors

deliver the low voltage power to meters at customers' homes and businesses.

The NSPM electric distribution system serves 1.5 million customers (1.3 million in Minnesota) – and is composed of 1,177 Feeders, approximately 15,000 circuit miles of overhead conductor, and over 11,000 circuit miles of underground cable.[17] The distribution portion of the grid, and the services that the Distribution organization provides, are generally the aspects of our electric service that are most visible to our customers. In terms of reliability, we rank nationally in the 1st quartile.[18]

Key Distribution functions include operating the distribution system, restoring service to customers after outages, performing routine maintenance, constructing new infrastructure to serve new customers, and making upgrades necessary to improve the performance and reliability of the distribution system. We are also out in the community during and after severe weather events as part of our industry-leading storm response efforts to ensure safety, and to promptly restore service to customers.

Key overall Electric Distribution business priorities are:

- *Operational Excellence.* Improve reliability performance level.
- *Grid Modernization.* Install key equipment and systems to operate the new modern grid including monitoring and control, Advanced Distribution Management System, and system efficiency. Targeted renewal of aging, unreliable, or obsolete components and systems (i.e. underground cable, poles, 4kV systems)
- *System Health.* Targeted maintenance of key assets designed to improve reliability and safety – wood poles, substations transformers & breakers, vegetation management.
- *System Capacity Additions.* Installation or reinforcement of key substations and feeders to serve new load and provide backup under emergency conditions (focus on high consequence events).

Distribution priorities and budgets recognize that customers want reliable and uninterrupted power. We therefore must not only proactively maintain our system by making capital improvements when necessary to improve reliability and safety for our customers – we must also manage our budgets to be able to respond to outages

[17] In this context, the number of customers is based on the number of electric meters.
[18] Results for the NSPM operating company, as measured by SAIDI and SAIFI. *See IEEE Benchmark Year 2018, Results for 2017 Data* at:
http://grouper.ieee.org/groups/td/dist/sd/doc/Benchmarking-Results-2017.pdf

caused by severe weather, mandatory work such as relocation of our facilities, and other conditions that cannot be foreseen with a high degree of accuracy. While the immediacy of customer reliability is a reality and a primary focus, in addition to these core activities, our investment plan reflects strategic investments to advance distribution grid capabilities, increase our system visibility and control, and enable expanded customer options and benefits. We are also planning for enhanced distribution planning tools that will equip our system planners with the capabilities to perform DER scenario analysis in our annual planning processes, better facilitate our incorporation of non-wires analysis (NWA) into the analysis we perform to ascertain the best way to meet system capacity needs, and begin in earnest the integration of planning activities at all levels of the grid.

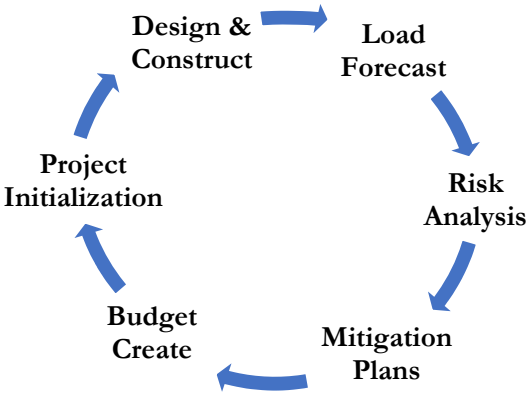
B. System Planning

An important aspect of distribution planning is the process of analyzing the electric distribution system's ability to serve existing and future electricity loads by evaluating the historical and forecasted load levels and utilization rates of major system components such as substations and feeders. We also consider Hosting Capacity analysis an important aspect of our system planning. We discuss both of these planning activities in this section.

1. Annual System Planning

We do this annually, and additionally conduct analyses during the year in response to new information, such as new customer loads, or changes in system conditions. The process begins with the forecast of peak customer load and concludes with the design and construction of prioritized and funded capacity projects, as illustrated in the below Figure.

Figure 5: Annual Distribution Planning Process



Planning Engineers rely on a set of tools to perform the annual full system snapshot, ongoing distribution system assessments – including assessment of specific DER interconnections – and long-range area assessments. We see our planning practices evolving to analyze future electricity *connections*, rather than just loads. However, we will need to advance our planning tools and capabilities to facilitate greater capabilities to factor-in DER and to more systematically be able to evaluate NWA. Enhanced planning tools have started to emerge in the industry, but will take some time to mature. Toward that end, we have been participating with others in the industry to examine the types of capabilities that may be needed. We also are in the process of evaluating and procuring the next generation of distribution planning tools, which are needed to increase our forecasting and analysis capabilities and impact the integration of planning processes.

2. *Non-Wires Alternatives*

Non-Wires Alternatives (NWAs) are emerging as another advanced distribution planning application. While a nascent concept only a few years ago, the United States has seen a significant rise in the number of NWA projects proposed and being implemented. States with high DER penetration and/or aggressive regulatory reform, like New York, California, Oregon, and Arizona, are leading the way. Decreasing DER costs in combination with slow or flat load growth may present opportunities for utilities to address pockets of load growth using DER over traditional build out of distribution infrastructure, like reconductoring, transformer replacement, or even new substations. Unlike traditional infrastructure projects, which typically offer fixed capacity increases at known locations, non-traditional solutions often have varying operating characteristics based on their location or the time of day they are used.

More tactically, NWA analysis processes consider several things: a set of criteria for

determining which traditional projects are suitable candidates for NWA, processes to develop portfolios of solutions (including both third party resources and non-traditional utility assets), a mechanism to evaluate the costs and benefits of the NWA relative to the traditional solution, procurement processes, and standards to ensure equitable reliability and performance. For implementation and deployment, currently we are seeing NWA solutions which require a disparate set of systems to separately operate the different elements of equipment that would comprise an NWA portfolio solution (e.g. a battery- only platform or demand response- only mode).

Without integration across different systems, this makes the facilitation of NWA a custom, one-off solution that requires extensive oversight and management. To-date, analysis we have performed has determined that the cost of incorporating DER as the primary risk mitigation is at this time still more costly than traditional solutions. However, as technology advances and manufacturing evolves, DERs have the potential to quickly become a cost competitive option. As such, we are working diligently with research groups, internal and external stakeholders, and other utilities that are also incorporating DER planning in order to refine the process of having NWAs solve traditional distribution system deficiencies.

3. Hosting Capacity

We recognize hosting capacity as a key element in the future of distribution system planning. We anticipate it has the potential to further enable DER integration by guiding future installations and identifying areas of constraint. In compliance with Minn. Stat. § 216B.2425 and by order of the Commission, we conducted and submitted annual hosting capacity studies in 2016, 2017, and 2018.[19] We use the EPRI DRIVE tool for our analysis. EPRI defines hosting capacity as the amount of DER that can be accommodated on the existing system without adversely impacting power quality or reliability – and introduced the DRIVE tool as a means to automate and streamline hosting capacity analysis. Our studies have provided hosting capacity results by feeder to serve three purposes: (1) provide an indication of distribution feeder capacity for DER, (2) streamline interconnection studies, and (3) inform annual long-term distribution planning.[20] We expect to continue to evolve our hosting capacity analysis to meet emerging trends and customer needs.

[19] *See* Distribution System Study, Docket No. E002/M-15-962 (December 1, 2016), Hosting Capacity Report, Docket No. E002/M-17-777 (November 1, 2017), and Hosting Capacity Report, Docket No E002/M-18-684 (November 1, 2018).
[20] See Integrated Distribution Planning Report Prepared for the Minnesota Public Utilities Commission, ICF International (August 2016).

C. Distributed Energy Resources

We continuously evaluate new technologies, new system designs, new equipment, and new operational methods in order to continue to meet the needs of the distribution system in a changing energy environment. These new technologies include emerging advanced grid tools or other advanced field devices with monitoring, controlling, and other capabilities that better enable DER and provide for a more adaptable system.

Some customers are choosing DER, which can reduce customer consumption and even provide energy back to our system from decentralized locations on the grid. Examples of DER include, but are not limited to: rooftop solar panels, energy storage, community solar gardens, or the energy efficiency and demand response enabled by a smart thermostat or time of use electric rate. We are anticipating and preparing for increasing DER penetration levels on our system.

Our customers' adoption of DER and new types of load mean that consumption patterns from our centralized power system are changing. This can represent an opportunity: if we can harness the benefits of these resources to make demand more flexible, we can use this to better match demand to energy production from our large, variable renewable resources. For example, we could utilize managed or "smart" charging of electric vehicles (EVs), to delay charging to off-peak hours or to times when renewable output is the highest. We could also use advanced metering technology alongside customer programs and tariffs to more readily enable load shifting away from peak hours.

DER is also coming onto our system in the form of electric transportation options – enabling not only flexible load opportunities but also broader economy-wide emissions reduction – and we have developed several programs and rate options to encourage that adoption. However, we still often do not have visibility into which technologies, and at what pace, customers will adopt and thus, how we should plan for that changing load to affect our grid needs in the future. While the opportunities are exciting, it is also important to recognize that customer adoption of DER and new types of load behind the meter introduces uncertainties in our planning processes, particularly if we do not have adequate visibility into how and when that new DER or demand is coming onto our system.

The distribution system was initially built to support one-directional flows of energy. Increased DER penetration levels pose new challenges to the distribution system to accommodate two-directional flows. As DER installations increase in an area, feeders or substations may require further analysis to ensure this equipment is adequate to continue providing sufficient power quality and reliable service. Safety is a key

concern with higher volumes of distributed energy, as are operational challenges presented by the variability of sources like solar photovoltaic and electric vehicles. DER is also increasingly expected to impact the transmission system, so distribution and transmission planning processes are becoming increasing interrelated.

The Federal Energy Regulatory Commission (FERC) has engaged in the DER trend through its Order No. 841, which addresses participation of storage resources at the transmission and at the distribution level in wholesale markets. We support Order No. 841 as it relates to resources interconnected at transmission level, but have concerns about its implementation as it relates to storage resources interconnected at distribution level.[21] We also have concerns about FERC's proposal in Docket No. RM18-9-000, Participation of Distributed Energy Resource Aggregations in Markets Operated by Regional Transmission Organizations and Independent System Operators, which would expand the requirements of FERC Order No. 841 to all types of DER interconnected at distribution level, not just storage resources.[22]

We addressed what we see as current challenges, which become more significant at higher penetration levels, in comments submitted to FERC. These challenges include:

- *Metering.* Participation of distribution-interconnected storage resources raises the question about how metering will distinguish between charging for wholesale purposes as opposed to charging for retail usage in the case of dual-use facilities. Charging for retail usage should be subject to state-regulated retail rates while charging for wholesale purposes would, under Order 841, be subject to FERC regulated wholesale rates. We are not aware of any metering arrangement that can distinguish between charging for wholesale purposes and charging for retail purposes in the case of a dual-use facility. It should be incumbent upon the resource owner to provide sufficient documentation to ensure that any dual-use resource can be metered in a manner that can distinguish between charging for retail use as opposed to charging for wholesale use. Otherwise, cost shifts to other retail customers will occur as a result of such a resource avoiding payment of full retail rates when it is charging a storage resource for what will ultimately be usage for a retail purpose.

[21] XES filed a request rehearing of various aspects of FERC Order No. 841 as it relates to resources interconnected at distribution level. A copy of XES's request for rehearing is available at this link: https://elibrary.ferc.gov/idmws/file_list.asp?document_id=14651369

[22] A copy of XES's comments in FERC Docket No. RM18-9-000 is available at this link: https://elibrary.ferc.gov/idmws/file_list.asp?document_id=14682284. These comments largely capture input provided in XES's original comments in Docket Nos. RM16-23-000 and AD16-20-000 and XES's request for rehearing in those dockets. FERC declined to accept these comments into the record in Docket No. RM18-9-000 because FERC deemed they were duplicative.

- *Distribution Operations.* Distribution system operators (DSO) need to have the capability to monitor activities of DER in the wholesale market and potentially take action to curtail market sales if such sales will impair reliable distribution system operations. The need for such capabilities will increase as DER penetration increases. The mechanisms to manage these operations will require enhanced communications systems between the DSO, DER, and market operator; software that can monitor distribution system impacts and identify reliability issues and solutions; and additional operations personnel to effectively manage the impacts of DER participation in markets. Cost causation principles dictate that the DER owners and operators should be responsible for the costs associated with these enhancements because such costs would not be incurred "but for" the participation of DERs in wholesale markets. However, absent fairly significant DER penetration levels it is not clear how these costs can be effectively allocated and recovered. At low penetrations there will simply be an insufficient number of customers to bear the costs of these infrastructure upgrades. FERC has not proposed a mechanism to address this issue. In the meantime, DSO will have to find ways to manage DER resource participation reliably, cost-effectively, and in a manner that does not shift costs to other customers.
- *Distribution system upgrades.* Existing distribution systems were not built to manage large outflows of energy that would be associated with market sales. Further, distribution systems are not as flexible as transmission systems and therefore are less able to effectively handle the types of system flows that will occur with DERs participating in markets. Distribution interconnection studies will be more complex and will identify potentially significant feeder and substation upgrades needed to enable market participation by DERs. The costs of such upgrades should be directly assigned to the DER causing such costs to be incurred.
- *Wholesale market issues.* In addition to the direct distribution-level impacts of DERs participating in markets, there are a variety of other issues that must be addressed at the wholesale market level. These issues include the ability to determine where individual DERs involved in an aggregation are located in order to ensure that resources are paid the appropriate nodal price, whether technology exists to effectively manage the state of charge of storage resources, and whether market software can effectively be deployed to manage large numbers of relatively small resources.

MISO was required to make a compliance filing with FERC by December 3, 2018 and has a year thereafter to implement provisions of its compliance filing. One of the key

aspects of MISO's compliance filing was relationship between MISO, the DER, and the applicable DSO. FERC is currently evaluating MISO's plans to implement Order 841. Implementation is required by the end of 2019 absent an extension. The Company is also evaluating whether additional steps may be needed to handle the interface between itself, the owners of DER resources, and MISO. Issues that the Company is evaluating include direct assignment of distribution system upgrade costs incurred due to DER participation in wholesale markets, distribution wheeling rates, the need for a DER to establish to the satisfaction of the utility that it has metering capability needed to ensure that it does not charge a storage resource at wholesale rates for retail usage, mechanisms to limit DER output to the extent that reliability of the distribution system is compromised by the DER's activities, and cost recovery for services provided by the distribution system operator to the DER.

We plan to evaluate this issue further and take appropriate steps to move forward to ensure that DER participation in wholesale markets is not subsidized by other retail customers and that such participation is conducted in a manner that does not threaten reliability of the distribution system.

We are taking action to improve our planning tools and modernize our system to more readily integrate increasing levels of DER that we believe are inevitable. We discuss these plans as part of our overall advanced grid initiatives in Part _ below.

D. Advanced Grid Initiative

We are on the forefront of many of the issues and changes underway in the industry and have developed our advanced grid initiative to address them. In addition to the significant steps we have taken to implement and improve our hosting capacity analysis, we are in the process of implementing an Advanced Distribution Management System (ADMS). The ADMS is foundational to advanced grid capabilities that will provide the visibility and control necessary for enhanced planning and significant DER integration. We are also implementing a Time of Use (TOU) pilot, which implements new residential TOU rates, and the installation of Advanced Metering Infrastructure (AMI) meters, in two communities in the Twin Cities metropolitan area, providing select customers with pricing specific to the time of day energy is consumed. This pilot also provides participants with increased energy usage information, education, and support to encourage shifting energy usage to daily periods when the system is experiencing low load conditions.

We also are poised to propose further foundational advanced grid capabilities, including a full AMI implementation, a secure and robust Field Area Network (FAN),

and significant reliability improvements for customers through Fault Location, Isolation, and Service Restoration (FLISR). In addition to transforming the customer experience, these foundational investments will allow us to advance our technical abilities to deliver reliable, safe, and resilient energy that customers value. As an example, FLISR and ADMS will reconfigure the grid to reduce the numbers of customers affected by an outage and provide better information to outage restoration crews to speed up their response or avoid those outages in the first place. These foundational investments also lay the groundwork for later years. The secure, resilient communication networks and controllable field devices deployed today through these investments will become more valuable in the future as additional sensors and customer technologies are integrated and coordinated.

We envision that our customer strategy will leverage the more refined customer usage data captured by AMI meters and communicated to utility systems through the FAN to enable new rate, billing, and program options that allow customers to adjust their usage to save money or participate in cost saving programs, using their devices. AMI and FAN also will improve our existing customer portal (MyAccount) information to provide more personalized insights to help customers understand how and where energy is being used and provide ways to help them save money.

However, fundamentally we must replace our present Automated Meter Reading (AMR) system. While it has delivered substantial value for customers since it was implemented in the mid-1990s, our vendor has announced that the technology will no longer be supported after the early-2020s – and they plan to discontinue support for AMR technology entirely in the mid-2020s. At the same time, the AMI technology and market have matured, which has driven many other vendors to also discontinue support of AMR. According to the U.S. Energy Information Administration, AMI adoption surpassed AMR in 2012, and the gap has widened as AMR rollouts have flattened.

We expect three primary outcomes from our deployment of advanced grid infrastructure and advanced technologies: (1) a transformed customer experience, (2) improved core operations, and (3) facilitation of future capabilities.

Transformed customer experience. Advanced grid investments combine to provide greater visibility and insight into customer consumption and behavior. We will utilize this information to transform the customer experience through new programs and service offerings, engaging digital experiences, enhanced billing and rate options, and timely outage communications. These options will provide customers greater convenience and control to save money, access to rates and billing options that suit their budgets and lifestyles, and more personalized and actionable communications. We expect our

early initiatives will focus on the execution of services that benefit all customers. Other customer choice programs enabled or enhanced by advanced grid initiatives may include smart thermostats, home area networks, rooftop solar, community solar gardens, optimized EV charging, and other DER offerings.

Improved core operations and capabilities. We also will improve our core operations, making investments to more efficiently and effectively deliver the safe and reliable electricity that our customers expect. While we have historically provided reliable service, we need to continue to invest in new technologies to maintain our performance in the top third of U.S. utilities, particularly as we deliver power from more diverse and distributed resources, and as industry standards continue to improve.[23] Our advanced grid investments provide technologies to manage the complexities of a more dynamic electric grid through additional monitoring, control, analytics, and automation. This will benefit customers through less frequent, shorter, and less impactful outages; more effective communication from the Company when they are impacted by an outage; and reduced costs from our more efficient use and management of assets.

Facilitation of future capabilities. Designing for interoperability enables a cost-effective approach to technology investments and means we are able to extend our communications to more grid technologies, customer devices, and third-party systems in a stepwise fashion, which unlocks new offerings and benefits that build on one another. This building-block approach, starting with the foundational systems, is in alignment with industry standards and frameworks (such as the Department of Energy's Next Generation Distribution Platform (DSPx) framework).[24] It also allows us to sequence the investments to yield the greatest near- and long-term customer value while preserving the flexibility to adapt to the evolving customer and technology landscape. By adhering to industry standards and designing for interoperability, we are well positioned to adapt to these changes as the needs of our customers and grid evolve.

Adherence to industry standards also allows us to better secure the grid and the devices we have connected to it. The increasing number of interfaces associated with grid modernization increases our cybersecurity exposure. As we move forward into the next generation of intelligent, interactive electric distribution, every facet of the electric network must be evaluated for cybersecurity risk. All aspects of the advanced grid must be inventoried, securely configured, and monitored regularly and

[23] See Leading the Energy Future 2017 Corporate Responsibility Report, Page 85, Xcel Energy (May 2018).
[24] See Modern Distribution Grid, Volume III: Decision Guide, U.S. Department of Energy Office of Electricity Delivery and Energy Reliability (June 2017).

thoroughly.

These investments also will produce a wealth of customer and grid data, which will, in turn, enable us to provide the new services described here and enhance existing services. These data-related efforts have begun, and next steps will include identifying the analytics capabilities needed to add additional value to customer offerings or improve utility operations. Data analytics in the utility industry continues to mature, so as grid modernization investments are deployed, these capabilities will evolve as well.

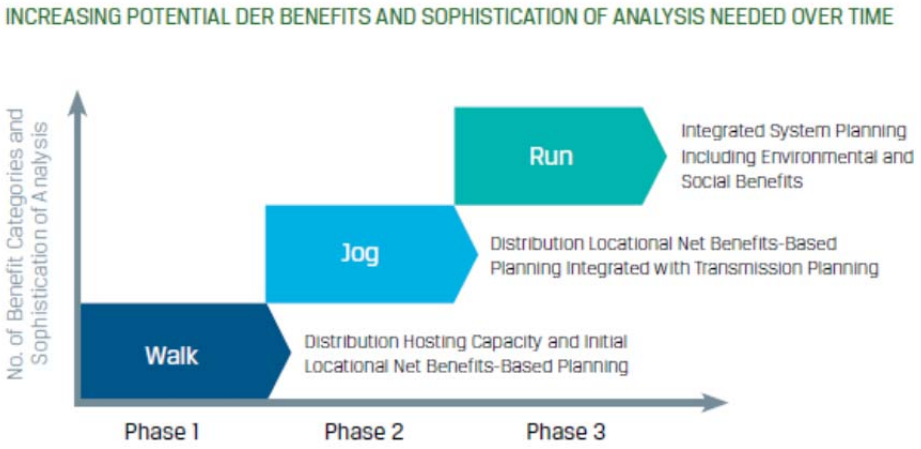
E. Transmission and Distribution Planning are Becoming More Interrelated

Although increasing DER penetration levels will drive integrated resource planning and distribution planning closer together, there are fundamental differences in how these two planning activities assess and develop plans to meet customers' needs. Distribution planning, like Integrated Resource Planning (IRP), charts a path to meet customers' energy and capacity needs, but is more immediate and subject to emergent circumstances because distribution is the connection with customers. Unlike IRPs, five-year plans are considered long-term in a distribution context; and, IRPs are concerned with size, type, and timing, whereas the primary focus of distribution planning is location. Thus distribution loads and resources are evaluated for each major segment of the system – on a feeder and substation-transformer basis – rather than in aggregate, like occurs with an IRP. Before a greater integration of distribution planning, transmission planning, and IRP can occur, distribution planning will need to become even more granular than it is today to address the challenges – and harness the benefits – of DER.

Today, the distribution and transmission planning groups work together as their respective planning processes impact or rely on one another. For example, distribution planning supplies transmission planning with substation load forecasts that are an input into the transmission planning process. These two groups also interact when distribution planning identifies the need for additional electrical supply to the distribution system – and similarly with interconnections, distribution is on point, and involves the appropriate planning resource as needed. The work that we are doing now on customer adoption-based of DER and electrification is helping to bring these planning processes closer together – and we believe will result in better informed sensitivities to ultimately inform both IRP and IDP. However, there are fundamental differences in these planning processes that will continue to challenge integration, at least in the near-term.

Minnesota is among a few states, including California, New York, and Hawaii, on the forefront of advancing its distribution planning as part of its grid modernization efforts. However, each is driven by differing policies and considerations; each is taking a different approach; and, each may result in its own solution that may not fit the circumstances elsewhere. While there are no definitive answers at this point, experts generally agree that a deliberate, staged approach to increased sophistication in planning analyses – commonly referred to as "walk, jog, run" – is important. The below Figure illustrates he stages below.

Figure 6: Staged Approach to Enhanced Planning Analyses



(*Source*: ICF White Paper, *The Value in Distributed Energy: It's all About Location, Location, Location* by Steve Fine, Paul De Martini, Samir Succar, and Matt Robison.

Movement from one stage to another is generally driven by growth in volume and diversity of distribution-connected, DER, the level of evolution of supporting planning practices and tools, and integration with other planning efforts, such as transmission, or resource planning.

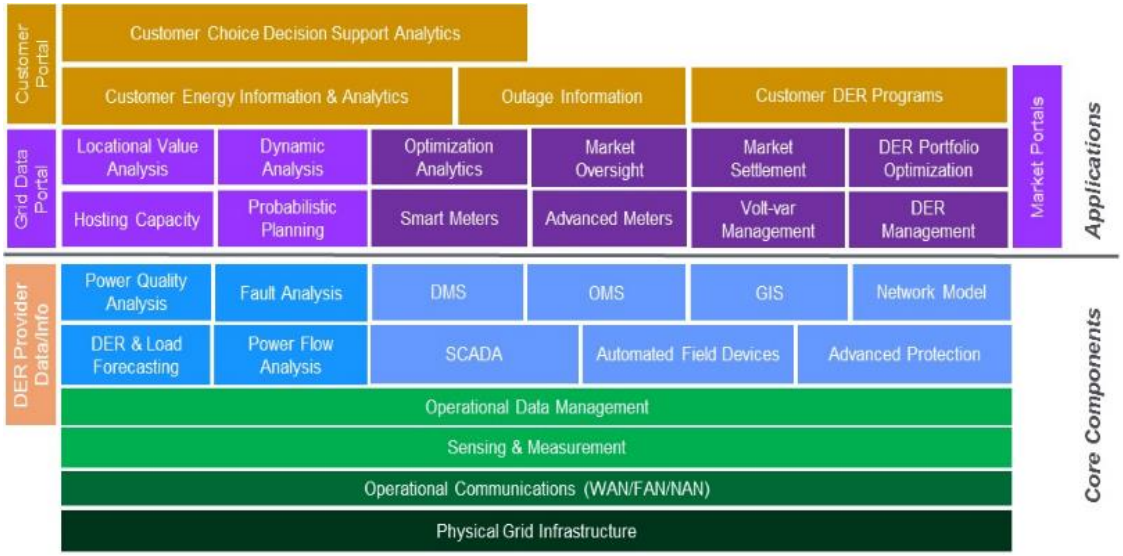
Similarly, the Berkeley Lab report, *Distribution Systems in a High Distributed Energy Resources Future, Planning, Market Design, Operation and Oversight* proposes a three-stage evolutionary structure for characterizing current and future state DER growth, with stages defined by the volume and diversity of DER penetration – plus the regulatory, market and contractual framework in which DERs can provide products and services to the distribution utility, end-use customers and potentially each other.[25] The report emphasizes the need to ensure reliable, safe and efficient operation of the physical electric system, DERs and the bulk electric system, which correlates to Minnesota utility requirements under Minn. Stat. § 216B.04 to furnish safe, adequate, efficient,

[25] Future Electric Utility Regulation series (Report No. 2), by Paul De Martini and Lorenzo Kristov (October 2015). *See* https://emp.lbl.gov/publications/distribution-systems-high-distributed

and reasonable service. The report describes Stage 1 as having low adoption of DERs, where the focus is on new planning studies when DER expansion is anticipated, which also correlates to where we are in Minnesota presently.

The U.S. Department of Energy (DOE), as part of its collaboration with state commissions and industry to define grid modernization in the context of states' policies is developing a guide for modern grid implementation that similarly recognizes foundational elements upon which increased utility tools and information and changes in infrastructure planning, grid operations, energy markets, regulatory frameworks, ratemaking, and utility business models rest, as shown in the below Figure.

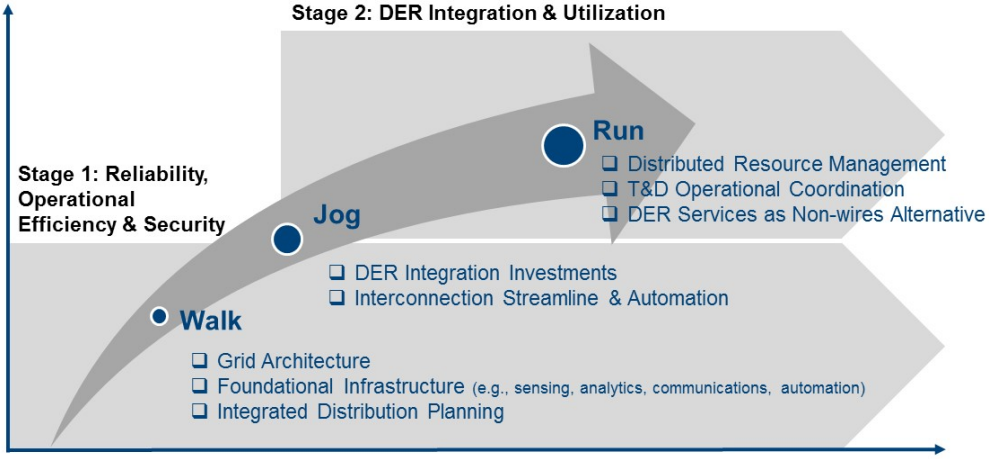
Figure 7: Platform Considerations



Source: *Considerations for a Modern Distribution Grid*, Pacific Coat Inter-Staff Collaboration Summit by DOE Office of Electricity Delivery & Energy Reliability (May 24, 2017).

The DOE's efforts also recognize timing and pace considerations, as shown in Figure 8 below.

Figure 8: Timing and Pace Considerations



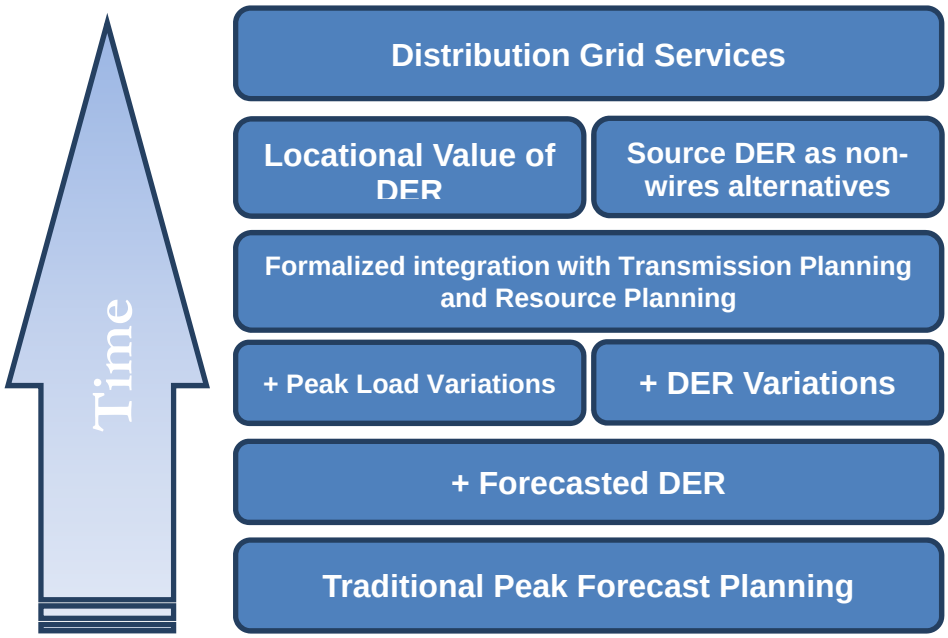
Source: *Considerations for a Modern Distribution Grid*, Pacific Coast Inter-Staff Collaboration Summit by DOE Office of Electricity Delivery & Energy Reliability (May 24, 2017).

As part of the May 24, 2017 Pacific Coast Inter-Staff Collaboration Summit, DOE observed that the U.S. distribution system is currently in Stage 1, with the issue being whether and how fast to transition to Stage 2. Underlying this question however, is the issue of identifying customer needs and state policy objectives – with a goal to implement proportionally to customer value – all of which will differ significantly across states. We agree that Minnesota is in Stage 1. We are focused on foundational infrastructure and starting to evolve our planning tools to enable integrated distribution planning.

A potential progression in planning practices could involve the evolution shown in Figure 9 below, with the drivers of progress being:

- Customer value, such as need, public policy, and cost/benefit,
- Utility readiness, including proper foundational tools and systems, and
- Supporting regulatory frameworks that address cost recovery, and any changes in federal or state market operations, etc.

Figure 9: Potential Evolution in Planning Practices



We expect this progression will need to occur over time as tools improve, policy drivers become clear, and customer value is determined.

Evolving distribution planning to be more like integrated resource planning will need to be thoughtful and planful. Today, IRPs are grounded in Minnesota statutes and rules – and chart a long-term direction of how load can be served in a broad service area. The IRP process is grounded in Minn. R. 7843, which prescribes the purpose and scope, filing requirements and procedures, content, the Commission's review of resource plans, and plans' relationship to other Commission processes, including certificates of need and the potential for contested case proceedings.[26] These processes work for IRPs due to the long-term nature of macro resource additions and changes.

However, distribution planning is more immediate; its full planning horizon correlates to the five-year action plan period of an IRP, which is generally a continuation of past

[26] Minn. R. 7843.0500, subp. 3 prescribes the factors for the Commission to consider in reviewing IRPs. "The Commission shall consider the characteristics of the available resource options and of the proposed plan as a whole. Resource options and resource plans must be evaluated on their ability to: maintain or improve the adequacy and reliability of utility service; keep the customers' bills and the utility's rates as low as practicable, given regulatory and other constraints; minimize adverse socioeconomic effects and adverse effects upon the environment; enhance the utility's ability to respond to changes in the financial, social, and technological factors affecting its operations; and limit the risk of adverse effects on the utility and its customers from financial, social, and technological factors that the utility cannot control."

IRPs. Distribution systems are utilities' point of connection for customers. While an unexpected loss of a macro system component, such as a power plant, can often be covered by the MISO system without interruption of power to customers, loss of a distribution system component often results in a power outage to the customers it was serving. While there is some redundancy in the system to avoid this circumstance, the types of issues addressed by distribution planning are typically much more immediate than IRPs – and do not have a back-up like MISO. Therefore, evolving distribution planning practices will need to be thoughtful – and ensure the focus remains on the immediacy of customer reliability.

While the timeline remains uncertain, it is clear that the distribution grid of the future will look and perform differently than it has over the past 100+ years. Minnesota is in the forefront on the issue of advancing its distribution planning practices with other leaders such as California, New York, and Hawaii. Lessons learned from these states that Paul De Martini, ICF International, shared as part of his presentation at the Commission's October 24, 2016 grid modernization distribution planning workshop included:

- Changes to distribution planning should proactively align with state policy objectives and pace of customer DER adoption.
- Define clear planning objectives, expected outcomes and regulatory oversight – avoid micromanaging the engineering methods.
- Define the level of transparency required for distribution planning process, assumptions and results.
- Engage utilities and stakeholders to redefine planning processes and identify needed enhancements.
- Stage implementation in a walk, jog, run manner to logically increase the complexity, scope, and scale as desired.

No one state has yet figured out the progression of distributing planning enhancements; each is taking a different approach to address the complexities inherent in implementing changes at the right pace and that is proportional to both customer and grid needs – and that realizes net value and benefits for all customers. While the national perspective and other state actions provide helpful points of reference, Minnesota has long been a leader in developing supportive regulatory frameworks to align achievement of policy objectives with business objectives. The increasing complexity of our industry requires a rethinking of the current framework to ensure it is still aligned.

We support the evolution of the grid, and are taking actions to evolve our planning tools and improve our foundational capabilities to support our customers' expanding energy needs and expectations. We support a shift toward more integrated system planning, where utilities assess opportunities to reduce peak demand using DER and to supply customers' energy needs from a mix of centralized and distributed generation resources. However, at a measured pace that correlates to Minnesota policy objectives and customer value.

We are currently evaluating our existing planning processes and tools to determine how to better align and integrate the distribution, transmission, and resource planning processes in the future. Fundamentally, they are rooted in contradictory planning paradigms – with resource planning concerned with size, type, and timing, distribution concerned with location, and transmission somewhere in between. In the near term, we are using the same customer adoption-based DER forecasts and electrification in the IRP and the IDP to the extent practicable – with the IRP having the ability to consider sensitivities. As these planning processes continue to evolve together, it will allow greater ability to consider more potential outcomes – and think about how we can design an optimal portfolio of resources that best meets our overall customer load needs under a range of potential outcomes.

III. CONCLUSION

Our transmission and distribution systems are critical to our ability to serve our customers in a reliable and safe manner, and to deliver growing choice and increasing renewable energy. As we actively prepare our distribution system for the needs of the future, we consider the need for thoughtful investments to meet our core obligation, safely and reliably deliver energy to our customers, and adopt smarter technologies to further enable DER on our system. We recognize and will continue to respond to customer interest in increased DER.

The transmission grid is also facing new challenges and opportunities as traditional baseload units retire, large scale renewables significantly increase, and DER are increasingly adopted. In some cases, such as increasing consideration of distribution-level DER on the transmission grid, changes in the market and planning constructs are underway. Other changes are just coming into view and the planning constructs have not yet caught-up. Overall, we envision building toward an integrated grid in the future that supports the Company's clean energy transition – leveraging the strength of an interconnected system to make the best use of available resources and continue to serve our customers with resilient and reliable power.

APPENDIX J1 – XCEL ENERGY BASELOAD STUDY

I. INTRODUCTION

In our last Resource Plan, we discussed the rapid evolution of our industry due to changing technology, enhanced customer expectations, and the increasing consensus around the importance of carbon reduction. In that plan, we described our vision of an energy future that transitions our generation fleet such that we will achieve a dramatic reduction in carbon. We explained that taking action now to transition our fleet mitigates the costs and risks of retiring a significant proportion of our baseload generation in the same time period. We specifically proposed to accelerate our transition away from coal by ceasing operation of our Sherburne County (Sherco) Units 1 and 2 in 2026 and 2023, respectively.

We provided robust technical analysis supporting our proposed retirement of those coal units, including Midcontinent Independent System Operator (MISO) preliminary retirement studies, a technical analysis that we performed in conjunction with Siemens Power Technologies, and an analysis of our Black Start Plan. We concluded that the most cost-effective way to mitigate technical issues resulting from the unit retirements and continue to meet our customers' load requirements would be to build an intermediate natural gas-fueled plant at the existing Sherco site. The Commission approved our proposed schedule to retire Sherco Units 1 and 2,[1] and found that more likely than not there will be a need for approximately 750 MW of intermediate capacity coinciding with the retirement of Sherco Unit 1 in 2026.[2]

The Commission also required further study of an orderly and cost-effective retirement of our remaining baseload units in our next Resource Plan, as follows:[3]

> In its next resource plan filing, Xcel shall… describe its plans and possible scenarios for cost-effective and orderly retirement of its aging baseload fleet, including Sherco, King, Monticello, and Prairie Island.

The Baseload Study we performed in support of this Resource Plan builds on the outcomes of our previous plan and includes industry insights, and technical and

[1] *See* In the Matter of Xcel Energy's 2016-2030 Integrated Resource Plan, ORDER APPROVING PLAN WITH MODIFICATIONS AND ESTABLISHING REQUIREMENTS FOR FUTURE RESOURCE PLAN FILINGS, Ordering Point No. 7, Docket No. E002/RP-15-21 (January 11, 2017).
[2] *Id.* at Ordering Point No. 8. While the Order also addressed next steps for the replacement generation at Sherco, legislation was passed as part of the 2017 Legislative Session that in summary, allows the Company to proceed with the construction of the replacement unit at Sherco in accordance with the parameters specified in the legislation, and without a certificate of need. [Laws of Minnesota 2017, chapter 5—H.F. No. 113, section 1]
[3] *Id.* at Ordering Point No. 14(a).

economic analyses of retirement of our Allen S. King plant, Sherco Unit 3, Monticello Nuclear, and Prairie Island Nuclear Units 1 and 2.

To understand the technical impacts of retiring one or more baseload generating units, we perform engineering analyses on simulations of the Unit changes that assess the results against established industry reliability and operating criteria. The studies use the best available information at the point in time that they were conducted. However, the grid is dynamic, and expected conditions will change when new generation comes online, existing generation retires, new transmission lines are constructed, or existing lines are reconfigured; in addition, reliability measurement criteria may change. The results therefore are a point-in-time representation of the technical issues we expect would occur in a studied scenario.

The Baseload Study we conducted is comprised of four primary components:

- **Midcontinent Integrated Systems Operator (MISO) Attachment Y2 preliminary retirement studies**, which assessed various single Unit and combined Unit retirement scenarios for thermal and voltage concerns,
- **Xcel Energy Transmission Reliability studies**, which examined system stability and response impacts associated with baseload generating resource changes on the NSP System and on neighboring systems,
- **Industry insights**, including the North American Electric Reliability Corporation (NERC) *Generator Retirement Scenario Special Study* and the MISO *Renewable Integration Impact Analysis* (RIIA), which provide important insights into the combined effects of baseload generator retirements in a region and grid impacts at increasing levels of renewables penetration, and
- **A focused Strategist analysis**, which examined the economic implications of various Unit and combined Unit retirements at different points in time.

The results of this Baseload Study informed the Preferred Plan we propose in this Resource Plan, which includes the following baseload actions: (1) Retire our remaining two coal units early – King in 2028 (nine years early) and Sherco 3 in 2030 (ten years early), and (2) Extend the operation of Monticello nuclear 10 years through a license extension, to 2040.

Other conclusions and insights from this Study include:

- The retirement of our current baseload units must be orderly, and will be impacted by decisions other MISO generation owners make regarding their baseload units.

- We must maintain sufficient firm dispatchable, load supporting resources to ensure customer reliability and to support integration of higher levels of renewable resources.
- Changes in the MISO planning construct are necessary to properly recognize the inherent variable and intermittent nature of renewable resources in meeting customer needs every hour of every day.
- Significant new regional transmission development will be necessary to support increased levels of renewable resources and to support the retirement of baseload units.
- From an economic perspective, the scenarios that included early coal retirements and nuclear extensions had the most favorable present value.

Insights gained from this Study also helped to inform our development of a Reliability Requirement (discussed in Appendix J2), which bridges the gap between current regional planning requirements and necessary changes to account for: (1) the variable contribution renewable resources provide to the system, (2) the lack of long-term regional system planning guidance for the expected contribution of renewable resources as penetration levels rise, and (3) the need for sufficient firm dispatchable, load supporting resources to reliably integrate increasing levels of renewable resources.

We believe the increasing trend toward a clean energy future, along with rapidly advancing technologies and aging generation assets will significantly change the generation mix in Minnesota and across the United States over the next 15-plus years. We have done a comprehensive analysis of the impacts of cost-effective and orderly retirement of our baseload fleet in compliance with the Commission's Order – and in support of our clean energy vision.

The plan we propose in this Resource Plan sets the NSP System on a trajectory to a clean energy future that will continue to power our customer's lives and possibilities with energy they can trust to be safe, reliable, affordable, and progressively clean. It also provides strategic flexibility to adjust as technologies continue to develop; as the industry collectively furthers its understanding of the impacts from the significant changes in the generation mix that are underway; and, while we and others ready the grid with increased transmission capabilities.

This Baseload Study is organized as follows:

I. Introduction
II. Grid Function, Design, and Attributes

III. The Grid is Evolving
IV. Xcel Energy Baseload Retirement Study
V. Summary and Conclusions

II. GRID FUNCTION, DESIGN, AND ATTRIBUTES

The electric "grid" is a large complex machine consisting of generation, transmission and distribution facilities that operate across a very large geographic area. The NSP System is part of MISO, which is part of the Eastern Interconnection that connects the generation and transmission assets of the electrical grids from the Rocky Mountains to the East Coast and from Canada to the Gulf of Mexico. This interconnected network of generating resources and transmission infrastructure works together to seamlessly respond and adjust to dynamic and sometimes adverse circumstances to provide an adequate and reliable supply of electricity to customers. Each resource and system component plays a unique role based on its size, type and location on the system – and because the grid is so integrated, generation changes made to one utility's system impact other portions of the system.

At its core, to preserve system stability and customer reliability, the system must balance generation with changing load conditions and fluctuations caused by other disturbances. Large generating units like our current baseload units afford the capability for the system to "ride through" these disturbances by virtue of their sheer mass. Without the inertia, or resistance to a change in state of motion, afforded by these large units, system stability could be compromised. Similarly, the frequency regulation of the transmission system is governed by the connected generating units. If system frequency deviates beyond allowable levels, protective devices will disconnect generation and/or customer load from the rest of the system. These disconnections can further exacerbate any imbalance between load and generation, which may cause cascading events.

A. Traditional Grid Function

Transmission, in its most basic sense is the connection between generation resources and the customer demand it is intended to serve. Because of that, the transmission system that we have today was traditionally meant to send power from large centralized power stations to the load centers utilizing high voltage transmission lines. These power stations were typically located by the areas of higher customer demand, which would minimize the amount of transmission needed to serve that demand. During the early electrification era, which made modern conveniences like electric lighting commonplace, each utility built, owned and operated their own generation resources and transmission systems meant to serve their customers.

During, and after this initial phase of electrification, growing customer demand for electricity was the primary driver for new, larger and more efficient generation resources and transmission sources meant to deliver that power. Demand growth was overall fairly steady, which allowed for effective long-term planning process to develop. Because of this predictability and the efficiencies found through economies of scale, most generation resources consisted of large coal, nuclear, or hydro facilities. Smaller, more nimble units were also utilized to supplement these large, centralized resources to meet the added stress of summer loads. Regional Coordination, and the "grid" as we know it today, was not a consideration for power companies at this time.

As these individual power companies began to identify efficiencies through coordination with other local power companies that could reduce costs, the full value the centralized power stations provided to the system was also realized. These large scale synchronous generation resources provided the backbone of the stable system we have today. The ability of these generators to provide the primary system support for adverse system conditions such as faults and loss of transmission elements, allowed for increased interconnection between local utilities and greater system reliability.

After the Northeast Blackout in 1965, the benefits of greater coordination, both locally and regionally, were recognized, and Power Pools were formed to share excess resources that each area had. To increase the ability of these resources to be shared amongst the Power Pool members, large bulk transmission facilities were developed to interconnect neighboring utilities and allow for large amounts of power to be transferred in emergencies. As a way to ensure these resources were not stretched too thin, Power Pools also set the amount of generation resources each company was required to keep in order to maintain adequate supply of power.

B. Grid Oversight and Evolution

As the initial phase of electrification was in full swing, the United States Congress established the Federal Power Commission (FPC) to coordinate the hydroelectric project under federal control. The Federal Power Act and Natural Gas Act, passed in 1935 and 1938 respectively, granted the FPC the power to regulate the sale and transportation of electricity and natural gas across state lines. Because of the chronic brownouts of the 1960's and the OPEC embargo in the 1970's, the FPC was reorganized and designated as the Federal Energy Regulatory Commission to oversee federal energy policy and the deregulation of the natural gas industry. The first FERC Order directed specifically at the restructuring of the electric industry was issued in 1996 as Order No. 888. Known as the Open Access Order, the intention of Order

888 was to ensure open and non-discriminatory access to the electric transmission system and encouraged the development of Price Exchanges to increase transparency in energy clearing prices.

Order 888 was followed shortly after by Order 889 to require the posting of transmission availability on a public bulletin board, referred to as the Open Access Same-Time Information System, or OASIS. The issuance of these Orders led to the development of Independent System Operators (ISOs) to facilitate the new requirements, in large part for existing Power Pools, set in place by Orders 888 and 889. In 1999, FERC issued Order 2000, which encouraged participation in Regional Transmission Organizations (RTOs) with the expectation that these RTOs would establish whole electricity markets to enable efficient use of the available resources and transmission system.

1. The Energy Policy Act of 2005 Created the Present FERC

The last major development, which led to the FERC we know today, was the passing of the Energy Policy Act of 2005, which greatly increased the authority FERC had over the jurisdictional entities across the country. This included the enforcement of transmission system reliability standards, the ability to levy fines for non-compliance, and other increased authorities. Today, FERC regulates interstate transmission of electricity, natural gas, and oil. Since the passing of the Energy Policy Act of 2005, FERC has issued several major orders to ensure the planning of the most efficient and cost effective transmission system possible through long-term planning requirements as well as ensuring the fair and non-discriminatory operation of wholesale electricity markets across the country.

2. NERC Oversees and Enforces Grid Reliability

NERC, created through FERC's increased authority under the Energy Policy Act of 2005, is a non-profit entity that oversees the eight regional reliability systems that stretch from Canada to Mexico. NERC is designated by the FERC as the Electric Reliability Organization, which is the independent entity that develops and enforces mandatory standards for the reliable operation and planning of the bulk electric system (BES) throughout North America. NERC's primary responsibility is to develop power system standards, the monitoring and enforcement of those standards, and ensure power system operators are qualified through training.[4] Analysis of BES impacts from new generation and transmission facilities and changes to existing generation or transmission facilities are measured against NERC standards and

[44] NERC is also responsible for investigating power system outages that have a significant impact.

requirements. We provide an abbreviated outline of NERC Event Category definitions below:

Table 1: Abbreviated List of NERC Event Category Definitions[5]

P1	Single Contingency – Loss of one of the following: * Generator * Transmission Circuit * Shunt Device * Transformer * Single Pole of a DC line
P2	Single Contingency – * Opening of a line section w/o a fault * Internal Breaker fault (non-Bus-tie-Breaker) * Bus Section fault * Internal Breaker Fault (bus-tie Breaker)
P3	Multiple Contingency – Loss of one of the following: * Generator * Shunt Device * Transmission circuit * Single pole of a DC line * Transformer
P4	Multiple Contingency – (*Fault plus stuck breaker*) Loss of multiple elements caused by a stuck breaker (non-Bus-tie Breaker) attempting to clear a Fault on one of the following: * Generator * Bus Section * Transmission Circuit * Loss of multiple elements caused by a stuck breaker (Bus-tie * Transformer Breaker) attempting to clear a Fault on the associated bus * Shunt Device
P5	Multiple Contingency (*Fault plus relay failure to operate)* – Delayed Fault Clearing due to the failure of a non-redundant relay protecting the Faulted element to operate as designed, for one of the following: * Generator * Shunt Device * Transmission Circuit * Bus Section * Transformer
P6	Multiple Contingency (*two overlapping single contingencies)* – Loss of one of the following: * Transmission Circuit * Shunt Device * Transformer * Single pole of a DC line
P7	Multiple Contingency (*Common Structure)* – The loss of: * Any two adjacent (vertically or horizontally) circuits on common structure * Loss of a bipolar DC line

NERC additionally authorizes regional entities, which in the Upper Midwest is the Midwest Reliability Organization (MRO). The MRO is a regional entity spanning from Manitoba and Saskatchewan Canada through the United States Midwest. The MRO is primarily tasked with ensuring compliance with reliability standards for the BES. The MRO conducts individual company assessments for any possible areas of improvement or violations.

[5] For a full description of NERC's event categories, *please see*: http://www.nerc.com/pa/Stand/Reliability%20Standards/TPL-001-4.pdf beginning at page 8.

3. Midcontinent Independent System Operator

The first regional transmission organization to obtain approval by FERC was the Midwest (now Midcontinent) Independent System Operator (MISO); MISO is the ISO for the Upper Midwest. MISO is an independent, not-for-profit company authorized by FERC to provide open-access transmission service, operate the transmission grid, administrate a wholesale energy market, and perform regional transmission planning in 15 states throughout the Midwest, southern United States, and Manitoba, Canada.[6] The Xcel Energy operating companies that comprise the NSP System (Northern States Power Company-Minnesota and Northern States Power Company-Wisconsin) are signatories to the MISO Transmission Owners Agreement and are therefore members of MISO and thus subject to MISO Tariffs and requirements.

MISO's primary function is to ensure open and fair access to the transmission system. In addition, MISO administers the wholesale energy market for the same region.

C. Grid Basics

In this section, we provide an overview of the NSP System, factors effecting reliability, and the role played by baseload generating resources on our system.

1. NSP System Transmission Overview

The Twin Cities metro area is surrounded by a double circuit 345 kV *bulk* transmission system that extends from Benton County in the north, east to Chisago County, south to Dakota County, west to Scott County, and back north to Becker, Minnesota. This 600 mile ring of 345 kV lines encompassing nearly 1,300 square miles forms the backbone of the bulk transmission system feeding the Twin Cities load center. This 345 kV ring is connected through several bulk 345 kV lines tying to our neighboring utilities, and a 500 kV bulk transmission line to Manitoba Hydro in the north. These tie-lines connect the Twin Cities load center to the MISO generation market and the Eastern Interconnection – providing important "back-up," should there be an unexpected event that requires the Company to rely on the grid to maintain reliability for our customers.

[6] Independent System Operators grew out of FERC Orders Nos. 888/889 where FERC suggested the concept of an Independent System Operator as one way for existing tight power pools to satisfy the requirement of providing non-discriminatory access to transmission. Subsequently, in Order No. 2000, FERC encouraged the voluntary formation of Regional Transmission Organizations to administer the transmission grid on a regional basis throughout North America (including Canada).

The 345 kV ring that surrounds the Twin Cities feeds the underlying Twin Cities 115 kV transmission grid, which connects to our low voltage distribution system that delivers the power directly to businesses, houses and other loads. The transmission system and the lower voltage distribution system in the Twin Cities area has developed over the past 100 years to serve the growing area, and is constantly being analyzed and updated to ensure optimal and reliable power delivery.

Our BES is currently anchored at the corners by several large coal and nuclear generators that act as the baseload generation for the NSP System. They include Sherco and Monticello in the northwest, and King and Prairie Island in the east and southeast. Together these plants provide over 4,350 MW of capacity[7] and over 29,000 GWh of energy to our customers, which represents 47 percent of the NSP System accredited generating capacity and 65 percent of the system energy.[8] This generation is supplemented by several natural gas generating plants located on the 115 kV system in the Twin Cities. These generating units include Riverside, Highbridge, Black Dog, and Blue Lake.

The 500 kV line that ties into Chisago County substation in the northeast connects the hydro power produced by Manitoba Hydro to the Twin Cities load center. A significant proportion of our wind power is located in southwest Minnesota and is tied into the Twin Cities through a number of lines developed over a period of years to connect the wind-rich areas in southwest Minnesota and South Dakota to the Twin Cities load center. A robust transmission system such as this facilitates the provision of reliable, low cost power to our customers from a diverse mix of generation resources, and mitigates risk from catastrophic events.

The existing grid is a valuable asset and an enabler that has and will continue to support the evolution and growth of our system. The grid has facilitated integration of substantial wind generation onto the NSP System by absorbing the inherent fluctuations of this variable generation type over a large area. Transmission enables the transfer of wind and solar and other types of generation from where it is most effectively located to customer load located elsewhere where it can be utilized to the fullest extent.

2. A Reliable Grid Must Weather Unexpected Failures and Events

NERC defines a reliable BES as one that is able to meet the electricity needs of end-use customers even when unexpected equipment failures or other factors reduce the

[7] Nameplate capacity ratings.
[8] MISO accredited capacity values.

amount of available electricity, and divides reliability into two categories:[9]

- *Adequacy*. Adequacy means having sufficient resources to provide customers with a continuous supply of electricity at the proper voltage and frequency, virtually all of the time. Maintaining adequacy requires system operators and planners to take into account scheduled and reasonably expected unscheduled outages of equipment, while maintaining a constant balance between supply and demand.
- *Security*. For decades, NERC and the bulk power industry defined system security as the ability of the bulk-power system to withstand sudden, unexpected disturbances, such as short circuits or unanticipated loss of system elements due to natural causes. In today's world, the security focus of NERC and the industry has expanded to include withstanding disturbances caused by manmade physical or cyber-attacks. The BES must be planned, designed, built and operated in a manner that takes into account these modern threats, as well as more traditional risks to security.

Electrical system reliability can be defined as the ability of the electrical grid, which includes transmission, generation, distribution and related components, to serve customer load under any system condition. Maintaining a reliable electricity supply for customers requires that generation, load and electrical losses balance – and maintain a 60 Hz frequency. If the frequency varies only one or two tenths of a hertz from 60 Hz, it can cause damage to equipment, and automated protection schemes will disconnect pieces of the grid to avoid damaging equipment.

A strong transmission system improves the reliability of the electric power system, and facilitates a diverse and low cost resource portfolio for customers – allowing lower cost resources with diverse fuel types, and resource types not available in the immediate area to be efficiently transported to serve their needs. For example, wind resources need to be constructed where the wind is strongest and most consistent; large-scale solar resources where there is sufficient land and the most consistent sunshine – both of which are generally away from large population centers. A robust transmission system brings together varied generating units – some built to run continually, others only to run at peak times when they are most needed, and renewable resources on an intermittent basis – together into an integrated grid.

The system must also be able to facilitate both "active" and "reactive" power, which are typically produced by non-renewable generating unit types. Active power, measured in watts, is the form of electricity that powers equipment. Reactive power,

[9] http://www.nerc.com/AboutNERC/Documents/NERC%20FAQs%20AUG13.pdf

measured in volt-amperes reactive (VARs), is the energy supplied to create or be stored in electric or magnetic fields in and around electrical equipment. Reactive power is particularly important for equipment that relies on magnetic fields for the production of induced electric currents (e.g., motors, transformers, pumps and air conditioning). Reactive power can be transmitted only over relatively short distances, and thus must be supplied as needed from nearby generators. If reactive power cannot be supplied promptly and in sufficient quantity, voltages deteriorate and, in extreme cases, can result in a voltage collapse.

The grid must also be able to adjust to changing customer loads, the availability of diverse resources, and have sufficient redundancy built-in, making it capable to withstand the failure of its most critical lines, generators, or other components. As customer load changes over the course of a day, generation must change to accommodate the load at any given time. With the high penetration of renewables on the NSP System, we must ensure that we have adequate firm dispatchable, load supporting generation to both accommodate the load and whatever generation mix we have at each point in time. We must also maintain a spinning reserve – generation that is available at a moment's notice – to account for the largest contingency in the area.[10] Having large coal generating units has helped, because they have the ability to be "turned up" and "turned down" based on the level of renewable generation being delivered to the system at any given time. With our proposed plan to retire the remaining coal units on the NSP System, other load supporting generating resources will be needed to perform these important reliability functions.

3. Role of Baseload Generating Resources

As we have discussed, the ability to provide reliable electric service depends on a complex and interconnected network of generating resources and transmission infrastructure that provides capacity and delivers energy to customers. Each resource and system component in the network plays a unique role based on its size, type and location on the system. In fact, the Upper Midwest grid and the NSP System has been designed around the current baseload units, and relies on the unique aspects of these units to not only generate capacity and energy for our customers, but also to provide numerous essential system operational services.

When analyzing the impacts of ceasing operations at one of our existing coal or nuclear units, it is important to consider these operating and technical characteristics beyond just the unit's energy output. These include:

[10] Spinning Reserve is unloaded operating capacity available on units connected to and synchronized with the interconnected electric system and ready to take load immediately in response to a frequency deviation.

- *Power Deliverability.* The existing transmission system has been developed to be able to receive the approximately 2,400 MW of power injected from Sherco,[11] 671 MW injected from Monticello, 598 MW injected from King, and 1,150 MW injected from Prairie Island and to deliver it to various area substations to meet the electrical power demands of customers.[12] This power deliverability capability is often referred to as "transfer capability" or "thermal limits" of the system. Transmission systems are made capable of receiving and moving power from specific generators at specific locations; changing generator characteristics or locations requires corresponding changes to grid capabilities.

- *Dynamic Stability.* The transmission grid is a vast interconnected machine with many parts. There are a mix of large and small gears in this machine, all spinning at the same rate (i.e. synchronous), simultaneously producing and delivering electricity to customers. Generating units are the spinning gears in this machine. Large generators like Sherco Unit 3 and King have large spinning shafts that provide a strong backbone for the machine's operation. With enough of these big "gears" spinning, the machine can stay electrically stable and continue operating without interruption when small gears drop in and out of operation (like when the wind stops blowing or sun stops shining), or when another big gear drops out, or a "contingency," happens to some part of the machine. These large gears are also more likely to stay connected to the grid during a contingency than the small gears because large rotating masses have more inertia and are therefore not as easily jarred, or disrupted by a disturbance. Having the large gears in place also enables more small gears to be connected to the machine because they don't have as much impact with the large gears in place. The large generating units thus provide "dynamic stability" to the grid.

- *Fault Current.* Large synchronous generating units provide "fault current," which is necessary for the system protection equipment to function properly. If the system has too little fault current, it is difficult for system protection systems to differentiate customer load from an electric fault, which could cause the protection system to not function properly.[13] The protection system is the overarching electrical monitoring scheme that assesses the real time condition of the transmission grid and acts to prevent damage to system components and prevent cascading failures. The large generating units operating today are important sources of fault current, and the protection

[11] Nameplate capacity ratings of entire site. SMMPA owns 41% of Unit 3 (approximately 380 MW).
[12] Nameplate capacity ratings.
[13] For example, the protective equipment could misinterpret the load as a fault, and de-energize an unfaulted circuit.

system and existing deployed assets rely on sufficient fault current for the protection system and other electrical facilities to work as designed. Many of the electric devices that are deployed on the grid and in service today, such as wind generators and other assets, are engineered and designed to function properly with the amount of fault current that has been historically available on the grid. Therefore, changing the amount of fault current on the grid could not only impact protection systems, but could also impact other electric assets.

- *Black Start Capability.* In the event of a major regional grid outage, firm dispatchable generating units with a secure fuel source are an integral resource to restoring power to the electrical grid, or "restarting the machine." Only firm dispatchable generating units of a certain size that are capable of creating and absorbing reactive power are eligible to perform black start functions. Once Sherco Units 1 and 2 retire, the Sherco Combined Cycle (CC) will be an important part of our black start plan. Renewable generation, such as solar and wind are not currently considered eligible Target Units due to their inherent intermittent nature, and their inability to provide or absorb reactive power. A large battery energy storage system can be configured to be technically capable of providing black start service, likely as part of a relatively small Initial Black Start Unit. However, they may not yet be economically viable for this purpose. There are also technical concerns with regard to how batteries can absorb reactive power, which would be needed if the battery was not paired with another type of generation asset.

- *Voltage Support.* The real time conditions on the transmission system are constantly changing and require ongoing adjustments to maintain voltages at required levels. Large synchronous power sources like our current baseload units, provide significant system voltage support along with necessary "reactive power." Reactive power is required to start and run motors, like in air conditioners and industrial equipment (called "inductive loads"). Large population centers generally require large generating units located reasonably nearby to support system voltage effectively. As in the dynamic stability discussion, without enough large units in place, the machine isn't as capable and robust when it runs.

- *System Regulation.* System regulation essentially means the ability of the system to respond to changes in usage, i.e. keeping the generators and loads matched at all times. Combined cycle generating units have the electrical characteristics to provide this fast response balancing in real time. The system frequency, required to be maintained at 60 Hz in the US grid, is an active measure of this balance. When there are changes to the generation/load balance, as when wind speeds drop or a large industrial load comes online, the frequency drops if

there is insufficient regulation capability on the system. This is another aspect of the dynamic stability of the system, typically in a longer timeframe.

The National Academies of Sciences, Engineering, and Medicine observed that large-scale interconnected generating units have two significant advantages:

(1) *Reliability*. By interconnecting hundreds or thousands of large generators in a network of high-voltage transmission lines, the failure of a single generator or transmission line is usually inconsequential, and

(2) *Economics*. By being part of an interconnected grid, electric utilities can take advantage of variations in the electric load levels and differing generation costs to buy and sell electricity across the interconnect. This provides incentive to operate the transmission grid so as to maximize the amount of electric power that can be transmitted.

However, large interconnections also have the undesirable side effect that problems in one part of the grid can rapidly propagate across a wide region, resulting in the potential for large-scale blackouts such as occurred in the Eastern Interconnection on August 14, 2003. Hence there is a need to optimally plan and operate what amounts to a giant electric circuit so as to maximize the benefits while minimizing the risks.[14]

D. Planning Overview

The MISO long-term planning process, defined in Attachment FF to the MISO Tariff, is an eighteen month, overlapping process through which annual transmission expansion plans are developed and approved. This process is made up of three distinct long term planning efforts: Reliability Planning, Economic Planning and Resource Adequacy. MISO has recognized that its present planning processes require update to recognize the increasing levels of renewable resources on the grid, as well as increasing levels of energy efficiency, demand response, and distributed energy resources (DER). We discuss this further in Part III below.

1. Reliability Planning

As a NERC registered Transmission Planner, the Company works jointly with MISO and neighboring utilities to develop long term transmission plan to ensure a reliable transmission system. This is accomplished through several local and regional planning efforts, as follows:

[14] National Academies of Sciences, Engineering, and Medicine 2016. *Analytic Research Foundations for the Next-Generation Electric Grid*. Washington, DC: The National Academies Press, page 10. https://doi.org/10.17226/21919

Biennial Transmission Projects Report. In compliance with Minn. Stat. § 216B.2425, the Company participates in the Biennial Transmission Project Report efforts with other Transmission Owners. Starting in 2001, this effort completed its ninth iteration with the 2017 report. In 2003, the Minnesota Public Utilities Commission established six transmission planning zones across the state in 2003. Those six transmission planning zones are the Northwest Zone, the Northeast Zone, the West Central Zone, the Twin Cities Zone, the Southwest Zone, and the Southeast Zone. The Biennial Report identifies the present and reasonably foreseeable transmission "inadequacies" in the transmission system that exist in each of these six transmission planning zones. With information about each inadequacy identified provided. The Biennial Report also provides an update on the status of the utilities' efforts to meet state Renewable Energy Standard deadlines. We summarize our most recent Biennial Report in Appendix I: Supporting Infrastructure: Transmission & Distribution.

NERC Transmission Planner Registration. To satisfy the obligations associated with the Transmission Planner registration with NERC, the Company also participates in the annual Minnesota Transmission Assessment and Compliance Team (MNTACT) to perform annual long-term transmission planning studies in accordance with federal, state and local transmission reliability standards and criteria. The Company utilizes the results of these analyses to inform the regional planning efforts undertaken by MISO.

MISO Membership and FERC Order Obligations. In accordance with the obligations of MISO membership and FERC Orders 890 and 1000, the Company also participates in regional long-term planning efforts facilitated by MISO. While these efforts replicate work already undertaken by the Company in other planning efforts, participation in MISO reliability planning process provides an open and transparent planning process that allows input and discussion amongst a wide range of stakeholder and public advocacy groups. Based on the requirements of the MISO Transmission Owners agreement, MISO approval is also required for inclusion of new transmission facilities under MISO's functional control.

2. Economic Planning

In addition to the long-term transmission reliability analyses, participation in the MISO planning processes also includes an annual economic-based planning analysis to identify inefficiencies in the transmission system leading to less than ideal wholesale electricity market dispatch. Starting with a stakeholder-approved set of wide-ranging future scenarios, this analysis first identifies these areas of system inefficiencies – after

which, stakeholder submitted solutions are analyzed to determine if there is a cost effective solution. The Huntley–Wilmarth 345 kV Project is an example of a cost effective solution analyzed to develop the most cost-effective market possible.[15]

3. Resource Adequacy

The Resource Adequacy process facilitated through the MISO process is designed to ensure enough capacity is available to meet the needs of all consumers in the MISO footprint during all time frames and at just, reasonable rates. Although the responsibility for resource adequacy, MISO's process provides support in their members individual resource adequacy efforts and provide forums to increase transparency into these more localized efforts. These support efforts include calculation of the Planning Reserve Margin, which defines the level of reserve generation capacity needed to ensure an adequacy supply of energy based on probabilistic analyses. Also facilitated in this process is the Deliverables to the Planning Resource Auction, including peak forecasted demand and Import/Export limitations for the following year.

Through the participation and outcomes of the different planning processes the Company participates in, several vital pieces of the long-term planning picture are analyzed and updated on an annual basis. This enables development of the most cost effective and efficient solutions and direction in the long-term use of the transmission system at a local, regional and interconnection-wide level.

4. Black Start

At a high level, a Black Start Plan specifies the process we use to restore our grid to full operation without relying on the external transmission network, following a full- or partial-black out. Black Start Plans are required by NERC, developed in concert with neighboring utilities, and are subject to review and approval by MISO. Developing such a plan involves developing models, strategies and procedures to configure the system such that one or more generators can be brought online – and at the same time, picking-up sufficient customer load to satisfy the generator's minimum requirements for stability. The longer the system is down, the harder it is to restore, so we work to determine the most efficient paths possible.[16]

The restoration is initiated under the instruction of the Transmission Operator and

[15] *See* Docket No. E002, ET6675/CN-17-184 or www.huntleywilmarth.com)
[16] The longer the system is down, equipment and facilities cool. Additional impacts include effects such as the fact that substation batteries will only keep the substations operational for a limited time. If the substation batteries deplete, we cannot easily isolate or energize the substation.

proceeds under the general guidance of a site specific restoration plan. Not all power generation units have, or are required to have, this Black Start capability. Black Start-capable generating units have specific configurations, additional on-site emergency generators and must be held to the highest reliability standards to ensure responsiveness in the face of an emergency.

III. THE GRID IS EVOLVING

A. The Introduction of Energy Markets

The electrical transmission system has moved from being a locally-owned and operated power system that was weakly tied to one another through high-voltage transmission lines to a regional model focused on efficiency and reliability.

Through the incorporation and membership in the regional RTOs, locally-owned transmission facilities have been turned over to the function control of regional grid operators to participate in open and effective wholesale energy markets. Through the creation and operations of the wholesale electrical markets, MISO has effectively delivered a more efficient system. Where the old power pool had reserve requirements up to and exceeding 25 percent of the utility's demand, MISO – using modern modeling and markets operations – has been able to significantly reduce spinning reserve requirements (the most costly reserve requirement) for the region. In addition to the more efficient use of existing resources, this construct has allowed for more of the older, less efficient power plants to retire while maintaining system reliability.

MISO's open access Generator Interconnection Queue allows for new generation that has requested interconnection service to be studied for inclusion into the transmission system. This process ensures that there is a fair and transparent process for all generators to have unbiased access to the regions transmission system and allows competitive participation in the wholesale energy market. MISO's Wholesale Energy Market allows for the region to have the lowest cost generation mix available at the time while maintaining system reliability through a process referred to as a Security Constrained Economic Dispatch (SCED). One key aspect of market participation enables each generator owner to bid into the market at competitive prices ensuring the lowest wholesale energy cost for the customers across the MISO footprint. We discuss the current status and challenges with the MISO interconnection queue that are creating uncertainty for planning purposes in Appendix I: Supporting Infrastructure: Transmission & Distribution.

B. Shifting Resource Types and Mix

One major benefit realized through the implementation of an open and competitive wholesale energy market is the ability for zero-emission and renewable sources of generation being allowed to compete on a fair and equitable basis with more traditional forms of generation. Due to this, renewable development has grown in the MISO region largely through expansion of wind resources to-date – with significant growth in solar expected. The current significant wind resources are primarily in southwest Minnesota and northern Iowa, but over time have also expanded to almost every part of the MISO system.

1. Rapid Increase in Renewables

In the year 2000, there were approximately 2,500 MW of wind on the transmission system across the entire United States. Today, there is over 18,000 MW of wind just in the MISO footprint – with solar power now also being added to the mix. The initial drive for renewables was created through the development of public policy initiatives that allowed for tax credits to make the renewables more cost competitive against the more traditional coal and nuclear prices and set renewable energy goals for utilities subject to those local regulations. More recently, renewable forms of generation resources have been selected purely as the most economic resources. In addition to the more competitive renewable costs, public opinion has driven the push for a more carbon-neutral set of generating resources.

Since the first wind turbines were installed, the price for wind has dropped dramatically. As manufacturing processes have improved, and supply chain efficiencies incorporated, some economies of scale were realized, driving lower costs for new wind turbines. In addition to solely reducing installation costs, improvements in the power electronics have improved the performance of the new wind turbines to help with system reliability. Solar from both small and large utility-scale resources are increasingly part of the resource mix. Public policies for new solar coupled with dropping prices and tax incentives are helping to drive the increase. Solar has the added benefit of its peak output being closely correlated with peak demand.

Energy storage is just starting to be used in utility-scale settings, with processes only just now being developed to incorporate these technologies into long-term planning efforts. There are several energy storage methods that are being studied for commercial applications, one of which is battery storage. Battery storage is already being tested and incorporated in some electric markets around the world. Battery storage offers the ability to store excess power created that cannot reach customers at the time of generation, and release that stored energy when the system demands it.

Batteries have several benefits, including the ability to store power for the purposes of helping with grid stability through power electronics and small scale power injections and withdrawals as well as shifting energy production to hours with high demand. While batteries will play a roll in our carbon reduction goals, current technologies in the early stages of commercial use, and because of this, have not yet incorporated manufacturing and supply chain efficiencies that have made wind and solar generation resources more cost competitive.

2. The Changing Generation Mix is Putting Pressure on Area Reserve Requirements

In the wake of the electrical system transforming from local power pools to regional markets that include increasing levels of non-traditional and renewable resources, there has been an increase in the rate of retirements of aging baseload generating units. Most of the generation replacing these traditional, dispatchable units are from intermittent resources such as wind and solar. Because these intermittent resources are dependent on fuel availability (wind blowing or sun shining), their replacement of retired dispatchable units is putting extra pressure on the reserve requirements for the region, since wind and solar cannot be counted on at all times. While MISO recognizes this and is studying issues related to high renewable penetrations in its RIIA study, its planning construct has not yet adapted to recognize this reality. We discuss the RIIA study below, and in Appendix J2, along with our development of a Reliability Requirement as a bridge until the MISO planning construct changes.

In addition, most of the best locations to develop cost-effective wind and solar resources are located away, and in some cases, far away from populated areas and thus load centers. This requires a robust network of large bulk electric transmission lines to bring the renewable power to the load, which means that significant transmission development will be needed to support increasing levels of renewables. However, the more transmission infrastructure between the renewable resources and the load centers, the greater the risk that those resources will be unavailable to the load centers when needed. This is because long transmission line(s) are more likely than a short line to be impacted by severe weather or some other event that along the line – making it unavailable to deliver the energy from the resource(s). This reality lowers the accreditation of the renewable resource(s) – and increases the reserve requirements for the area.

3. Growing Penetrations of Distributed Energy Resources

In addition to baseload retirements and the rapid expansion of renewable generation resources, growing reliance on DER, including DR, introduce strains to the transmission system that have not been historically encountered. While both of these

resources represent important and useful tools in planning for a reliable and cost-effective power system, they have indirect and sometimes counter-intuitive impacts on the transmission system. In levels that do not produce what would be considered reverse flows, resources originating on the distribution system and flowing onto the transmission system look similar to a localized reduction in demand on the transmission system. From a high level, this should only result in a reduction in the generation required to meet the demand. However, because of low market offer prices for renewable resources in the MISO market, when this localized reduction in demand occurs, it serves to increase long distance transfers on the transmission system, causing strain on those facilities.

4. *Planning Impacts of the Shifting Resource Mix*

A part of the MISO planning processes is an annual analysis of reserve levels. Planning reserves are the margin by which resources exceed expected customer demand. MISO's Resource Adequacy process establishes the margin by which each utility's resources are required to exceed demand in order to cover potential uncertainty in the availability of resources or level of demand.[17]

Reserve analysis is also incorporated into the NERC Long-Term Reliability Assessment (LTRA), which is an annual report highlighting national and regional trends and potential risks over a 10-year assessment period. While it is fairly common for a planning region to drop below the reference reserve margin levels in later years of the assessment period, the 2018 LTRA report specifically calls out MISO as one of three regions that are projected to drop below their reference reserve margin levels earlier than normally encountered – specifically by the year 2023.[18]

This report indicates that inclusion of generation with high likelihood of being incorporated into the MISO system (known as Tier 2 resources in the LTRA) would likely allow for the MISO footprint to preserve system reliability.[19] That being said, there has been an unprecedented rate of baseload generation retirements announced, but that are not yet taken into account in this analysis. There is also uncertainty regarding future capacity accreditation levels for renewable resources, particularly, as

[17] Factors affecting availability and demand include: Planned maintenance, Unplanned or forced outages of generating facilities, Deratings in resource capabilities, Variations in weather, and Load forecasting uncertainty.

[18] https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2018_12202018.pdf

[19] NERC defines Tier 2 resources as being in the interconnection queue and having a signed/approved completion of a feasibility study, signed/approved completion of a system impact study, signed/approved completion of a facilities study, requested Interconnection Service Agreement, or is included in an integrated resource plan or under a regulatory environment that mandates a resource adequacy requirement (Applies to RTOs/ISOs).

well as the potential for increased reserve requirements. This all combines to cast doubt on whether those Tier 2 resources relied upon in the LTRA alone are sufficient to provide adequate reserves to mitigate the identified risk. Further, when considering the findings from NERC's *Generator Retirement Scenario Special Study*, we believe there is an increased level of risk that baseload generation retirement requests may result in system support resource (SSR) (or something similar) designations[20] – as was the case with our Sherco Units 1 and 2 MISO Attachment Y2 study, discussed in our last Resource Plan.

C. Early Studies Did Not Fully Contemplate the Level of Change Underway

When the wind generation was first injecting energy into the system, it was in small amounts that were able to utilize the existing bulk and non-bulk AC power system. The existing AC power system was developed to deliver energy to customers from large centralized power stations usually located next to areas of the highest customer demand. As more and more renewables were added to the system the AC grid has had to morph into more a hybrid system that shifts power back and forth depending on the generation pattern for the day.

Early studies done on the system did not anticipate the impact that rapid adoption of renewables would have on the existing system. These studies also tended to underestimate the early retirement of existing resources that provide important support to the system. We discuss these early studies below.

1. Upper Midwest Transmission Development Initiative

The Upper Midwest Transmission Development Initiative (UMTDI) was developed in 2008 as a coordination effort between the States of Iowa, Minnesota, North Dakota, South Dakota and Wisconsin tasked with accomplishing two major tasks: (1) Establish a plan that will guide and encourage the construction of interstate transmission lines to serve the upper Midwest region's commitment to cost-effective renewable generation while maintaining reliability, and (2) Develop an equitable cost-sharing methodology for new transmission facilities.

A final report from the initiative provided five high-level areas that represented barriers to development of transmission to enable renewable generation:

- *The need for certainty in regional planning for transmission.* Developers and regulators

[20] In MISO, in some cases, a generator may be designated as a System Support Resource (SSR), which is determined by the presence of unresolved violations of reliability criteria that can only be alleviated by the SSR generator and where no other mitigation is available.

need to know what the rules are for transmission planning. In the absence of such certainty, development stalls and the potential for inaccurate decision-making arises.

- *The right balance between remote and local renewable generation.* There is a need to cost effectively balance highly efficient renewable energy resources far from customers with local renewable energy resources closer to population centers.
- *Large transmission projects are expensive and will impact electric rates.* Billions of dollars of transmission investment may be necessary. Minimizing these costs through sound planning is critical to ensure that projects get built cost effectively.
- *Large transmission projects can cause large land-use impacts.* Transmission projects require the acquisition of sizeable tracts of land for right-of-way easements. Such acquisitions garner strong reactions from landowners and neighbors and the public at large. While recognizing that each state has the ultimate siting authority for transmission lines
- *Cost allocation for the needed transmission is contentious.* Arguably the largest hurdle to new construction is how the costs get distributed. In the absence of an equitable formula, projects will not get built, or parties not benefiting from the projects will end up paying for them.

Due to the significant overlap between the UMTDI effort and Regional Generation Outlet Study (RGOS) and Regional Expansion Criteria and Benefit Task Force being performed by MISO at the same time, the group transitioned its efforts to focus on advocacy in those regional efforts.

2. MISO Regional Generation Outlet Study

Beginning in 2008, MISO initiated the RGOS in response to the passing of Renewable Portfolio Standards by several of the MISO member states mandating the expansion of renewable energy resources in state utility portfolios. The purpose of this study was to determine a best fit solution in the form of a transmission overlay encompassing all MISO states – premised on a distributed set of wind zones – each with varying capacity factors and distances from load.

Despite this early and comprehensive study work, the unprecedented growth of renewable generation and the earlier than expected retirement of baseload generation have resulted in impacts to the current system that have far exceeded what was projected in the RGOS analyses.

3. Regional Expansion Criteria and Benefits

Concurrently with the development of the RGOS overlays, the MISO stakeholders developed the first significant round of cost allocation principles for transmission projects. This provided a formal process for assigning cost responsibility for transmission upgrades to in a way that is roughly commensurate with beneficiaries.

4. Minnesota Renewable Energy Integration and Transmission Study

In 2013, the Minnesota Renewable Energy Integration and Transmission Study (MRITS) was initiated to build upon prior work with respect to the integration of renewable energy, specifically looking at a potential increase of the Minnesota Renewable Energy Standard (RES) to 40 percent by 2030, and higher levels beyond that timeframe. The purpose of this study was to determine the reliability impacts of increase variable generation development as well as determining associated cost impacts.

The study consisted of three core analyses:

- *Power flow analysis* was utilized to develop a conceptual transmission plan, including transmission expansion required for both interconnection of additional variable resources as well as required expansion to allow the energy from those resources to reach the wider region.
- *Dynamics analysis* was utilized to determine issues with system stability and system strength.
- *Production Cost analysis* to determine more operationally focused challenges to the integration of significant levels of variable resources.

The results of this study stated that 40 percent of Minnesota's retail electricity sales can be reliably accommodate with upgrades to the existing system at the time of the analysis.

However, while there were several important pieces of information gleaned from the MRITS study, the unprecedented expansion of variable generation that has occurred combined with the retirement of several large baseload generators that was not fully anticipated at the time of this study, has made the assumptions that went into this analysis outdated – and as such, the full results cannot be directly applied to today's transmission system.

D. MISO Processes Must Further Evolve

To accommodate the rapid expansion of renewable generation resources in the region, MISO's generation interconnection process has undergone several process improvements, but does not yet fully reflect the state of the evolving grid. As additional variable generation replaces firm dispatchable resources, issues such as weak signal strength and system instability become more likely. Current interconnection processes study only two conditions (summer/peak and shoulder); current resource adequacy processes assign fixed annual capacity values to variable resources based on their *average* contribution to the grid. These practices do not properly assess other grid conditions for potential reliability impacts – nor do they recognize the portion of time that variable resources will provide less or no energy and capacity to serve customers.

When a large batch of inverter-based generation performs outside of what is expected, models typically show that the system can survive adverse conditions. But in 2016, the Australia power system experienced storm damage that forced several transmission lines to open. The wind farms that were being relied upon on at that time were not able to survive multiple ride-through capability cycles, and started to trip offline – resulting in a large-scale power outage in southern Australia. While there are standards and practices in place in the Eastern Interconnection, MISO and Minnesota transmission systems to help avoid this same scenario, the rapid escalation of renewable resources and the earlier than expected retirement of baseload generation places a greater strain on the transmission system to deliver more remote sources of generation, and increases the likelihood of events similar to the Australia power outage occurring on the local transmission system.

MISO's early generation queue was done in order of requests. While this process allowed for concrete identification of issues caused by individual generator interconnection requests, it was a slow and tedious process of study after study, followed by restudies when the inevitable request withdrawal happened.

As the rapid development of renewables continued, MISO shifted to group studies process to help deal with the volume of requests. This greatly increased the ability of the MISO process to analyze larger sets of interconnection requests, but failed to address the issues of restudies, queue parking and withdrawals. The most recent iteration of generator interconnection process changes incorporated elements to remove the ability to suspend requests, set higher hurdles for continuation through the process and incent early withdrawals of projects that are unable to complete the interconnection process at that time. While these studies are sufficient to determine network upgrades to allow interconnection of the requested facilities, they are

performed with models of the existing system *at the time* of the study, which does not include future generation retirements, unless they are formally-confirmed.

Current generator interconnection studies are based on two conditions, summer and shoulder, and determine the system improvements needed for each study group. This is to represent two of the most strenuous scenarios for the transmission system – one during peak customer demand, in which all resources are employed to meet that demand – and the other, a scenario representing lower customer demand and high renewable generation output, leading to high levels of power transfers across the transmission system. Even though these two strenuous scenarios are analyzed, there are system conditions that exist that put a large strain on the system and are not studied as part of the generation interconnection process.

For example, MISO experienced a low wind day July 29, 2018, where wind produced below the accredited levels for more than 100 consecutive hours. Another example is during the most recent polar vortex when the vast majority of wind turbines shut down due to extreme cold temperatures, and output dropped sooner than the forecast had predicted. As a result, firm dispatchable resources were needed to fill the gap left by the forecast error and lack of wind. We discuss these case study days further in conjunction with the Reliability Requirement in Appendix J2.

As the grid further evolves to include increasing levels of renewable resources, there will be an increased need to identify impacts and propose solutions that ensure reliable delivery of energy every hour of every day, rather than relying on limited snapshots. These events that limit the availability of resources below what is expected are extreme and may represent only a small portion of potential operating conditions, but maintaining a reliable system through *all conditions* will be important in the changing future.

IV. XCEL ENERGY BASELOAD GENERATING RESOURCES STUDY

Order Point No. 14(a) of the Commission's January 11, 2017 Order in Docket No. E002/RP-15-21 required Company in its next Resource Plan to study the future of its baseload generating resources, and describe its plans and possible scenarios for cost-effective and orderly retirement of its aging baseload fleet, including Sherco, King, Monticello, and Prairie Island. In this section, we outline the four-pronged approach we took to conduct this analysis.

A. Overview

Aging baseload generator retirements and increasing levels of renewable generation

on the grid are trends underway in the industry that are not yet fully understood. The current transmission system is developed, operated and maintained in accordance with several sets of standards and processes to ensure the safe, reliable and efficient delivery of power. Some of these include standards and recommendations from the Institute of Electrical and Electronics Engineers (IEEE), the National Electric Safety Code (NESC), the Nation Electric Code (NEC) and countless industry standards referred to as "Good Utility Practice." One of the most impactful to the development, planning and operation of the transmission system is the standards set by NERC, which through the authority of FERC, has the ability to enforce the established NERC standards under penalty of fines. NERC standards touch on everything from system modeling requirements to system operations, including both physical and cyber security standards. Embedded in these standards are local system practices and protocols from which the standards are formulated.

While these standards and protocols have worked well in the past, the changes underway on the grid are introducing new challenges. This requires additional foresight in planning processes to ensure reliable delivery of power to customers utilizing a cost-effective transmission system. Although the trend toward high penetration levels of intermittent generation has been commonplace for several years, the industry is just starting to analyze the impacts of these changes from a holistic point of view. MISO and individual utility planning and study practices will need to adapt to ensure we continue to have a resilient system and strong customer reliability.

That said, the work that we have done with this Baseload Study provides helpful insights into this complex intersection of the future grid. Further studies and an orderly plan will be key to ensuring reliability and resilience through the clean energy transition we envision for our system.

B. Approach

The NSP System has been developed over the past 100 years to serve the growing area, and is constantly being analyzed to ensure optimal and reliable power delivery. We have a great deal of experience both in studying the existing grid and operating it in many varying conditions (during high load, low load, high transfers, low transfers, storm conditions, outages or equipment). However, as noted above, planning and study practices have not fully adapted to trends underway. We believe however, that our technical and economic approach combined with relevant industry insights in this Study provides helpful insights to an orderly and cost-effective retirement of our current baseload generating units.

The components of our Study are as follows:

- **Midcontinent Integrated Systems Operator (MISO) Attachment Y2 preliminary retirement studies**, which assessed various single Unit and combined Unit retirement scenarios for thermal and voltage concerns,
- **Xcel Energy Transmission Reliability studies**, which examined system stability and response impacts associated with baseload generating resource changes on the NSP System and on neighboring systems,
- **Industry insights**, including the North American Electric Reliability Corporation (NERC) *Generator Retirement Scenario Special Study* and the MISO *Renewable Integration Impact Analysis* (RIIA), which provide important insights into the combined effects of baseload generator retirements in a region and grid impacts at increasing levels of renewables penetration, and
- **A focused Strategist analysis**, which examined the economic implications of various Unit and combined Unit retirements at different points in time.

When performing technical studies, we simulate a number of varied conditions that can consider changes in customer loads, projected changes to the generation mix, and ways to use the transmission system most efficiently. The studies generally analyze the way power flows over the grid and search for places where the system might overload or fail, assuming specific circumstances. While these studies are essential and provide important insights, our decades of operating and studying the existing system also provides valuable insights and perspective toward assessing potential impacts from NSP System grid changes. We have incorporated this experience into our analysis of impacts. We also supplemented our technical study efforts with relevant industry initiatives that examine the compound impacts of aging baseload retirements and increasing levels of renewable generation – similar to the issues facing the NSP System.

The MISO Y2 and our Reliability Studies identify grid impacts and potential transmission mitigations necessary to resolve the respective issues the studies identified. MISO performed its Y2 Studies in accordance with their Business Practice Manuals, which generally focus on thermal and voltage issues.[21] We used the MISO planning level estimated mitigation costs from the Y2 studies as an input to our Strategist modeling of the baseload unit retirements. While these may not be the final mitigations, they provide a proxy of potential costs to inform the economic aspect of our Baseload Study. Our technical studies supplemented the MISO analysis to examine traditional NERC reliability measures such as system stability and response.

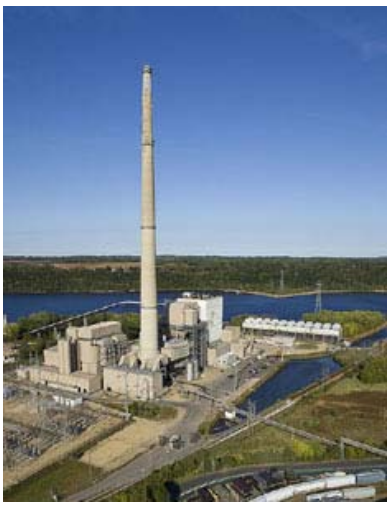
[21] *See* MISO Business Practice Manual BPM-020 at:
https://www.misoenergy.org/Library/BusinessPracticesManuals/Pages/BusinessPracticesManuals.aspx

This is an important complement to the MISO Y2 studies to provide a more robust look at potential impacts from baseload changes on the NSP system and regional MISO grid.

All studies are essentially an attempt to predict what is going to happen in the future – and the conditions and underlying assumptions of a dynamic system are subject to change. These technical studies used the best information available at the time they were initiated. However, while the studies provide important insights, there are inherent limitations in any study effort. Technical studies simulating the removal/ absence of a generating unit(s) on the grid can only practicably analyze potential impacts with a point-in-time model in a limited set of grid conditions (i.e., peak, shoulder, etc.). Therefore, while they provide important insights for the limited number of scenarios studied, it is important to supplement the technical studies with industry insights and engineering judgement. We have attempted to offset these limitations by taking a multi-faceted approach to our Study, and note that further studies more proximate in time to the potential retirement dates will be necessary to determine actual impacts and actual mitigations.

C. Xcel Energy Baseload Resources Fleet

1. A. S. King



This plant was named in honor of Allen S. King, former president and chairman of Northern States Power Company, a predecessor to Xcel Energy. The King plant underwent a significant rehabilitation from 2004-2007 as part of Xcel Energy's Metro Emissions Reduction Project (MERP).

<u>Key Facts</u>

- *Power Production Capability:* 598 megawatts
- *Commercial Operation:* 1968
- *Generation Type:* Coal
- *Location:* Oak Park Heights, Minnesota, on the St. Croix River

In addition to generating electricity, A. S. King supplies hot water to neighboring Andersen Windows, a large window manufacturer. Located on the border of Minnesota and Wisconsin, King also provides stability to the Upper Midwest transmission grid.

2. Sherburne County (Sherco) Generating Station

The Sherco plant is comprised of three generating Units with a total nameplate capacity of approximately 2,400 MW. Sherco is the largest plant in the Company's fleet in terms of square feet, steam production, and power generation capability. Units 1 and 2 are scheduled to retire in 2026 and 2023, respectively. This Resource Plan proposes to retire Unit 3 in 2030. Unit 3 is 41 percent owned by Southern Minnesota Municipal Power Agency, composed of municipal power companies operating on a cooperative basis.

Key facts

- Power Production Capability: 2,457 MW
  - Unit 1 – 765 MW
  - Unit 2 – 765 MW
  - Unit 3 – 927 MW
- *Commercial Operation:* Unit 1 - 1976; Unit 2- 1977; Unit 3 - 1987
- Generation Type: Steam Turbine
- *Location:* Becker, Minnesota, 45 miles northwest of the Twin Cities, on the Mississippi River

3. Monticello Nuclear Generating Station

The Monticello facility is among Xcel Energy's lowest-cost sources of electric generation on a per-megawatt basis and produces virtually no greenhouse gas emissions. As a base load 'always-on' plant, it runs essentially 24 hours a day, 7 days a week, except during refueling outages, which occur about every two years. Monti is a boiling water reactor plant is located on a 215-acre site 40 miles northwest of the Twin Cities. The plant generates approximately 10 percent of the electricity used by Xcel Energy's customers in the Upper Midwest.

Key Facts

- *Power Production Capability:* 671 Megawatts
- *Fuel Type:* Nuclear
- *Location:* Monticello, Minnesota

The plant received a 40-year operating license from the federal Nuclear Regulatory Commission in 1970, and it began commercial operation in 1971. In 2006, the NRC renewed the Monticello plant's license for 20 years, which allows operations until 2030. This Resource Plan proposes to extend the operation of the Monticello plant an additional 10 years, which will require a license extension from the NRC.

4. Prairie Island Nuclear Generating Station

The two pressurized water reactors at the Prairie Island facility generate about 20 percent of the electricity used by Xcel Energy's customers in the Upper Midwest. Prairie Island is among our lowest-cost sources of generation on a per megawatt-hour basis, and does not produce any greenhouse gas emissions. The plant runs essentially 24 hours a day, seven days per week, except during refueling outages, which occur approximately every 18 months and last about four to six weeks. The plant is about 40 miles southeast of Minneapolis-St. Paul and generates enough electricity to power about 1 million homes.

Key Facts

- *Power Production Capability:* 1,186 megawatts (593 MW per Unit)
- *Fuel Type:* Nuclear
- *Location:* Red Wing, Minnesota

The Unit 1 reactor began operating in December 1973 and the Unit 2 reactor in December 1974. The Nuclear Regulatory Commission first licensed the reactors for 40 years of operation and extended those licenses for an additional 20 years, until 2033 and 2034.

The Prairie Island and Monticello nuclear generating plants help Xcel Energy avoid producing hundreds of millions of tons of greenhouse gases or emissions. The plants avoid 13 million tons of carbon dioxide annually compared to fossil fuel plants, the equivalent of removing 2 million cars from the road each year.

D. Industry Studies and Outlook

We also considered industry trends and relevant studies on the effects of aging baseload units and the cumulative effects of higher renewables penetrations. Two of these studies were the MISO *Renewable Integration Impact Assessment* (RIIA) study, which is ongoing, and the December 2018 NERC *Generator Retirement Scenario Special Reliability Assessment.*

1. Industry Study – MISO Renewable Integration Impact Assessment

In 2017, MISO initiated a detailed exploration of assumptions regarding the way the electrical grid will work in the future in light the "profound" change in the types of generating resources across its operating area and the implications that such a shift means for long-standing power system design and operational practices. Under current practices, renewable resources are relied on mostly for their energy production attributes, but as they continue to replace existing assets, they will be expected to increase their contribution to grid reliability.

Given the current structure (physical infrastructure, operational practices, regulations, etc.) of the electric system in MISO and beyond, there are limitations on the maximum penetration of renewable energy. The complexity of overcoming these limitations are dependent on the types and distribution of renewable resources, the current layout of existing assets, and the actions of neighboring regions. Because the exact points of these limitations are not yet known, a framework is needed to examine renewable integration over a wide range of penetration levels, starting with the system we have today and examining penetration levels up to very high percentages of annual energy. This framework, when completed, will reflect and inform the conversations that MISO and other entities within the electricity sector have been having on the impacts of the evolving resource mix on the BES.

The study has three focus areas: (1) Resource Adequacy, or the ability to maintain the Planning Reserve Margin; (2) Energy Adequacy, or the ability to operate within generator limits such as ramp rates, min/max capacity, etc., transmission limits/ratings, and system limits such as energy balance and operating reserves; and (3) Operating Reliability, or the ability to operate the system within acceptable voltage and thermal limits and the ability to maintain stable frequency and voltage, and meet system performance requirements. The study is being conducted in phases, with each phase examining increased levels renewable penetration. Phase II was completed in Q1 2019, and examined region-wide renewable penetrations in the 40-50 percent range.

This is being accomplished by identifying "milestones" or inflection points of integration complexity, initially identified through four modules:

- *Operational Adequacy*. Simulation of the Day-Ahead (DA) and Real-Time (RT) to examine the Ancillary Services Market (ASM), including aspects such as ramping, emergency/dump energy, reserve requirements, congestion, etc..
- *Transmission Adequacy*. Analysis of the power system utilizing more traditional power system analyses. This analysis examines peak demand, shoulder demand and low demand scenarios to assess the ability of the transmission system at each milestone.
- *System Stability*. Analysis of the very short term capabilities of the transmission system to maintain system stability. This analysis utilizes scenarios similar to the Transmission Adequacy module, but focuses on the sub-second to multiple second response timeframe to determine the ability to maintain voltage and transient stability and ensure adequate system response capability is available.
- *Resource Adequacy Limitations*. Determination of the impacts to resource reserve margins and load carrying capability of intermittent resources and interdependencies between resource types.

These modules are being applied through three Phases that study these impacts at increasing levels of renewable resources.

a. Key Takeaways To-Date

One of MISO's key conclusions to-date is that integration complexity increases dramatically between 30 percent and 40 percent. At a 40 percent MISO-wide renewables penetration level, curtailments are encountered during almost all non-summer days, reaching nearly 7,000 GWh of curtailments in the worst month of the base case at this level. Other interim conclusions relevant to our study of an orderly cost-effective transition of our baseload units thus far include:

- Renewable integration complexity increases sharply from 30 percent to 40 percent penetration. Currently synchronous baseload units provide necessary services to the grid that mitigate the impacts of the inherent variability of renewable generation.
- As wind and solar penetration increases, its contribution to peak load conditions reduces because the risk of losing load compresses into a smaller number of hours and shifts to later in the day (from 3:00 p.m. to 6:00 p.m). As a result, the available energy from wind and solar during high risk hours

decreases, and the marginal contribution of renewables reaches a plateau. We discuss this further in Part IV.D below, and in conjunction with the Reliability Requirement we developed for this Resource Plan, discussed in Appendix J2. This issue is both a current and future risk to system resilience and reliability that is not currently addressed in the MISO planning construct.

- As renewable penetration grows, renewable curtailment becomes increasingly significant; enhanced transmission reduces curtailment. With increased levels of renewables inevitable to achieve significant carbon reductions, substantial transmission development will be necessary.
- As renewable penetration increases, the number of thermal units online increases during off-peak hours despite a decrease in average output – and fewer thermal units are operating at their minimum stable level.
- Thermal overloads and voltage violations increase as penetration levels increase, with solution complexity (cost of the transmission fixes) also increasing with penetration level. North Dakota and parts of Minnesota start to show severe thermal and short circuit issues due to vast amount of wind resources sited in those locations and relatively limited transmission capacity.
- Diversity of technologies and geography improves the ability of renewables to meet load.
- Overall, the 40 percent scenario increased the instances of dynamic stability issues, operational stressors, and resource adequacy requirement increases.

In observing that the level of renewable resources in the MISO footprint is growing at a rate of about 1.5 GW per year since being nearly non-existent in 2005, MISO acknowledged challenges along the way – and is taking action to evaluate the impacts of renewable resources growing to even higher levels over the long-term. As described by MISO, its RIIA assessment will give MISO and its stakeholders specific areas around which to focus effort and help inform the sequencing of actions required to manage certain renewable penetration levels. The assessment will illustrate specific areas of system weakness, show when those weaknesses could become problematic and identify potential means to address them – and will seek to facilitate a broader conversation about renewable integration impacts on the reliability of the electric system.[22] The study is now continuing on to Phase III.

[22] *See* https://www.misoenergy.org/planning/policy-studies/Renewable-integration-impact-assessment/#t=10&p=0&s=&sd=

2. *Industry Study – NERC Special Reliability Assessment – Generation Retirement Scenario*

Below we summarize a recent special report from NERC that implies there may be potential for delay or cancellation of announced retirements due to insufficient system support services provided by synchronous generation being available in some regions.

NERC published a Generation Retirement Scenario Special Reliability Assessment December 18, 2018 as part of its ongoing efforts to assess the potential implications of the changing generation resource mix on the reliability of the North American BES. In initiating this special assessment NERC observed that the BES is undergoing a significant transformation, marked by growth in new natural gas, wind, and solar resources replacing retiring fossil-fired and nuclear generating resources. The drivers underlying this shift that NERC cited include federal and state policies, continued low natural gas prices, wholesale market forces, customer preference, and low and improving technology costs.

NERC also observed that managing generator retirements and the transition to replacement resources is a complex process. The report characterizes the changes currently underway with the generation resource mix as "revolutionary," and observes that the changes alter the operating characteristics and constraints of the BES. The report stresses that these changing characteristics must be well understood and incorporated into planning to assure continued reliability.[23]

NERC's key conclusion is that the generator retirements that are occurring disproportionately affect large baseload, solid-fuel generation (coal and nuclear). If these retirements happen faster than the system can respond with replacement generation, including any necessary transmission facilities or replacement fuel infrastructure, significant reliability problems could occur. Resource planners at all levels should use their full suite of tools to manage the pace of retirements and ensure replacement infrastructure can be developed and placed in service. Ensuring reliability throughout a significant retirement transition will likely include construction of new transmission and fuel infrastructure

This NERC study underscores the importance of taking a measured approach to baseload unit retirement that includes thorough examination of potential reliability implications. This also supports our belief that appropriate analysis may require supplemental study beyond the studies prescribed in present protocols.

[23] Executive Summary, NERC Special Reliability Assessment: Generation Retirement Scenario (December 18, 2018).

As part of its oversight and governance activities, NERC also conducts an annual reserve margin analysis across all system operators in North America in a report called the LTRA, discussed earlier in this Study. The 2018 LTRA indicated that MISO is one of three regions that are projected to drop below their reference reserve margin levels by the year 2023, unless certain measures are taken.[24] This report indicates that inclusion of Tier 2 resources (those that are in more advanced stages of planning but not yet under construction) would likely allow for the MISO footprint to preserve system reliability. However, the unprecedented rate of announced, but not yet evaluated, baseload generation retirements and uncertainty in future firm capacity additions creates a tension between maintaining reliability and transitioning away from baseload generation.

E. MISO Retirement Studies

The current process for retirement of generation resources in the MISO footprint is generally governed by Attachment Y to the MISO Tariff. Preliminary retirement studies fall under Attachment Y2, which is a confidential MISO analysis to determine if any adverse system impacts would occur as a result of potential generating resource retirement – without/prior to committing to retire or suspend the resource. If adverse impacts are identified, they provide an indication of the mitigations that would need to occur prior to actual unit retirement. As we discuss below, we submitted requests for several Attachment Y2 studies as part of this Baseload Study.

Final determination of adverse impacts however, occurs with an Attachment Y notice – or new provisions under Attachment X of the MISO Tariff, if the notice of retirement includes replacement generation. In May 2019, FERC approved changes to the Attachment X Tariff that allows current generation owners to retain and reuse the interconnection rights when a resource retires, within certain technical and timing limitations on the new generator.[25] The new generating units could be developed on the same site, or on a site in close proximity that uses the same grid interconnection point. The resulting studies under this provision of Attachment X, the generation replacement is considered as part of MISO's analysis of potential adverse impacts. We discuss Attachment X and its importance in achieving the fleet transformation we

[24] *See* "NERC Long Term Reliability Assessment 2018" at 14. Available at: https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2018_12202018.pdf

[25] In summary, these changes allow for transfer of interconnection rights from a retiring generation resource to a replacement resource that: (1) Is located at the same point of interconnection as the retiring resource, (2) Is less than or equal to the generating capacity of the retiring resource, (3) Does not result in an adverse impact to the transmission system. *See*: https://www.ferc.gov/CalendarFiles/20190515181059-ER19-1065-000.pdf

envision in Appendix I: Supporting Infrastructure: Transmission & Distribution provide with this Resource Plan.

1. Preliminary Retirement Studies of NSP System Baseload Units

Attachment Y2 studies assess current, point-in-time system impacts in the absence of the identified generating resource(s). The study impacts are measured based on the criteria set forth in the MISO Business Practices Manuals, The studies assess transmission system performance to identify any violations of planning criteria due to the unavailability of the generation resource. The relevant MISO Transmission Owner and/or regional reliability criteria are used for monitoring such violations. The Attachment Y2 studies are not intended to determine long-term system reliability impacts, which is why we supplemented them with other reliability studies to provide further insights into impacts from potential retirement scenarios. It is important to note that the assumptions used in the MISO Y2 studies are based on expected conditions at the time they were initiated in 2018, plus the addition of certain pending and proposed generating units, including the Sherco CC and our approved and in-progress wind projects.[26]

For purposes of this Baseload Study, we submitted seven Attachment Y2 study requests with MISO – all of which use a retirement date of May 31, 2027, on models developed to depict 2030 system conditions as follows:

Y2 Baseload Unit(s) Retirement Scenarios
Sherco Unit 3
Allen S. King (King)
Prairie Island (PI)
Monticello (Monti)
All Nuclear (Monti and PI)
All Coal (Sherco 3 and King)
All Coal and All Nuclear

2. Y2 Study Results

Generally, the studies found that reconductoring (or line rebuilds) and transformer replacement would be needed to achieve adequate performance for all the scenarios analyzed. In addition, the observed voltage violations would require installation of

[26] MTEP17 (built for the 2017 MISO planning cycle) model series 2027 scenarios that were scaled to represent 2030 load levels. The model also included the following pending and proposed generating units: Crowned Ridge 1 Wind, Crowned Ridge 2 Wind, Crowned Ridge 3 Wind, Blazing Star 1 Wind, Blazing Star 2 Wind, Sherco CC.

extensive reactive devices throughout the region due to the loss of dynamic reactive support from the large amount of retiring resources.

The studies also found that if Xcel Energy were to retire all of its remaining baseload units about the same time, which would be the majority of the large power producing units in the Upper Midwest, it would put a substantial strain on the BES to import power from the rest of MISO. It would also substantially impact MISO's ability to balance out the system to allow for the needed high renewable transfers to other parts of MISO. The Y2 study that examined the combined retirement of the Monticello Unit 1, Prairie Island Units 1 & 2, King Unit 1 and Sherco Unit 3 at the same time stated the following:

> The combined retirement…causes extensive thermal overloads and numerous voltage issues that would require substantial reinforcements to fully address the issues and permit retirement. It is unlikely that the large number of upgrades needed to alleviate thermal overloading and voltage issues would be completed before the planned retirement date resulting in the need for one or more generators to be retained as System Support Resources.

MISO currently is able to use the large Xcel Energy baseload generating units to help balance out the system and provide significant amounts of system response – allowing for high renewable transfers to other parts of MISO. On low wind days, the large generating units are also needed to replace the lost energy from the renewable sources to reliably serve customers' needs. An orderly retirement schedule with sufficient lead times is necessary to ensure reliability mitigations and adequate support of renewables integration and transfers, including generator replacements and transmission development.

Incremental retirements identified more manageable impacts. In the case of a King-only or Sherco 3-only retirement, neither resulted in thermal or voltage degradation such that the Unit would be designated as a SSR.[27] However, the All Coal/King and Sherco 3 combined study found the need for an estimated $38.2 million to address several thermal overloads. The Monticello Y2 study showed some thermal overloads that could be addressed with system readjustment. Some voltage issues would additionally need to be addressed before it could retire. The retirement of Prairie Island would require some voltage mitigation, but there were no thermal overload

[27] In some cases, a generator may be designated as a System Support Resource (SSR), which is determined by the presence of unresolved violations of reliability criteria that can only be alleviated by the SSR generator and where no other mitigation is available. Evaluation of mitigation solutions will consider the use of operating procedures and practices such as equipment switching and post-contingent Load Shedding plans allowed in the operating horizon.

issues. Retirement of all nuclear units would result in some thermal and voltage issues that would need mitigation before they could be retired.

As noted above, the All-Coal and All-Nuclear Retirement scenario resulted in major thermal and voltage violations. This scenario would require significant system upgrades to eliminate all of the thermal and voltage issues; the MISO planning level estimates for all transmission facilities improvements to address the steady state thermal and voltage issues was estimated to be $299.3 million. As transmission development, permitting and construction processes generally involve rather long timeframes of 5-7 years on the low end and as much as 15-20 years in some cases, we expect that addressing all of the system violations would involve an extensive effort over a relatively long timeframe to be complete.

That said, the MISO system is dynamic and expected conditions will change when new generation comes online, existing generation retires, new transmission lines are constructed, or existing lines are reconfigured. These results are indicative of issues requiring mitigation at the time of these studies. A more comprehensive analysis will be necessary in conjunction with a notice under Attachment Y or Attachment X in closer proximity to the planned retirements to determine final adverse impacts and to develop mitigation options.

The Y2 Studies identified planning level costs, which are estimates provided only as an indication of the upgrades needed to mitigate issues caused by the retirement(s) and are based on assumptions that include new proposed generation resources without any of the associated network upgrades.[28] The Y2 reports clarify that further analysis is required in a subsequent retirement study to fully consider only those interconnected resources with executed interconnection agreements in order to more accurately determine costs of the mitigation upgrades.

For purposes of this Baseload Study, we incorporated the MISO planning level estimated costs from the Y2 studies into our economic modeling of the baseload retirement scenarios. We outline our Strategist analysis in Part G below, and discuss it in more detail in Chapter 4: Preferred Plan, Chapter 5: Economic Modeling Framework, and Appendix F2: Strategist Modeling Assumptions & Inputs.

[28] Costs specified in the Attachment Y2 studies are based on the "MISO Transmission and Substation Cost Estimation Guide for MTEP" except where costs were established for previously identified upgrades and are subject to change.

F. Xcel Energy Transmission Reliability Studies

As discussed above, the MISO Y2 study process focuses on maintaining transmission system elements within their thermal and voltage limits.[29] While this provides a thorough analysis of the impacts of the retiring generation resource in those two areas, it does not adequately capture the impacts that resource(s) has on the stability of the power system, which requires a more focused area of study around the retiring resource.

Historically, limiting the study to voltage and thermal assessments was sufficient. This was because individual generating unit changes had limited impact on overall system reliability because there were excess capabilities from the remaining generation fleet to replace/adequately perform the necessary stability services. However, as the system moves further away from large synchronous generating facilities, system stability and response becomes a significantly greater risk for generation retirement than voltage violations or thermal constraints. Therefore, a more robust study that includes consideration of other grid impacts is necessary to ensure system reliability and resilience. The complementary studies we undertook studied other grid impacts of various generation retirement scenarios using a more traditional NERC reliability assessment approach.

Combined with the Y2 results, these studies provide a more robust analysis of the potential retirement of our remaining baseload units. The results from our analysis indicate the following:

- There will be several thermal and voltage violations that will need to be addressed to remain NERC compliant.
- The location of resources plays a large part in the ability of the system to respond to faults. In the absence of large synchronous resources replacing retiring units in place, significant transmission infrastructure development will be necessary. See Figures 2 and 3 (Stability Plots) below.
- While a zero baseload future may be able meet certain aspects of a reliable power system, current technologies cannot maintain system stability, adequately recover from contingencies, nor can they ensure reliable service to customers every hour of every day without the assistance of a sufficient level of synchronous generation.

Final system impacts will depend on the scenario, the specific Unit retirement(s), and

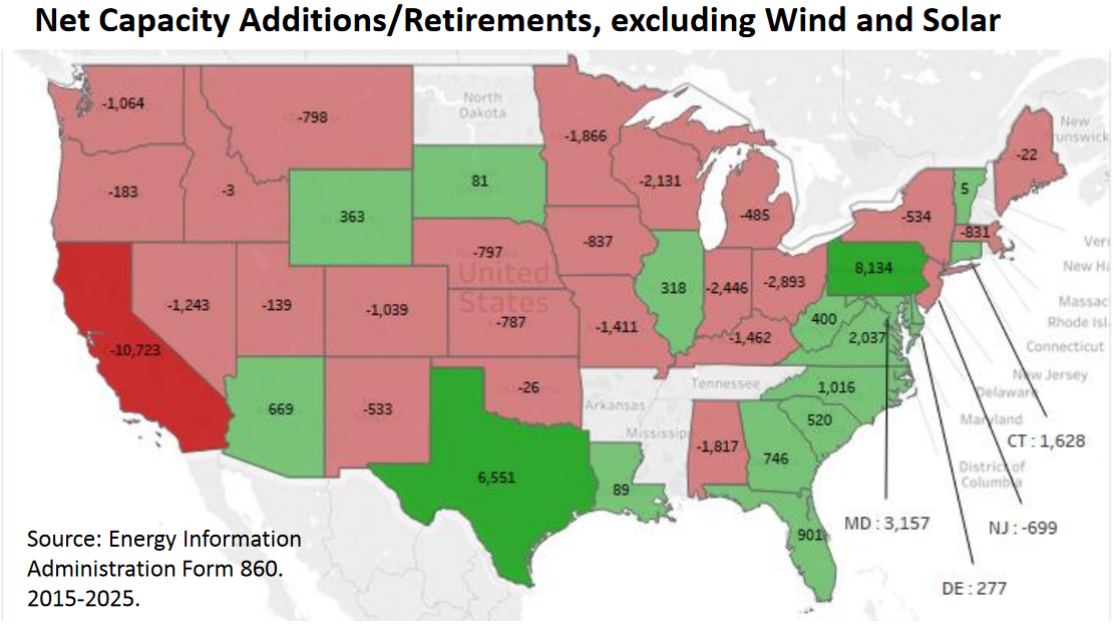
[29] MISO will perform limited stability analysis upon request.

what, if anything, will replace the Unit(s).

1. Approach

We undertook these studies at a point in time in the industry when there are more large generating units retiring than being added to the grid. As shown below, the capacity availability in the MISO states is projected to fall by nearly 8,700 MW by 2025 from 2015 totals.

Figure 1: Net Capacity Additions, Excluding Wind and Solar



With the trend of declining levels of large synchronous generating units being largely replaced with renewable and intermittent resources in mind, we undertook two study efforts to determine the impact of baseload retirements on the Upper Midwest grid:

- **Metro Stability Study** – analyzed the capability of the Twin Cities metro area to remain stable utilizing a scenario in which large scale baseload retirements took place both on the NSP System, as well as neighboring systems.
- **NSP Resource Contribution to System Stability** – analyzed the stability of the Upper Midwest grid when only the NSP System reduced its baseload generating resources.

These technical studies simulate a number of varied conditions that consider changes in customer loads, projected changes to the generation mix, and ways to use the

transmission system most efficiently. The studies generally analyze the way power flows over the grid, and search for places where the system might fail to maintain a stable power signal, assuming specific circumstances. Study 1 focused on regional (neighboring utilities') changes to determine local (Twin Cities Metro) impacts. Study 2 was to determine the regional impact of NSP System changes.

2. Study 1: Metro Stability Study

The goal of this study was to determine the minimum amount of system services required to maintain a stable major demand center, which in this case was the Twin Cities Metro area, with major changes to the surrounding system. The results indicate that while a zero baseload future may be able meet certain requirements for a reliable power system, the current technologies on the system today cannot maintain system stability without the assistance of a sufficient level of synchronous generation.

a. Study Assumptions and Approach

For the purposes of this Study, we utilized three natural gas generators located at strong points on the system to determine the *minimum amount* of system services necessary to maintain a stable major demand center with major changes to the surrounding system.[30] We performed the stability assessment using the 2018 MTEP dynamic model, representing light load with 90 percent wind output conditions in the year 2023. We assumed no load growth between 2023 and 2030 to limit the number of variables potentially affecting the results.

Consistent with the industry trends and our clean energy vision, we expect substantial additions of renewable energy to be added to the system as we transition the our generating fleet. For purposes of this Study, we assumed the addition of 5,800 MW of nameplate renewable generation dispatched at 4,440 MW to depict a higher reliance on renewable energy resources – and which would replace the assumed retirements. We show the renewable additions in Table 2 below.

[30] This does not take into account maintenance, forced outages, or economic factors into the ability of those services to be provided in all hours by the three units utilized in the analysis, which can increase the total number of units required to provide sufficient levels of service in all hours.

Table 2: Stability Study – Renewable Generation Additions Modeled

				Number of Megawatts

b. Study Methodology and Results

We then introduced faults on the system to assess the ability of the grid to recover and return to a normal state. We outline the fault events that we analyzed in Table 4.

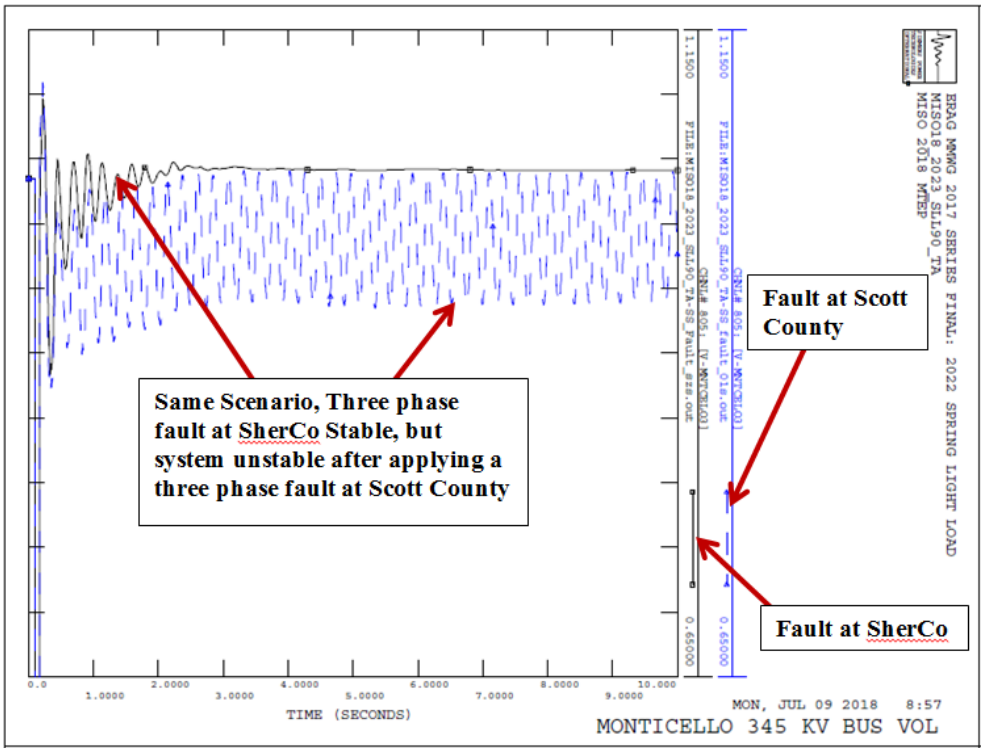
Table 4: Major Faults Analyzed

Fault Name	Fault Description	Result
Fault_01s	Normal close in 3 phase fault on Scott County - Helena 345 kV line near Scott County	Unstable
Fault_02s	Normal close in 3 phase fault on Scott County - Helena 345 kV line near Helena	Unstable
Fault_03s	Loss both Cedar Mountain – Helena circuit with normal clearing	Unstable
Fault_szs	Normal close in 3 phase fault on SherCo - Coon Creek 345 kV line near SherCo	Stable

Figure 2 illustrates the importance of location and siting on system stability. This scenario is demonstrating the effect of a single fault on the system. The black line represents a fault near our Sherco facility, which in this scenario has our future Sherco CC online; the system recovers rather quickly. The blue line represents a similar fault at Scott County, where there is no nearby generating resource – and the system

becomes unstable.

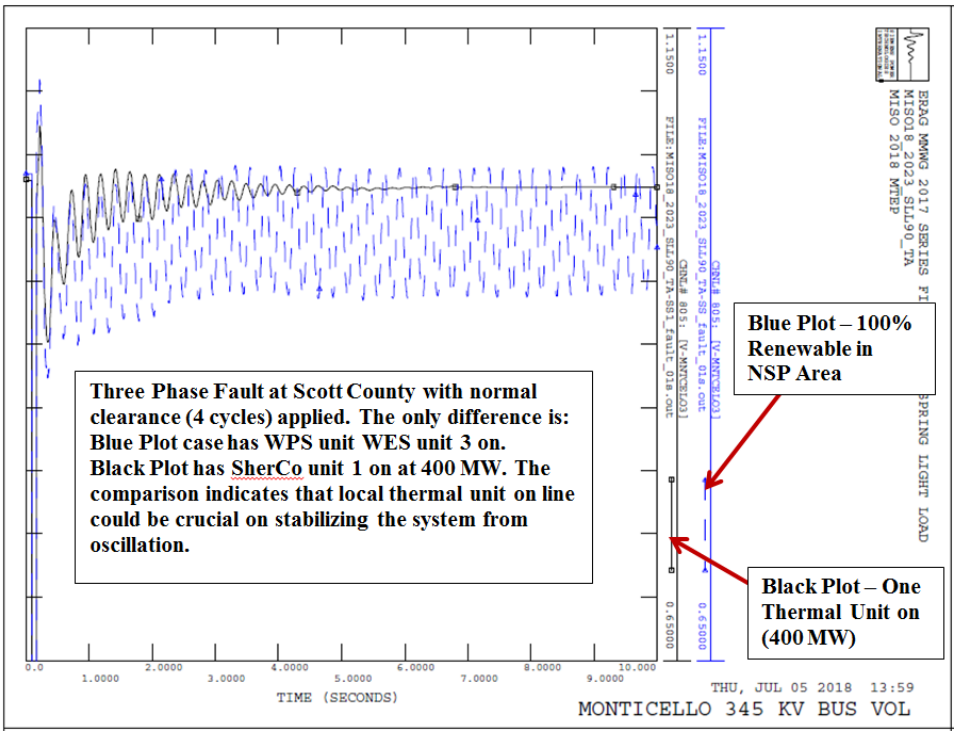
Figure 2: Stability Plot – Importance of Resource Siting on Stability



The results of this scenario demonstrate that the system remains stable when a fault occurs on a part of the transmission system where sufficient system stability services – in this case, a large synchronous generator – are available nearby. Whereas, experiencing a fault at a location with distant synchronous resources connected through long transmission lines to demand centers greatly increases the risk of system instability.

Similar to how system stability differs based on the location of the fault in relation to a system stability resource, the location of synchronous resources plays a large part in the ability of the system to respond to faults. As shown in the stability plot in Figure 3 below, the system response to a fault at Scott County is unstable when relying on energy imports from non-NSP System resources. When we moved a same-sized resource to a location nearer to the Twin Cities Metro area, the system regains stability with little issue after experiencing the same fault.

Figure 3: Stability Plot – Importance of Resource Siting on System Response



As the transition to increased reliance on renewable resources continues, replacement of synchronous resources at current resource locations or substantial transmission infrastructure development will be fundamentally essential to the reliable delivery of energy.

c. Step-by-Step Re-Aaddition of Gas Units in Metro to Regain System Stability

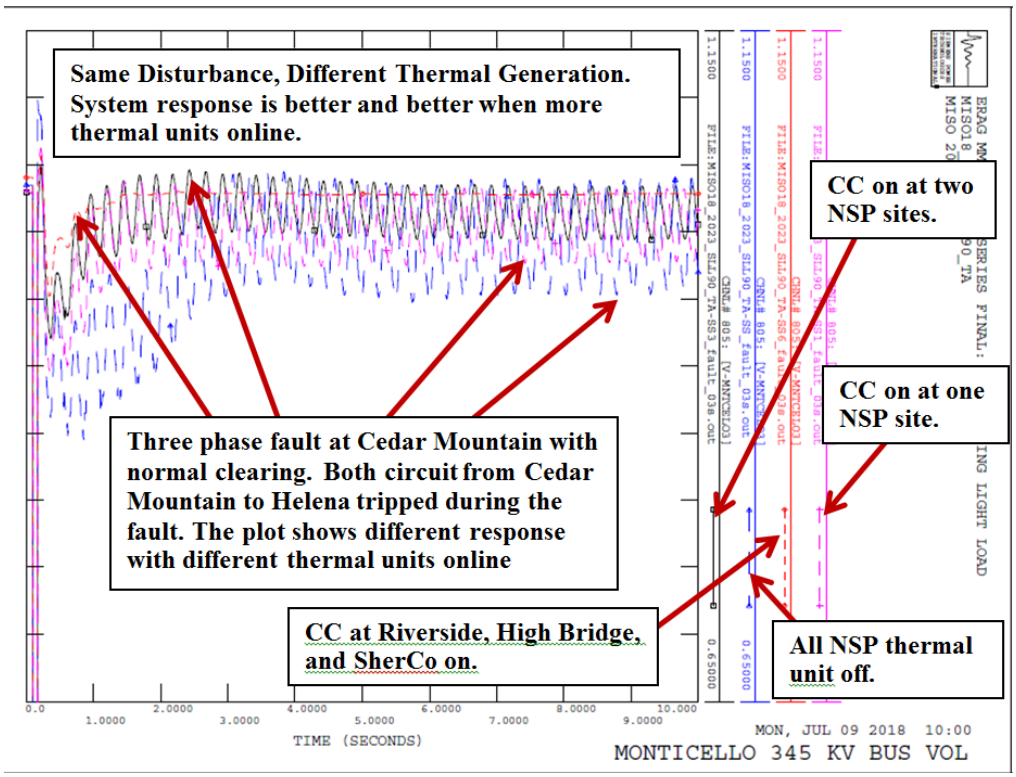
Moving away from the specific locational aspects of faults and resources, we analyzed a wider range of events of differing severities to determine what is needed to maintain system stability with high reliance on renewable resources.

To determine the level of stability services needed, we stepped through turning generating units retired in earlier scenarios back on to analyze the impacts under severe conditions. In this scenario, we turned-off all of the Upper Midwest synchronous generating units, and a major transmission path for renewable generation to get to the Metro area.

As shown in the results of this analysis below, while a zero baseload future may be able meet certain requirements for a reliable power system, the current technologies

on the grid today cannot maintain system stability without the assistance of a sufficient level of synchronous generation. An equivalent level of system services as provided in the model by Riverside, High Bridge, and the Sherco CC are all required to be operating at all times to ensure the system remains stable and can sufficiently recover from contingencies on the transmission system.

Figure 4: Incremental Steps to Result in 3-Unit Metro Equivalent Services



Every generation resource on the system can have significant impacts on the stability of the system, which may differ based on the order in which they are retired or replaced. This study demonstrates that it is vital to perform a system stability analysis, and resolve any issues, for each potential unit retirement proximate to the planned retirement, so the analysis as closely as possible mirrors expected actual conditions at the time of unit retirement.

3. Study 2: NSP Resource Contribution to System Stability

The second study also analyzed the stability of the grid in the Upper Midwest – however when only the NSP System reduced its baseload generating resources. In this analysis, we analyzed the effects of local/NSP System baseload reductions on a regional basis. Our objective with this Study was to determine the importance of

retaining sufficient system services in high demand areas (such as the Twin Cities Metro area) in order to understand the role that current NSP System baseload generating resources have on the stability of the Upper Midwest BES and the ability of non-metro locations to remain stable in low Metro-area baseload scenarios.

The results of this analysis found that the reduction in synchronous generation resources on the NSP System can have wide-ranging impacts on system stability and reliability. In particular, the retirement of NSP System baseload units without similar replacements at or near their current locations results in insufficient margin on the system during summer peak scenarios and system instability in light load scenarios.

a. Study Assumptions and Scenarios

We analyzed light load, summer shoulder, and summer peak scenarios for the year 2023 in this study. Renewables in the NSP System are modeled at an 80 percent level in all three models, while the existing natural gas CCs are turned-on to represent 20 percent firm dispatchable generation in each model. We outline the dispatch assumptions we made in the three different load scenarios in Table 5 below.

Table 5: Dispatch Assumptions

Year	Season	Load Level	20% Thermal
2023	Light Load	5,150 MW	1,030 MW
2023	Summer Shoulder	7,195 MW	1,440 MW
2023	Summer Peak	10,250 MW	2,050 MW

As with Study 1, we applied baseload unit retirements in this analysis that are not intended to represent actual retirement plans. Rather, the assumptions in Table 6 below were only used to develop a model representing the intended scenario.

Table 6: Generation Turned-Off in Analysis

Baseload Generator	Year 2023		
	Summer Light Load	Summer Shoulder	Summer Peak
Sherco #1	Offline	478.3 MW	730 MW
Sherco #2	Offline	427.2 MW	730 MW
Sherco #3	Offline	608 MW	925 MW
King	Offline	560 MW	560 MW
Monticello	593 MW	637 MW	637 MW
Prairie Island 1	553 MW	553 MW	553 MW
Prairie Island 2	552 MW	552 MW	552 MW

Table 7 below outlines the resources we used to replace energy supply in the absence of the assumed retirements above.

Table 7: Additional Generation Assumptions

Bus Number	Bus Name	Unit	2023		
			Summer Light Load	Summer Shoulder	Summer Peak
600007	RIVRS77G 16.000	7	160 MW	160 MW	Online

600172	G261 MEC CT215.000	1	N/A	N/A	Online
600046	G261 MEC-ST 19.500	1	N/A	N/A	Online

In this Study, we compare the transmission line outages to a Base scenario that has no outages, as follows:

- Base: No Outages
- Outage #1 (PO1): Sheas Lake – Helena 345 kV line
- Outage #2 (PO2): Scott County – Helena 345 kV line
- Outage #3 (PO3): Chub Lake – Helena 345 kV line

Finally, Table 8 below outlines the various faults that we analyzed for each of the above Outage Scenarios.

Table 8: Faults Analyzed

Name	Description
Fault_PI	5 Cycle 3 PH fault at PI
Chisago-345	5 Cycle Three phase fault at Chisago
Fault_eks	5 Cycle Three phase fault at King
Fault_odell	5 Cycle Three phase fault at CRANDAL
Fault_01s	5 Cycle Three phase fault at SherCo
Fault_05s	5 Cycle Three phase fault at Helena on Helena - Sheas Lake line
Fault_04s	4 Cycle Three phase fault at Chisago 500 kV
Monti-slf2	SLGF at Monticello
Monti-3ph2	5 Cycle Three phase fault at Monticello
Fault_pys	SLGF at PI
fault_02s	5 Cycle Three phase fault at Helena on Helena - Scott County line
Fault_03s	5 Cycle Three phase fault at Helena with common structure out
Fault_mcs	SLGBF fault at Sherco on Coon Creek #3 line with 8M40 Stuck
Fault_mts	SLGBF fault at Monticello with 8N6 stuck
Fault_pcs	SLG fault at King-Eau Claire line with a breaker failure at king
Fault_n03s	12 Cycle SLG fault at Red Rock 345 kv bus with failure of 8P24
Fault_mw3s	3 phase fault at Wilmarth on Wilmarth - Sheas Lake 345 kV line
Fault_mqs	SLGBF fault at Sherco on Unit #3
Fault_mjs	SLGBF fault at CHISAGO
Fault_m6s	5 Cycle 3 PH fault at Parkers Lake 345 kV
Fault_m5s	10 Cycle 3 PH fault at Coon Creek 345 kV bus with failure of 8M40
Fault_m4s	10 Cycle 3 PH fault at Terminal
3P_Terminal_TR9_B3s	3 phase fault at Terminal 345 kV bus, normal clearing
3P_Adams_Mitch	Three phase fault at Adams
3P_Briggs_NorthMad	Three phase fault at Briggs Road
3P_Brookings_Hawks	Three phase fault at Brookings County
3P_ChubFault_OpentoHelena	Three phase fault at Chub lake on Chub Lake - Helena line
3P_HelenaFault_OpentoChub	Three phase fault at Helena on Chub Lake - Helena line
3P_Lakefield_Huntly	Three phase fault on Lakefield JCt - Huntley line
3P_Lakefield_LakeJct	Three phase fault on Lakefield JCt - Lakefield line
3P_Lakefield_Obrien	Three phase fault on Lakefield JCt - Obrien line
3P_Sioux_SplitRock	Three phase fault on Sioux - Split Rock line
3P_Split_Nobles	Three phase fault on Split Rock - Nobles County line
SLG_Alexandria_BKR3325	SLG fault at Alexandria with breaker 3325 stuck
SLG_Hawksnest_8N82_Stuck	SLG fault at Hawksnest with breaker 8N82 stuck
SLG_Lakefield	SLG fault at Lakefield with breaker stuck
SLG_Wilmarth_8S23_Stuck	SLG fault at Wilmarth with breaker 8S23 stuck

b. Study 2 Results

In general, the lack of system margin from the significant absence of synchronous generation results in the inability of the system to recover from system events.

This lack of margin is also evident when analyzing the loss of a major transmission source to the Twin Cities Metro area. If enough of these sources are unavailable, the system can become unstable, even with non-NSP System baseload generation resources available as they are today. In addition to the reliability and stability implications of insufficient resource availability in the correct locations, heavy reliance on renewable resources located only in the highest capacity factor/highest concentration locations, such as southwestern Minnesota, results in a less resilient system. In these scenarios, utilizing the current transmission system creates a single point of failure that can result in an inability to operate the system. This further demonstrates that it is likely that significant transmission development will be necessary as current baseload generating resources retire and renewable resources take an increasingly large role on the Upper Midwest grid.

Table 9 below shows the results for the scenarios (Base, PO1, PO2, PO3) for each of the outage events – with the yellow highlights being thermal overloads. We note that in Summer Peak conditions for PO1 and PO2, the model could not converge toa solution, meaning significant upgrades would be required if only to create a stable enough system and enable the analysis of other system impacts.

Table 9: Thermal Overload Results

Facility	2023 SLL				2023 SH90				2023 SUM			
	Base	PO1	PO2	PO3	Base	PO1	PO2	PO3	Base	PO1	PO2	PO3
Helena – Scott County 345 kV	1078 MW	678 MW	N/A	1602 MW 118%*	1545.2 MW 118%*	1158.5 MW	N/A	2232.5 MW 173%	1737.3 MW 138%	No Solution	No Solution	2323 MW 188%
Helena – Chub Lake 345 kV	720 MW	394 MW	1391 MW	N/A	1001 MW	695.2 MW	1931 MW 117%	N/A	868.5 MW			N/A
Sheas Lake – Helena 345 kV	1040 MW	N/A	809 MW	905.4 MW	1125.3 MW	N/A	780.4 MW	930 MW	1721.8 MW 137%			1544.5 MW 125%

*The line rating is calculated based on the bus voltage

Similar to the thermal overloads above, Table 10 outlines the voltage violations in the same grid conditions, scenarios, and outage conditions. In this case, the violations occur only in summer peak conditions. However, again, there are two cases where the model was unable to solve the violation.

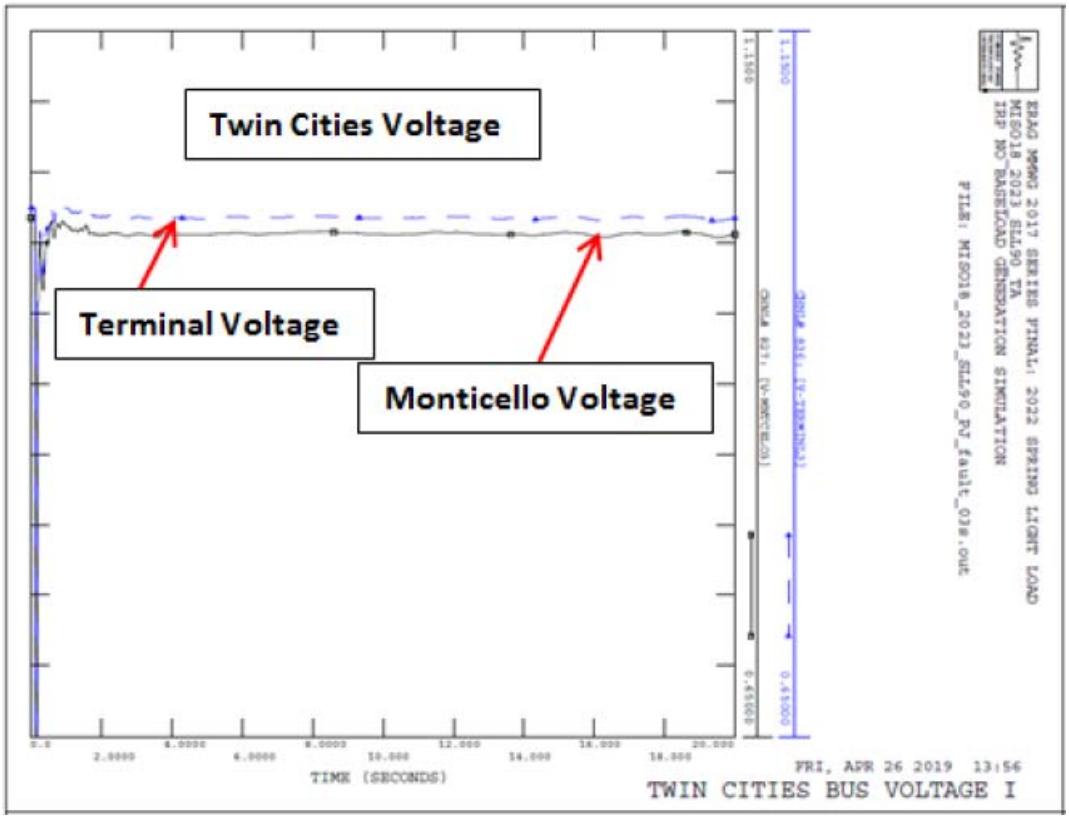
Table 10: Voltage Violation Results

Facility	2023 SLL				2023 SH90				2023 SUM			
	Base	PO1	PO2	PO3	Base	PO1	PO2	PO3	Base	PO1	PO2	PO3
Helena 345 kV	1.006	1.011	0.987	0.990	0.954	0.954	0.920	0.938	0.921	No Solution	No Solution	0.896
Sheas Lake 345 kV	1.001	1.006	0.986	0.988	0.951	0.978	0.924	0.938	0.917			0.898
Scott County 345 kV	1.015	1.017	1.016	0.999	0.968	0.972	0.975	0.948	0.940			0.910

As a result of increased reliance on renewable resources sited in locations to take advantage of higher capacity factors, the transmission system between those high capacity factor/concentration areas and areas of high energy usage become overly stressed, resulting in violations of facility ratings. As is the case in the summer peak scenarios, insufficient margin is available to come to a solution during higher demand scenarios.

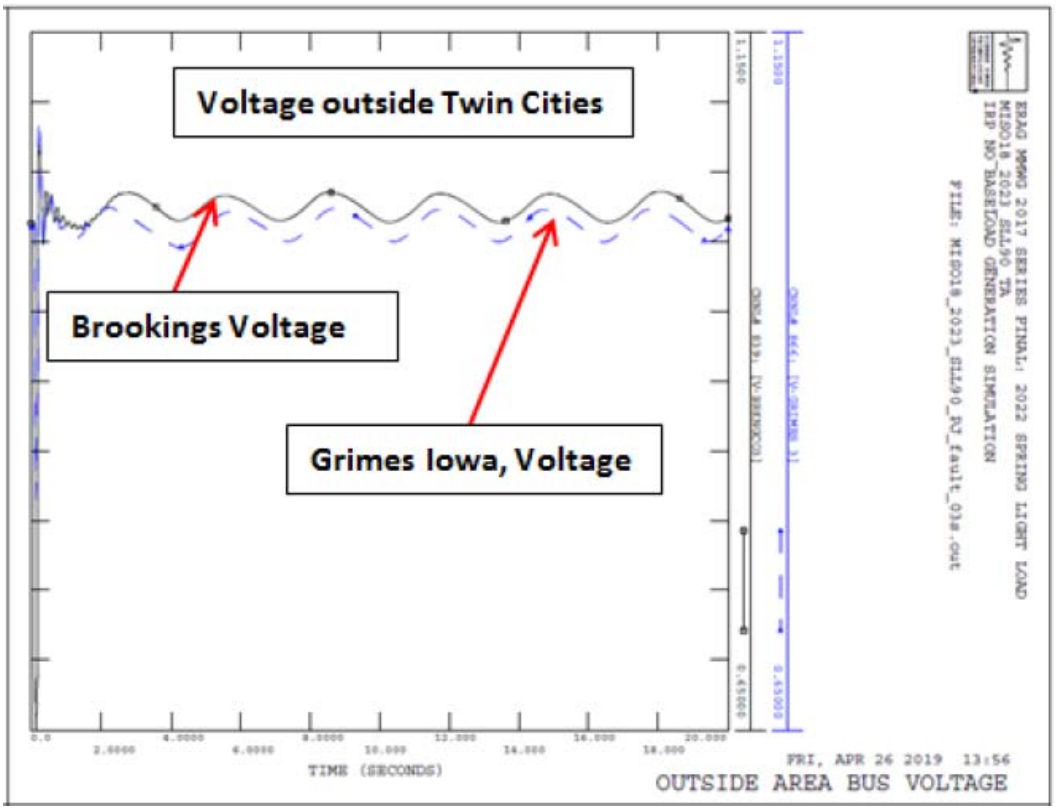
The stability plots in Figures 5 and 6 below show this effect. While the Twin Cities Metro area is able to mostly recover from an event, in all system disturbances tested, the ability of the system in southwest Minnesota and Iowa where there are large concentrations of renewables experience difficulty recovering voltage stability in light load cases.

Figure 5: Stability Plot – Insufficient System Damping
Twin Cities Metro Area Voltage



Damping is the flattening of the line as time progresses. Figure 5 above and Figure 6 below show that, while the Twin Cities Metro area can maintain stability, other areas outside of the Twin Cities Metro are unable to do so.

Figure 6: Stability Plot – Insufficient System Damping Outside Twin Cities Metro Area Voltage



While the scenarios developed for the light load cases were able to fully solve, despite some inability to remain stable, the summer scenarios with high levels of energy demand that are shown as "no solution" in yellow highlight in Tables 9 and 10 above resulted in system collapse due to insufficient resource margin available on the system to rebalance and regain stability after an event is experienced..

Figures 7 and 8 below demonstrate the system collapse, which is would result in widespread power outages and require black start procedures for MISO Load Resource Zone 1 to rejoin the grid once the system regained stability.

Figure 7: System Collapse – Summer 2023 P01 Case

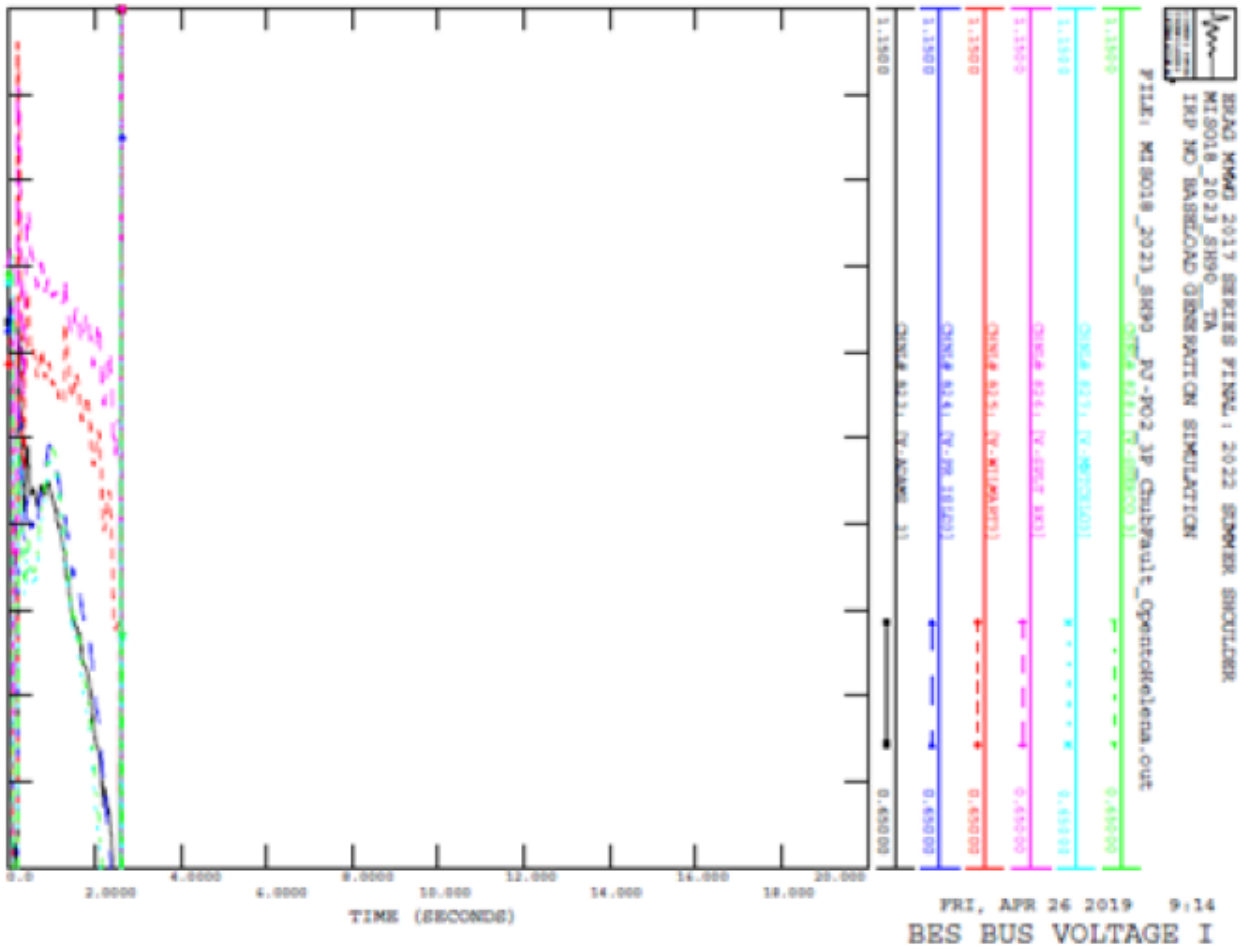


Figure 8: System Collapse – Summer 2023 P02 Case

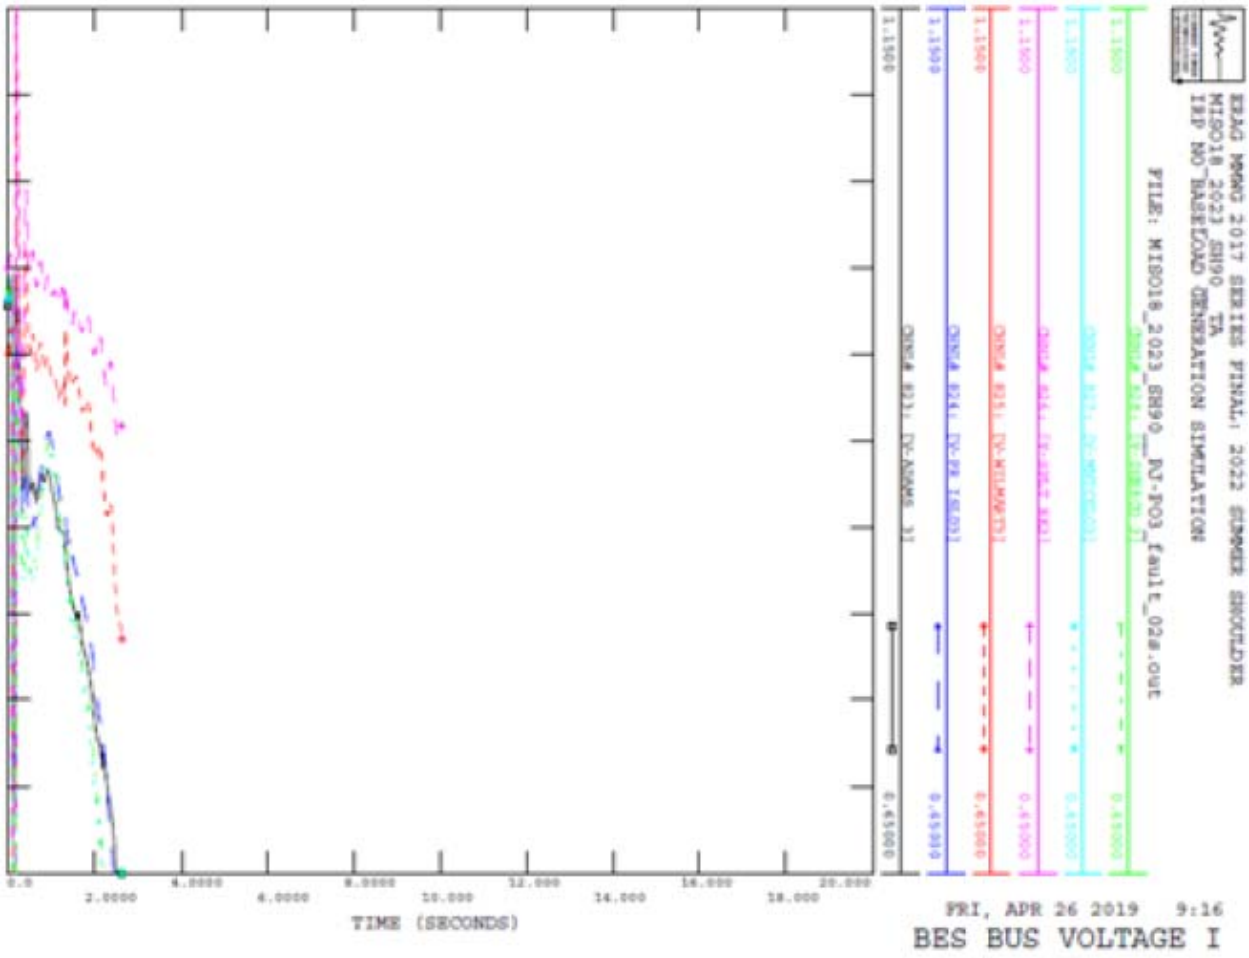


4. Summary of Results

As shown by the results of this analysis, the reduction in synchronous generation resources on the NSP System can have wide-ranging impacts on system stability and reliability. In particular, the retirement of NSP System baseload units without similar replacements at or near their current locations results in insufficient margin on the system during summer peak scenarios, and system instability in light load scenarios.

The lack of system margin results in the inability of the system to recovery from any of the system events analyzed in either the base summer peak scenario or the prior outage summer peak scenario. This lack of margin is also evident when analyzing the loss of a major source to the Twin Cities metro area. If enough of these sources are unavailable, the system can become unstable, even with non-NSP System base load generation resources available as they are today.

In addition to the reliability and stability implications of insufficient resource availability in the correct locations, heavy reliance on renewable resources located only in the highest capacity factor locations results in a less resilient system. In these scenarios, utilizing the current transmission system results in a single point of failure that can result in an inability to operate the system. Additional transmission development will likely be necessary to improve system resilience and facilitate increased levels of renewable resources in the Upper Midwest.

These two efforts help to better understand the impacts of increased baseload retirement on system stability and reliability trend toward the same conclusion. Without sufficient dispatchable and synchronous generation resources available to maintain sufficient margin, the system cannot remain stable resulting in even minor disturbances leading to the potential for cascading failures and system collapse. In addition, increased reliance on renewable resources without utilizing current interconnection rights and transmission system capabilities will result in significant transmission expansion required to maintain system reliability and ensure the safe, resilient and cost effective delivery of power.

G. Strategist Baseload Economic Analysis

To help inform our Preferred Plan with an economic view of an orderly, cost—effective baseload retirement schedule, we developed fifteen Strategist scenarios with varying combinations and timing of baseload unit retirements. These scenarios also identified the size, type, and timing of new resources needed to continue meeting customers' needs and achieve our 2030 carbon reduction goals.

We compared these scenarios to a Reference Scenario, which is essentially an extension of our most recent Resource Plan with respect to all of the baseload units retiring at their currently scheduled retirement dates.[31] These scenarios are generally grouped into "families," which we outline below. First, however, we summarize the retirement dates for the respective baseload units in the Table 11.

[31] The Scenarios and Sensitivities are discussed in Chapter 5: Economic Modeling Framework and Appendix F2: Strategist Modeling Assumptions & Inputs.

Table 11: Economic Analysis – Baseload Unit Retirement Date Assumptions

Baseload Unit	Current Schedule/ Reference Case	Early Retirement	Life/License Extension
A.S. King	2037	2028	NA
Sherco Unit 3	2040	2030	NA
Monticello	2030	2026	2040
Prairie Island Unit 1	2033	2024	2043
Prairie Island Unit 2	2034	2025	2044

Early Coal Family. These scenarios are designed to evaluate the economics of retiring King and/or Sherco 3 early.

- Scenario 2 *(Early King)* – King is retired early; Sherco 3 and the nuclear units are unchanged.
- Scenario 3 *(Early Sherco 3)* – Sherco 3 is retired early; King and the nuclear units are unchanged.
- Scenario 4 *(Early All Coal)* - King and Sherco 3 are retired early; the nuclear units are unchanged.

Early Nuclear Family. This family of scenarios is designed to test the economics of retiring Monticello and/or Prairie Island early, either alone or together – and with the combination of early coal retirements.

- Scenario 5 *(Early Monticello)* – Monticello is retired at the end of 2026; coal and Prairie Island are unchanged.
- Scenario 6 *(Early Prairie Island)* – Prairie Island is retired by the end of 2025; coal units and Monticello are unchanged.
- Scenario 7 *(Early All Nuclear)* – Prairie Island and Monticello are both retired early; coal units are unchanged.
- Scenario 8 *(Early All Baseload)* – All baseload units (coal and nuclear) are retired early.

Extend Nuclear Family. This family of scenario is designed to test the economics of re-licensing Monticello and/or Prairie Island and extending the operational life by ten years beyond the current end of license dates.

- Scenario 9 *(Early Coal, Extend Monticello)* – All coal is retired at the early dates; Monticello is extended for 10 years; Prairie Island is unchanged.

- Scenario 10 *(Early King, Extend Monticello)* – King is retired early; Monticello is extended for 10 years; Sherco 3 and Prairie Island are unchanged.
- Scenario 11 *(Early Coal, Extend Prairie Island)* – All coal is retired early; Prairie Island is extended for 10 years; Monticello is unchanged.
- Scenario 12 *(Early Coal, Extend All Nuclear)* – All coal is retired early; Monticello and Prairie Island are extended.
- Scenario 13 *(Extend Monticello)* –Monticello is extended; King, Sherco 3, and Prairie Island are unchanged.
- Scenario 14 *(Extend Prairie Island)* – Prairie Island is extended; King, Sherco 3, and Monticello are unchanged.
- Scenario 15 *(Extend All Nuclear)* – Both Monticello and Prairie Island are extended; King and Sherco 3 are unchanged.

After identifying the scenarios for analysis, we utilized the Strategist modeling tool to identify sets of resources needed to continue to meet customer needs for each scenario, along with their resultant costs and emissions impacts. We also included the planning level mitigation cost estimates from the MISO Y2 studies – and we applied the Reliability Requirement, discussed in detail in Appendix J2.

From a modeling perspective, the Present Value Revenue Requirement (PVRR) and Present Value Societal Cost (PVSC) results are primary indicators of the economics of various scenarios, or paths forward. The modeling indicated that the nuclear extension scenarios paired with early coal retirements yielded the most attractive present value compared to the Reference Case. This economic view of various options provided helpful insights that informed the Preferred Plan we propose in this Resource Plan, which correlates to Scenario 9.

In summary, the baseload retirement aspects of our Preferred Plan include:

(1) Retirement of our remaining two coal units early: King in 2028 (nine years early) and Sherco 3 in 2030 (ten years early).

(2) Operating our Monticello unit through 2040 (10 years longer than its current license) and operate both Prairie Island units through the end of their current licenses (PI Unit 1 to 2033 and PI Unit 2 to 2034).

We discuss results of our Strategist modeling in more detail in Chapter 4: Preferred Plan and Appendix F2: Strategist Modeling Assumptions & Inputs of this Resource Plan.

V. CONCLUSION

We believe the increasing trend toward a clean energy future, along with rapidly advancing technologies and aging generation assets will significantly change the generation mix in Minnesota and across the United States over the next 15-plus years. We have done a comprehensive analysis of the impacts of cost-effective and orderly retirement of our baseload fleet in compliance with the Commission's Order – and in support of our clean energy vision. The results of this Baseload Study informed the Preferred Plan we propose in this Resource Plan, which includes the following baseload actions: (1) Retire our remaining two coal units early – King in 2028 (nine years early) and Sherco 3 in 2030 (ten years early), and (2) Extend the operation of Monticello nuclear 10 years through a license extension, to 2040.

Through this work we believe the retirement of our current baseload units must be orderly, and will be impacted by decisions other MISO generation owners make regarding their baseload units. It will be important to maintain sufficient firm dispatchable, load supporting resources to support integration of renewable resources, and ensure customer reliability and system resilience. Changes in the MISO planning construct are necessary to properly recognize the inherent variable and intermittent nature of renewable resources in meeting customer needs every hour of every day. Finally, we also believe significant new regional transmission development will be necessary to support increased levels of renewable resources and to support the retirement of baseload units.

APPENDIX J2 – RELIABILITY REQUIREMENT

As the Company increases the amount of renewable generation on our system, it is important to recognize that these resources cannot alone reliably provide customers the energy they demand every hour of every day, or maintain the stability of the grid. Until such time as new technologies develop to fully transition the grid to carbon-free resources, some level of load-supporting, firm dispatchable resources is necessary for grid resilience and customer reliability.

As penetration of variable and intermittent resources like wind and solar increase on the grid, it requires a new planning paradigm. The traditional method of planning on a capacity-basis for a single system peak will no longer ensure we meet our customers' needs in every hour. Our planning needs to become energy-oriented and be able to match available generation and customer load as available resources and customer load go up and down every day. A winter peak, while much lower than summer, can be just as challenging to meet if we do not have sufficient resources at the time of the peak. The January 2019 polar vortex is an example of this – but severe winter weather is not the only time this issue can occur. As we discuss below, it can also occur on an otherwise normal winter or summer day.

This planning concern is not limited to the NSP System, but rather across all of MISO's footprint – and in other regions with increasing levels of renewables. Although MISO recognizes these challenges, its current planning constructs do not fully incorporate measures to address them. We have therefore developed a Reliability Requirement to inform this Resource Plan and mitigate risks to customer reliability and system resilience as MISO determines how to incorporate these issues into its planning process. The Reliability Requirement will ensure we have a sufficient level of dispatchable load supporting resources that can quickly respond to fill gaps between customer demand and energy supply at times of low or non-existent renewable generation. In short, it ensures that we can serve customers with reliable energy every hour of every day.

Below, we discuss the specific system conditions and events we believe call for the addition of the Reliability Requirement. We also discuss how we derived this requirement, and how we applied it in the modeling underlying this Resource Plan. Because the Reliability Requirement involves consideration of the level of market reliance we can reasonably depend on, we start with an overview of MISO and its resource zones.

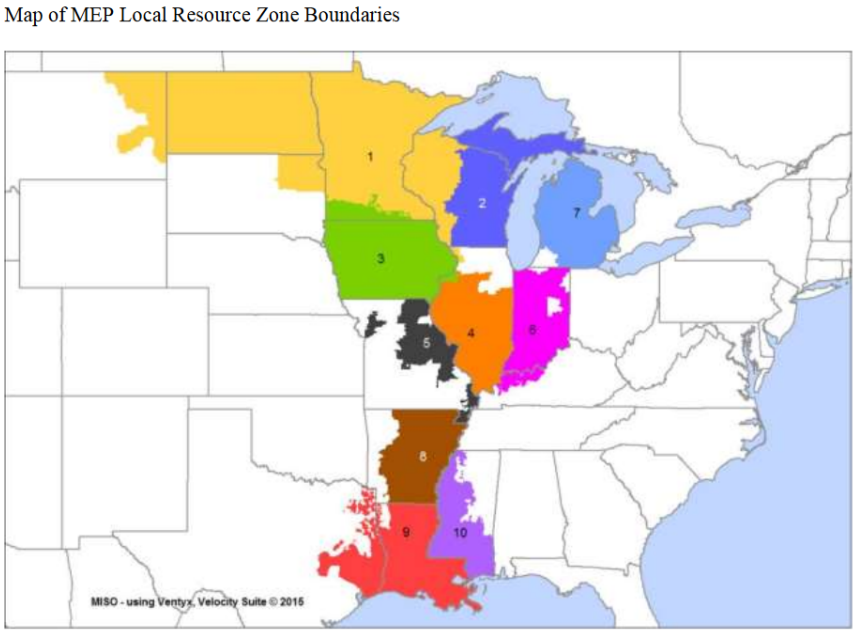
I. MIDCONTINENT INDEPENDENT SYSTEM OPERATOR OVERVIEW

The current wholesale energy market in MISO is a subsection of the Eastern Interconnection, which is the electric transmission grid that spans from the east coast of the United States to the central plains and from the Hudson Bay in Canada to the Gulf of Mexico. Wholesale energy markets, including MISO, rely on a large pool of resources with geographically diverse needs and resources that aim to allow excess resources in one part of the footprint to meet customer demand in another through use of the transmission grid. This diversity helps to mitigate the need to locate generation in close proximity to areas of demand, and can level variability in renewable resources by taking advantage of weather differences across the entire market's footprint.

While today's interconnected grid of transmission facilities reliably transfers large amounts of energy over long distances to meet customer demand, the grid was not originally developed to serve regular (*i.e.,* "base system") customer demand across distant geographies for significant durations throughout the year; nor was it designed to serve customers from densely-sited renewable generation, like it does now. And while these individual systems are interconnected, the there is not sufficient transmission infrastructure to be able to operate the MISO footprint like one of the original utility footprints. Therefore, one of the reliability measures that MISO instituted was to develop Local Resource Zones (LRZ) and inter-LRZ transfer limits to ensure ongoing reliable system operation.

The Figure below portrays the geographic diversity of the current MISO footprint and shows the different LRZs by number and color.

Figure 1: MISO Local Resource Zones



Source: Attachment WW of the MISO Tariff.

The NSP System is in LRZ1 along with Dairyland Power Cooperative, Great River Energy, Montana-Dakota Utilities, Minnesota Power, Ottertail Power Company, and Southern Minnesota Municipal Power Association.

This has worked well, however, the fundamental nature of the resource side of the equation is changing, which drastically changes the dynamics on the grid. There are more distributed, intermittent generating sources – and large synchronous generating units are retiring from the system. Inverter-connected resources at high levels of penetration generally do not provide the system services necessary for utilities to operate reliably. Without the inertia from the large generating units, system stability could be compromised – and the system is much more susceptible to the effects from what traditionally would have been inconsequential disturbances. As the level reliance on these interver-based resources continues to increase, new approaches to system planning are needed, as the current state of those processes cannot sufficiently address the differences in these resource types.

II. CURRENT MISO RENEWABLE CAPACITY VALUE DETERMINATIONS

On today's system, MISO has an annual processes to assign capacity values to generating resources that vary by resource type, and that establish resource adequacy

requirements for load serving entities such as the Company. These values come from the availability of the resource type as evaluated over a long base of operating experience at a specific hour of the year. The set of resources with specific performance attributes are put into a Loss of Load Expectation (LOLE) study and mixed with simultaneous probabilities (i.e. Monte Carlo type analyses) of when those outages may occur across the grid. This analysis also considers transmission performance capabilities and thus probabilities of loss of a transmission element. These analyses combine to ensure that the chosen resource mix and the specific grid will allow for load to be served to a load loss standard usually of no more than one day loss in 10 years. These capacity valuation mechanisms include the MISO Effective Load Carrying Capability (ELCC) analysis[1] and Wind and Solar Capacity report. The resource capacity values are commonly known as "accredited" amounts of capacity that can be relied upon to meet customer demand for planning purposes. MISO's resource adequacy process also establishes the margin by which the Company's resources are required to exceed demand in order to cover potential uncertainty in the availability of resources or level of demand.

If there are larger amounts of resources with the same performance attributes included in this analysis, the probability of loss of all those resources at the same time increases – and thus, the probability of impact on the load loss standard increases. For transmission for example, a consideration is the proportion of longer lines, which are more susceptible to weather or other types of disruptions, compared to shorter lines. As we discuss in more detail below, this is the reason that higher proportions of intermittent or variable resources erodes the capacity value for *more* of that resource – because the probabiblity of loss increases. Diversity in the type and location of a resource mix has always been important, and that will only become more important as the grid continues to evolve.

MISO's current resource adequacy requirements do not consider this expected marginal decline in load carrying capability from renewables as penetration increases, which we believe could ultimately result in a resource deficiency. The capacity accreditation also does not take into account the seasonal and weather-related variability that we have observed in both winter and summer instances, where renewables have vastly underperformed their expected contribution to load. In these circumstances, firm dispatchable, load supporting resources have been needed to fill the gap. Our Reliability Requirement is intended to recognize this new normal that is emerging. We outline the current MISO processes that determine resource adequacy requirements and capacity accreditation for wind and solar resources below.

[1] ELCC is a measure for estimating a resource's capacity value to meet customer needs with no net change in reliability.

A. Loss of Load Expectation Study

A Loss of Load Expectation (LOLE) study is intended to assess the overall probability that there will be a shortage of power, and is defined as the expected number of days per year for which the available generation capacity is insufficient to serve the demand at least once per day. The MISO LOLE is performed annually, analyzing a two-year horizon. From this study, several threshold requirements used in resource planning efforts are established for the following year – including a margin of resources the Company is required to maintain over and above its expected customer demand. This resource adequacy margin is the amount of generating capacity, over-and-above expected customer load that needs to be present on the system to ensure reliability in all but the most extreme circumstances; this margin does not however, currently account for the intermittent nature of renewable resources. As we describe below, renewable resources are assigned an accredited capacity value based on their annual average contribution to the system peak, rather than their ability to contribute to customer needs every hour of every day.

After these general obligations have been determined, we consider the type of resources suitable to meet that requirement. MISO's tariff and business practices set forth procedures to enable various types of resources to be used to achieve our requirement. These resources are referred to as "Planning Resources," which include the following sub-types:

- *Capacity Resources*: Physical Generation Resources (i.e. physical assets and purchase agreements), External Resources if located outside of MISO's footprint, and Demand Response (DR)resources participating in MISO's energy and operating reserves market, available during emergencies.
- *Load Modifying Resources*: Behind-the-Meter Generation and Demand Resources available during emergencies, which reduces the demand for energy supplies coming from the load-serving entity (LSE).
- *Energy Efficiency Resources*: Installed measures on retail customer facilities designed and tested to achieve a permanent reduction in electric energy usage while maintaining a comparable quality of service.

The Planning Reserve Margin (PRM) process establishes PRM values on both an installed capacity (ICAP) basis, which reflects the nameplate capacity of a resource, and on an unforced capacity (UCAP) basis, which incorporates the resource's operation, maintenance and utilization characteristics. Utility planning for system needs, including the planning we do as part of Minnesota Integrated Resource

Planning process, focuses on UCAP values, so we can plan to the measure of a resource's reliable contribution to system needs.

Physical generating resources and registered DR are assigned a UCAP value by applying a discount to their installed capacity. For a generator, the discount represents its forced outage rate. For DR, MISO uses a documented process of assessing the resource's observed responsiveness and effectiveness at reducing load. Intermittent Resources—including large-scale Solar, Wind, and Hydro–are assigned UCAP values that are determined by the individual unit's historical performance during the peak hours of the planning period.[2] As we discuss above, we are entering a new planning paradigm, and planning for a single system peak will no longer ensure customer reliability.

B. Wind and Solar Capacity Credit Report

Using the data from the LOLE study, MISO creates an annual Wind and Solar Capacity Credit Report that establishes MISO-wide capacity values for all wind and solar resources for the next planning year. MISO currently uses a probabilistic analysis as the first step in determining the ELCC for wind and solar resources. The second portion of the analysis utilizes a deterministic approach using historical wind resource output data, which incorporates the resource location. Combining these two sets of analyses, MISO then aggregates the characteristics to the nearest Commercial Pricing Node (CPNode) to determine a localized Wind Capacity Credit for each CPNode.

The 2018 report utilized installed wind capacity as of June 30, 2018, which included 18,210 MW of nameplate generating capacity assigned to 215 individual CPNodes. The values from this report are intended for incorporation into the following planning year – in this case, 2019. These values are as follows:

- Wind Capacity Credit (MISO system-wide):[3] 15.7%
- Solar Capacity Credit:[4] 50%

[2] Currently, these units are measured on historical performance during the operating hours of 1500 to 1700 in the months of June-August over the three most recent summers. Each site must have one complete historic period of data prior to unit accreditation.

[3] The calculation of the Wind Capacity Credit is the Individual CPNode Capacity Credit % = Peak Metric * K, where K is the coefficient representing the ratio between the calculated ELCC and the sum of the individual CPNode peak metrics.

[4] As of December 2018, MISO had a registered total of 313 MW of installed solar capacity. Because of the relatively low volume, MISO assigns each new solar unit a 50 percent capacity credit until additional operational data is available.

MISO also conducts studies on an LRZ-level to ensure regional reliability.

C. Relevant Regional Planning Considerations

MISO has the largest geographical footprint of any regional transmission organization. This provides valuable geographic diversity and access to additional resources when needed for back-up purposes. However, there are limitations on the amount of energy that can be shared between LRZs, and the amount of energy that can be imported or exported between MISO and other regional transmission organizations. As a result, MISO has developed localized studies that address the resources needed within each LRZ, as well as the limitations on transferring energy between LRZs, as follows:

- *Local Reliability Requirement.* This value is calculated to determine the amount of resource capacity needed on a LRZ level to ensure reliable service of customer demand during peak usage.
- *Capacity Transfer Limitations.* Capacity Import Limitation (CIL) and Capacity Export Limitation (CEL) values are determined through a capacity transfer study that signals the levels of capacity that can be both imported into a LRZ and exported to a LRZ while maintaining reliability.

Despite its broad geographic diversity, MISO remains susceptible to variations in resource availability based on, among other things, weather. As we have explained, today's interconnected grid is not the same as the traditional utility-specific grids that were built to serve local customer loads. There is not sufficient transmission infrastructure within MISO to transfer any resource type any distance – nor can it import limitless resources from other regional grids. Weather has taken out all of a certain type of resource – specifically wind, in the case of the 2019 polar vortex. Similarly, a day in July 2018 was an especially windless day and in one hour, the wind turbines that were online were taking more power than they were producing. This hour was also part of an approximately *110 hour* sustained stretch in which the combined output of all wind resources in the MISO footprint fell well below the accredited values used in present planning processes.

Individual utilities therefore must consider what level of reliance on the MISO market is reasonable to fulfill their system needs without exposing their customers to potential shortfalls or high prices, particularly in the event of high system stress conditions. We take our responsibility to ensure we have access to a sufficient level of resources in all grid conditions to meet our customers' needs seriously. The future

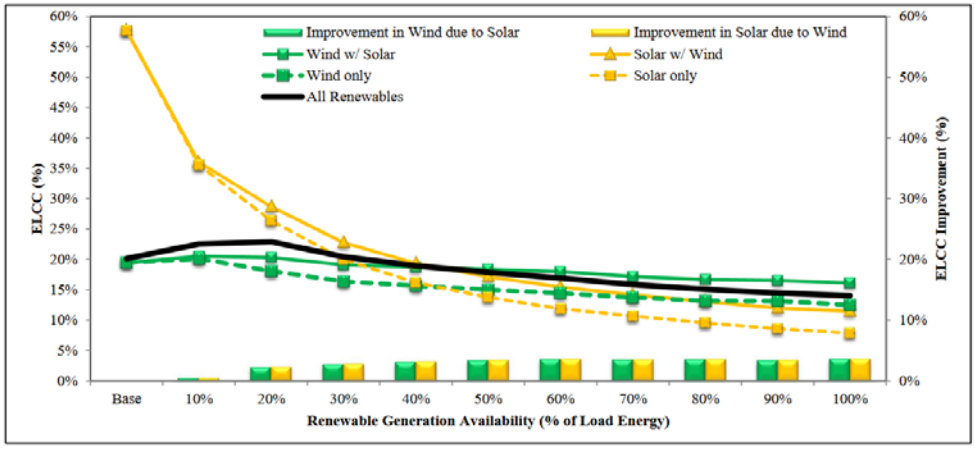
MISO grid will rebalance the new resource mix and the new transmission configuration needed to support it. We expect there will be many transitional stages between now and then to achieve this resource shift reliably. Determining our level of market reliance as part of our Reliability Requirement is a necessary part of this transition.

III. HIGH LEVELS OF RENEWABLES RESULT IN DECLINING CAPACITY VALUE

The industry is beginning to recognize and adapt planning processes to incorporate declining capacity values for wind and solar resources as penetration levels increase. However, MISO has not yet changed its planning processes to account for these limitations.

In 2017, MISO initiated its *Renewable Integration Impact Assessment* (RIIA) to examine issues surrounding effective integration of high levels of renewable resources. The figure shown below is an excerpt from an April 18, 2018 MISO presentation showing that, as wind and solar approach 100 percent penetration, their ELCC values decline significantly and approach 10 percent. When the generation fleet is diversified by including both wind and solar, the relative ELCC value for each is higher, but there is still a significant decrease in value as combined penetration approaches 100 percent.

Figure 2: MISO RIIA Study Finding –
Declining ELCC Value for Wind and Solar Resources



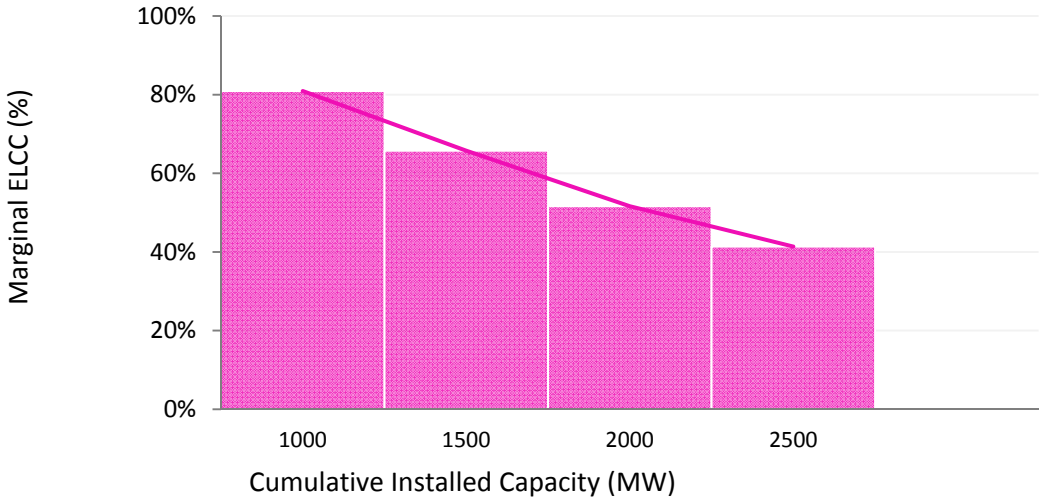
Source: MISO April 18, 2018 RIIA presentation at page 8.[5]

Notably, solar and wind are not the only resources whose capacity values decrease as

[5] https://cdn.misoenergy.org/20180418%20PAC%20Item%2003d%20RIIA174068.pdf

penetration increases. As shown in the analysis performed by E3 in connection with this Resource Plan, demand management programs also have decreasing relative effectiveness as participation increases.

Figure 3: E3 Marginal ELCC (%) – Four-Hour Demand Response



Source: E3 RECAP Analysis

Although early in the process and mainly focusing on their Resource Availability and Need (RAN) initiative,[6] MISO also recognizes that its current approach of using historical load shapes to predict the long-term future is no longer sufficient as Distributed Energy Resources (DER), Demand Response (DR), and energy efficiency become more prevalent. MISO likewise acknowledges that impact of these resources on demand, energy, and corresponding load shapes needs to be better understood and accounted for in its planning construct.

IV. RECENT ACTUAL LOW RENEWABLES PERFORMANCE EVENTS

In addition to these future planning – or accreditation – limitations, the actual performance of renewable resources reveals certain limitations with their ability to ensure reliability under all conditions and at all times without the support of some amount of dispatchable generation. To show this, we consider a number of actual case studies from the last 12 months below.

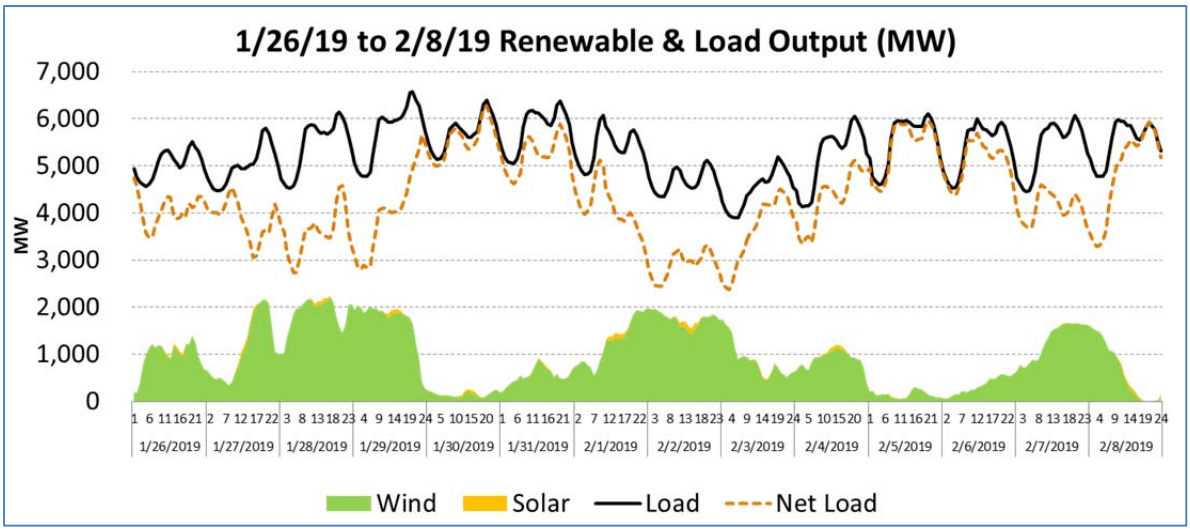
[6] The purpose of the MISO RAN initiative is to assure the conversion of committed capacity resources into sufficient energy every hour of the Planning Year.

A. Winter Case Study Events

In the past, winter months traditionally matched well with renewable resource production. In winter, we typically experience lower system demand and increased transfer capabilities, (meaning the ability to effectively transfer large amounts of renewable energy from where it is produced to load centers such as the Twin Cities Metro area). Additionally, wind resources generally achieve their highest efficiencies of the year over the winter months. However, as the penetration of renewable resources in the Company's fleet has increased and taken on a growing role in base energy production, winter has become an increasing concern. As we discuss below, during the 2019 polar vortex and an otherwise "normal" winter (and summer) day, firm dispatchable resources were needed to fill sustained periods of time where renewable resources were not producing at their accredited levels.

Given the variability of renewable generation, we have encountered times when the net customer load (which is the amount of customer demand not being met by renewable generation and for which firm dispatchable resources are needed) is near, or even equal to, the gross demand on the system. As shown below, this was the case during both the January 29-31, 2019 polar vortex, which was an extreme weather event marked by historically-severe and sustained cold temperatures combined with high winds, as well as February 5, 2019, a normal winter peak period.

Figure 4: Renewable Output and Load
January 26 – February 8, 2019



This illustrates why planning for a single system peak no longer works. We have to also plan to meet our customers' energy requirements on a net load basis – or the gap

between customer needs and variable resource availability every hour of every day.

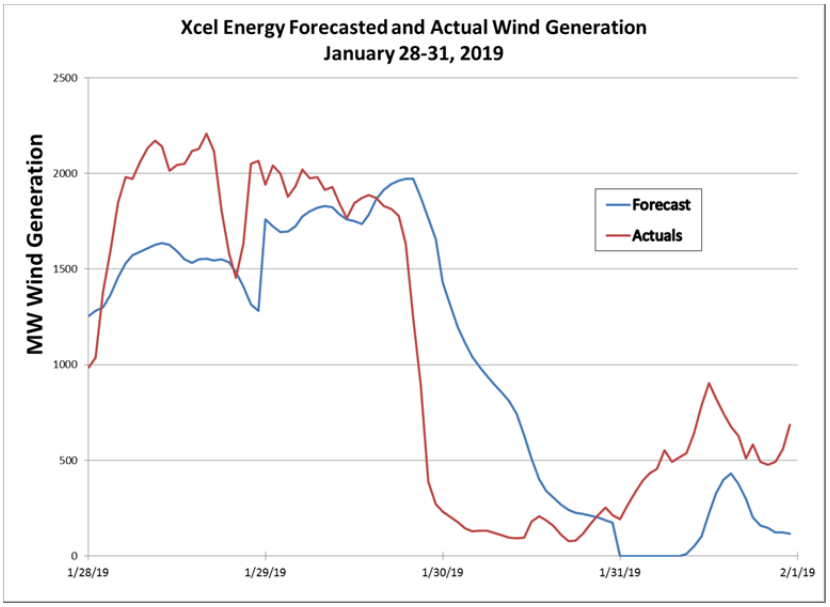
1. Extreme/Polar Vortex Event

The January 28 to February 1, 2019 timeframe, referred-to as the 2019 Polar Vortex, was marked by extreme cold temperatures over a sustained period of time across the northern United States, and specifically within the MISO footprint. The MISO region experienced ambient temperatures well below zero degrees Fahrenheit (F) for several consecutive days, with temperatures falling well below -20 degrees F in some areas. During this period, MISO experienced a resource deficiency and relied upon external resources and load control measures to reliably operate the system and balance generation resources with customer demand. Due to the duration and magnitude of the resource shortfall, neither DR nor energy storage could substantially contribute to reducing the Net Load.

The overwhelming majority of wind turbines now have operating temperature cutoffs at approximately -22 degrees F. MISO, however, did not have established measures to account for these limitations. As a result, and because of the high wind speeds during the polar vortex event, the MISO wind forecast projected upwards of 14 GW of wind generation to be online. However, the vast majority of wind turbines shut down in the early morning hours of January 30th, and output dropped to approximately 3 GW sooner than the forecast had predicted. As a result, firm dispatchable resources were needed to fill the gap left by the lack of wind.

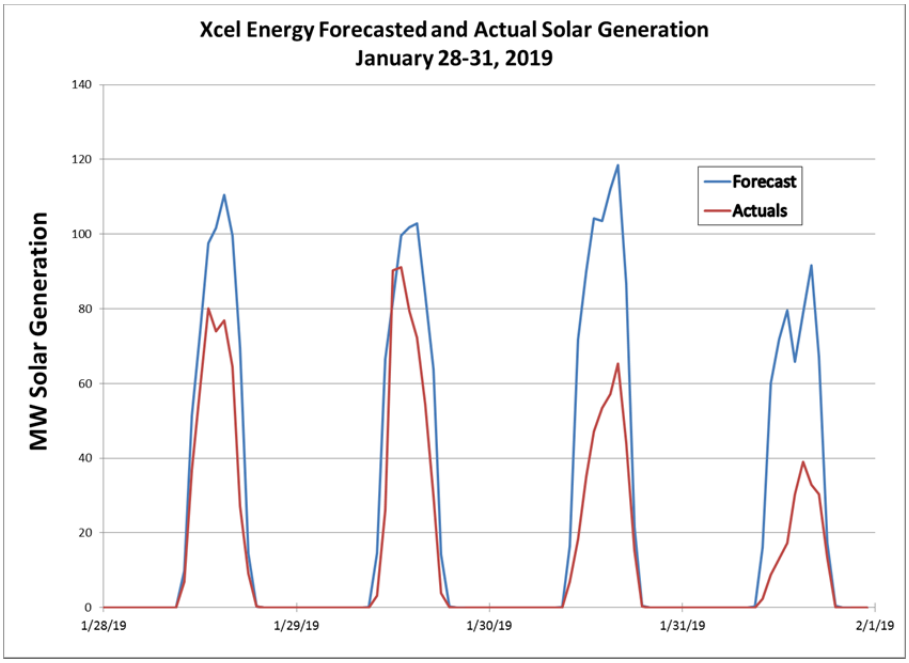
Figure 5 below shows the Xcel Energy wind actuals compared to the forecast during this period, which we note closely mirrored the MISO forecast and actuals.

Figure 5: Xcel Energy Wind Generation Actuals vs. Forecast
January 28-31, 2019



Solar generation performance is also affected by temperature, but does not involve cold weather cut-offs. Rather, solar panel efficiency drops off steadily once *panel* temperatures exceed approximately 42 degrees Celsius (107 Farenheit). Panel temperatures are typically approximately 20 degrees Celsius higher than the ambient air temperatures, thus solar production efficiency starts to decline when the ambient air temperature is in the range of 87-91 degrees Farenheit. PV Solar panel production works most efficiently during cold temperatures, with the obvious caveat that cloud cover and/or snow on the panels will reduce solar generation. We provide as Figure 6 below, a comparison of the Xcel Energy solar actuals compared to the forecast during the polar vortex period.

Figure 6: Xcel Energy Solar Generation Actuals vs. Forecast January 28-31, 2019



This solar forecast compared to actuals chart indicates a forecast error, especially for the last two days of the period. Our meteorologists attribute the error to a snow event at one of our larger solar facilities, where the conditions at the time were like those shown in Figure 7 below.

Figure 7: Snow Impacting a Large Solar Installation

Essentially, the solar panels that can "track" the sun are are built to maximize solar generation by continuously finding the optimal sun angle. Due to heavy snow in this situation, the panels were unable to move and the angle was insufficient to shed the snow cover, thus affecting actual production and not matching our forecast. In fixed-axis solar resources, there are options: (1) optimize to shed snow cover, which reduces the ability of that resource to produce energy; and, (2) optimize to output the most energy, which reduces its ability to shed snow cover. As we discuss below, winter solar performance is also affected by fewer light hours/shorter days and less optimal sun angles.

According to a report compiled by the MISO Independent Market Monitor (IMM), during this timeframe the MISO footprint used resource "reserves," which consisted of non-firm resources offered by neighboring regional transmission organizations into the MISO market. The level of these resources that MISO had to use to remain operational and avoid further emergency actions ranged from 5,000 MW to 11,500 MW – with an average of 6,500 MW on January 30th. The maximum offered reserve resources was 13,500 MW, which MISO nearly exhausted at one point in order to avoid a critical deficiency in available energy.

Although extreme, this weather event may reasonably be expected to occur again, and a disruption in electric service during a similar event in the future would have detrimental and serious impacts on our customers and public safety in general. We therefore believe this case study provides an important, recent example to consider as

we manage the transformation of our generation portfolio while prioritizing the reliability and stability of our system.

2. Normal Winter Day

In addition to cold temperatures affecting wind production, snow cover and icing also decrease wind and solar output in winter months; non-ideal sun angles and shorter days, and thus limited light hours, additionally impact solar production. While the polar vortex involved extreme weather conditions that affected wind production especially, February 5, 2019 was a normal winter day that offers another example where Gross Load was at, or near, Net Load (Gross Load minus contributing renewable resources) for a significant number of hours.

Between 7:00 a.m. and 11:00 p.m., there were 16 consecutive hours where Net Load was over 5,400 MW. Due to the duration and magnitude of this shortfall, neither DR nor energy storage could substantially contribute to reducing the Net Load, at least for the entire period. During this period, all wind and solar resources on the system combined to have an average hourly capacity factor of *six* percent, and there were particular hours when neither wind nor solar resources had a capacity factor greater than *three* percent. We provide the hourly capacity factors for wind and solar resources below.

Table 1: Hourly Wind and Solar Capacity Factors
February 5, 2019

Hour Ending	Wind Capacity Factor	Solar Capacity Factor
1	9%	0%
2	9%	0%
3	6%	0%
4	5%	0%
5	7%	0%
6	6%	0%
7	7%	0%
8	4%	0%
9	3%	0%
10	3%	3%
11	2%	6%
12	3%	6%
13	3%	5%
14	7%	5%
15	12%	4%
16	13%	2%
17	11%	1%
18	11%	0%
19	9%	0%
20	6%	0%
21	5%	0%
22	4%	0%
23	3%	0%
24	4%	0%

Because we currently have access to sufficient baseload and firm dispatchable resources on our system, we were able to serve customers reliably and affordably throughout the duration of this period.

3. Other Winter Conditions

In considering the resources available during periods of low wind generation, the Company also needs to assess availability of resources across MISO. The MISO footprint encompasses large areas that experience snow cover and extreme low temperatures in the winter months. This impacts the output of renewable resources throughout MISO in several ways.

Wind turbines are designed to cut-out at extreme cold temperatures to protect their operational mechanisms. During the 2019 Polar Vortex, temperatures dropped below the -22 degree F cutoff, causing wide-spread reduction of wind resources despite relatively high wind speeds.

Snow cover and icing negatively impact solar and wind generation resources. As discussed above, during the winter months in the Upper Midwest, snow and ice cover on solar panels significantly decreases the energy capabilities of those resources. Wind turbines are susceptible to blade icing, which causes decreased output or complete cessation. While these issues are limited to certain geographical areas, those same areas highly correlate with the most dense and highest average capacity-factor renewable resources in the MISO footprint.

Limited light hours combined with non-ideal sun angles reduce the output of solar resources in winter months. These conditions are prevalent throughout the MISO footprint, which combine to reduce the output of solar resources to fewer hours of the day, and lower levels of energy output when the sun is available.

B. Normal Winter Day Case Study Extrapolated to Higher Levels of Renewables

Consistent with our vision for 100 percent carbon-free energy in 2050, we studied these scenarios with higher levels of renewable resources than exist today. To do so, we replicated the operational scenarios encountered on February 5, 2019, but modeled with 5,000 MW of nameplate capacity wind and 5,000 MW of nameplate capacity solar resources. The results were very similar. For 13 of the 16 hours, the Net Load remained above 5,300 MW and all hours exceeded 5,000 MW of Net Load.

C. Non-Winter Case Study Event

Because low temperatures and other conditions unique to winter are not the only cause of low renewable generation in MISO, we also looked to the summer months as potential case studies. July 29, 2018 was an especially windless day. During the 8:00 a.m. hour, the entire MISO wind portfolio (over 17,000 MW at that time) had a combined output of *minus* 11 MW – meaning the wind turbines that were online were taking more power than they were producing. This hour was part of an approximately *110 hour* sustained stretch in which the combined output of all wind resources in the MISO footprint fell well below the accredited values used in present planning processes. We again encountered sustained low wind conditions in early 2019, with 370 hours of wind production below accredited values before May 1.

These case studies are supported by a recent University of Minnesota Research Brief about an initiative that examined conversion of home heating from gas to electricity – and supplying that electricity with renewable energy, which had been identified as a critical national decarbonization pathway.[7] The May 8, 2019 *Research Brief: Planning for the future of energy demand with renewable energy* reported that researchers at the University of Minnesota and three other institutions sought to understand whether enough renewable energy can be generated locally to meet most, if not all, of that increased electricity demand.

Researchers mapped out three scenarios: one that included battery and thermal energy storage options; an option that assumes no storage; and an option that overbuilds renewable supply by 150 percent of demand. They then ran models using data from four cities in three different climate zones, including Minneapolis, Minnesota.[8] The study found that for scenarios without storage, wind-based supply dominates the optimal mix for Minneapolis. The study also found that when 12-hour storage is available, renewable penetration increases from 54 percent to 70 percent in Minneapolis. In light of these findings, the Brief stated:

> However, no matter the scenario, the study found that the use of fossil fuels would still be needed to meet peak demand in cold climates like Minneapolis and Fort Collins. This is because renewable energy cannot be produced at the rate needed to meet demand during the coldest months..

Finally, the Brief reported that researchers suggest policymakers and/or low carbon energy system planners do the following:

- Take into account the geographic and climatic differences when finding the optimal mix of wind and solar generation,
- Consider incentives to invest in battery storage systems, which will increase the overall amount of demand that can be met with renewables,
- Count on a smaller, but nonetheless important, role for fossil fuel plants to meet peak demand.

V. KEY TAKEAWAYS

As this data shows, today's intermittent generating resources cannot alone meet

[7] *See* https://twin-cities.umn.edu/news-events/research-brief-planning-future-energy-demand-renewable-energy

[8] Other cities were New York City, New York, Fort Collins, Colorado, and Tallahassee, Florida.

demand at all times of the year, at least without excessive costs.[9] Even during historically good times of the year for renewable generation on the Company's system, the availability of these resources is inexorably tied to the variability of weather patterns, and at times they are simply not available.

Additionally, current storage technologies and demand management programs are also insufficient to meet the duration of real events like those discussed above. Current battery storage systems are limited (typically to 4 hour discharge periods) with significant time needed to recharge. Unless overbuilt many times over, these resources would not be able to provide energy for the full duration of such events; they also may not be able to recharge fast enough to be a viable resource during the consecutive periods of low renewable output. Similarly, and as discussed above, some of the most significant current demand management programs are specifically designed to reduce capacity needs during the system's overall peak during summer hours, and they would not be as effective, or effective at all, during winter periods.

These case studies and industry insights have highlighted gaps in present MISO planning constructs that – until MISO adapts – we must take into account to ensure system resilience and customer reliability. Fundamentally, we have a responsibility to ensure we have access to a sufficient level of firm dispatchable resources in all grid conditions that can flexibly adapt to variable renewable resource performance to meet our customers' needs. We take this responsibility seriously. We view these case studies as highlighting gaps in the present MISO planning construct. Until MISO determines how best to address these gaps, we believe it is incumbent on us as the utility to take steps to ensure that our system is resilient, that our customers will be reliably served, and that our customers are reasonably protected from high financial exposure in the market when the system is under stress.

VI. DEVELOPING THE RELIABILITY REQUIREMENT

In an effort to mitigate resilience and reliability risks, we analyzed the data from these case studies and created a reliability requirement for our modeling that reflects a reasonable amount of reliance on MISO resources and demand response to meet our system needs. The intent of this requirement is to supplement our system planning process to ensure we have sufficient resources available to reliably serve our

[9] Simply increasing the amount of solar and wind generation on the Company's system is an unrealistic approach to addressing capacity shortfalls. In order to have sufficient capacity to meet the customer demand discussed in the scenarios above, the Company would need in excess of 180,000 MW of nameplate capacity wind and solar generation. And, even this amount of renewable generation may be insufficient given the declining capacity value of renewable generation, as discussed above, and the probability there will be times with extremely low levels of wind and sunlight.

customers' energy needs every hour of every day – regardless of weather.

Establishing this reliability requirement involves a number of steps:

1. Establishing a level of peak demand to serve as a proxy for the most likely conditions where we would expect to have a gap between renewables performance and customer load.
2. Assessing the contribution we can reasonably expect from duration-limited resources like DR or energy storage to fill-in the gap.
3. Determining the extent to which it is reasonable, from a financial and operational risk perspective, to rely on the MISO market to make-up at least a portion of the gap.
4. Using these inputs to derive the level, of firm dispatchable resources that are needed to reasonably assure reliability. It is this level of firm dispatchable resources that ultimately forms the Reliability Requirement that we incorporated into our modeling for this Resource Plan.

We discuss the components of this calculation below.

A. Proxy Peak Demand

The first step in determining the Reliability Requirement was to approximate the customer peak demand we should expect during inevitable high stress MISO market scenarios. Although winter is not the only season in which we have experienced low renewable output relative to expected contributions, it is when we most expect weather conditions to impact wind turbine and solar panel performance (i.e. blade icing and snow cover). We therefore determined that the NSP System winter peak demand – or approximately 6,400 MW – would be an appropriate proxy and starting point to ultimately determine the resource types and amounts that we can reasonably rely on to fill the gap.

B. The Role of Duration-Limited Resources

Today, the Company is able to draw on DR and likely in the future, other time-limited resources such as storage to meet our customer needs. But, while these resources can help fill the gap to some extent, it would not be prudent or practical to fully rely on them to guarantee system reliability.

As discussed above, demand management programs have lower availability in winter months. As with all components of the Reliability Requirement, the DR proxy was

designed to avoid unrealistic assumptions of demand response availability. This proxy, therefore, allows for the support of demand management programs up to the point where they can no longer be considered firm resources. We included a demand response proxy of approximately 200 MW in our modeling.

C. MISO Market Reliance

As noted above, resources from the MISO market may also be available to fill the gap between customer load and low renewables performance, although transfers within and between LRZs are constrained in accordance with MISO's identified system capabilities. This is a valuable benefit of being part of a regional market. However, we expect that that other resources and loads in MISO and LRZ1 will experience similar conditions – particularly if an event is weather-related. We do not believe it would be reasonable or in our customers' best interest to rely on the market to fulfill the resource gaps caused by the unavailability of intermittent resources – especially in high-stress scenarios. It is therefore important to determine an appropriate and reasonable level of reliance on market resources during a high-stress scenario. Notably, these high stress times frequently happen in periods of extreme cold when our system is even more critical than normal. This market reliance issue will only become more important as utilities retire firm dispatchable resources that today aid reliability during these times of system stress.

Using a combination of MISO planning data and the IMM analysis of excess resources during the 2019 Polar Vortex event, we derived a level of MISO market reliance for the NSP System to incorporate into our RRP calculation.

Table 2: Planning Parameters to Derive NSP System Level of Market Reliance – High Stress Scenarios

Relevant Planning Parameter	2019-2020 Planning Year Values
MISO Peak Demand	125,501 MW
LRZ1 Peak Demand	17,780 MW
NSP System Peak Demand	9,129 MW
NSP System Peak as Percent of MISO	*7.27%*
NSP System Peak as Percent of LRZ1	*51.3%*
Polar Vortex Event – Minimum Excess Resources	5,000 MW
Polar Vortex Event – Average Excess Resources	6,500 MW
NSP System Share of Excess Resources (7.27% of Min. and Avg. Excess Resources)	364-473 MW
NSP System Market Reliance Level	**500 MW**

From the IMM analysis of the 2019 Polar Vortex event, we know the minimum (5,000 MW) and the average (6,500 MW) MISO-wide excess resources that were used during this event. These are important values to understand, as they were the level of excess non-firm resources made available from outside of MISO and needed by MISO to avoid a critical energy deficiency.

If similar operational events and system demands were experienced across large areas of the full MISO footprint during a high-stress event, and assuming that reliance on external resources would be split based roughly on each utility's portion of total demand, the Company would be able to rely on only 7.27 percent of any excess generation in the MISO system. Therefore, to derive the NSP System share, we applied the NSP System load ratio share to the minimum and average levels of excess resources from this event, which equates to a minimum of 364 MW and an average of 473 MW. From here, we assumed some additional customer efficiency might lower our peak or operational efficiencies might increase external energy available to the NSP System, and thus determined that 500 MW would be a reasonable level of MISO market reliance during a high stress scenario.

After approximating the contribution from these sources, we are able to determine the quantity of firm, dispatchable resources we need to maintain on the NSP System to assure reliability.

D. Some Level of Load Supporting Resources are Needed

The calculation of the Reliability Requirement results in a minimum level of firm

dispatchable resources necessary to adequately support customer loads. We discuss how we apply the Requirement to our modeling in Chapter 3: Minimum System Needs. We clarify here however, that while this concept is essential until MISO evolves its capacity construct, the Requirement has little effect in our modeling for this Resource Plan. The model does not select any firm dispatchable additions as a direct result of the Reliability Requirement until 2031, which is near the end of the planning period. This long runway leaves ample time for MISO and its stakeholders to address this aspect of its planning and provide additional direction.

That said, we demonstrate the calculation of the Requirement we applied in our modeling for this Plan in Figure 8 below.

Figure 8: NSP System Reliability Requirement Calculation – 2020 Example

Peak Demand Proxy – 6,400 MW
Minus Firm DR (Winter) Proxy – (200 MW)
Minus Firm Market Supply Proxy – (500 MW)

Reliability Requirement – 5,700MW
(Firm dispatchable resources)

We are confident that this is a reasonable and appropriate approach to determining a minimum level of firm dispatchable, load supporting resources necessary to maintain a reliable supply of power during high-impact low-frequency events like the 2019 Polar Vortex – as well as other typical summer or winter weather days that happen to have low renewable performance.

VII. SUMMARY

As the Company increases the amount of renewable generation in our system, it is important to recognize that these resources cannot alone reliably provide customers the energy they demand every hour of every day – or maintain the stability of the grid. MISO is beginning to recognize these challenges and that its current planning constructs do not yet address these issues. In the interim, our Reliability Requirement ensures we have the right mix of resources on our system every hour of every day to meet our customers' needs.

PUBLIC DOCUMENT
NOT PUBLIC DATA EXCISED

Attachment J3 is marked as "Non-Public" in its entirety and is provided with Critical Energy Infrastructure Information (CEII) redacted. Attachment J3 contains information regarding the MISO area grid, including specific information about the Xcel Energy and other transmission owner systems as it relates to the potential retirement of Xcel Energy's Allen S. King and Sherburne County Generating Plant (Sherco) Unit 3. While MISO has redacted all CEII from the report, Xcel Energy maintains that the balance of the information is "security information" as defined by Minn. Stat. § 13.37, subd. 1(a).

Pursuant to Minn. R. 7829.0500, subp. 3, the Company provides the following description of the excised material:

APPENDIX K – XCEL ENERGY RESOURCES: NUCLEAR

I. NUCLEAR

Carbon-free nuclear generation has been a cornerstone of our generation fleet for nearly fifty years, and its continued role on our system is critical to ensuring that we continue to make progress in reducing our carbon emissions. Our Preferred Plan therefore includes the extension of operations at the Monticello nuclear plant until 2040, along with the continued operation of Prairie Island through its current operating licenses (which expire outside the planning period in 2033 and 2034). By continuing the operation of these plants and extending our Monticello license, we can continue to drive the substantial carbon-free benefits that our nuclear fleet provides while saving our customers money by leveraging existing assets on our system that are leading the industry in terms of performance.

In this section, we discuss the importance of our nuclear generation fleet to our environmental and resource planning objectives. We also provide an update on the strong performance of our nuclear fleet since our 2015 Resource Plan, as well as our capital and O&M forecasts, and we discuss the results of our Strategist modeling in connection with our nuclear strategy. Finally, we discuss the economic, community, and employment benefits associated with relicensing Monticello, and we outline the regulatory processes associated with relicensing at the NRC and seeking authorization from this Commission to obtain additional dry fuel storage capacity to support extended operations.

A. Nuclear's Role in Reducing Carbon Emissions

Xcel Energy has been on the path toward significant carbon reduction for more than a decade and, since 2005, we have reduced carbon emissions 38 percent company-wide. In order to achieve our goal of an 80 percent reduction of carbon emissions by 2030, we need to retire our coal-fired generation before 2030, replace those assets with low- or no-carbon resources, and preserve the carbon-free generation that is already part of our system. Our Monticello and Prairie Island nuclear plants—which total 1,688 MWs in baseload capacity—comprise more than half of our existing carbon-free generation and one-third of our total generation. Our reliance on these

plants avoids the emission of 7 million tons of carbon dioxide each year, which is equivalent to removing 1.5 million cars from the road (or more than 20 percent of all registered vehicles in Minnesota as of 2016).

The Company simply cannot achieve similar levels of carbon reduction without nuclear generation on our system. As discussed in our Baseload Study, we will need a significant amount of firm dispatchable generation on our system in order to ensure around-the-clock reliability as we move toward a portfolio that is predominantly renewable and intermittent. We therefore believe any near- or medium-term replacement of our nuclear resources would require some amount of incremental natural gas generation, which would negatively impact our progress on reducing carbon emissions. Moreover, given MISO's current transmission expansion issues, it is far from certain that we could get sufficient renewable projects through the MISO queue in time to replace our nuclear resources. And even if that were possible, it would require substantial renewable additions beyond those already contemplated in our plan, along with supporting transmission infrastructure. Replacing the carbon free energy from Monticello with renewable resources would require over 1,000 MW of wind or nearly 3,000 MW of solar resources along with $400 million in additional transmission investment based on our Resource Plan assumptions. Additionally, these energy only replacement estimates do not account for additional capacity costs that may be required to firm the renewable replacement or local reliability costs that would be required in the event of a Monticello retirement. The costs of adding these resources would have a significant impact on the overall cost of our Preferred Plan and would very likely jeopardize our ability to achieve the carbon reductions we envision.

We recognize that technological developments like energy storage hold great promise and that reliable, renewable baseload energy may be on the horizon. Like others, we are excited by storage technology and its potential to further transform our system, and we are taking steps as part of this Resource Plan to ensure that we are prepared to take full advantage of better technology in the future. But these technologies are still developing and, while approaching economic on a smaller scale, are not yet economic at a scale amounting to even a fraction of our nuclear fleet. For this reason, we view nuclear as a resource that will facilitate our transition to even greater renewable

generation and storage opportunities in the longer term, while we continue to pursue aggressive carbon reduction in the near-term.

Meanwhile, our nuclear fleet adds important diversity to our generation portfolio and provides a hedge against not only gas price volatility but also the uncertainty of technological development, future renewable pricing, and the future of solar capacity values. It is also a critical piece of our reliability requirement, as it is not a fuel limited resource, is not subject to pipeline limitations during the winter season, and has a strong operating history during cold (and hot) weather events. Indeed, our nuclear fleet operated at 100 percent capacity factor from January through April of 2018 and again in early 2019 during the Polar Vortex, before Monticello began to coast down in advance of its April refueling outage. Similarly, the summer months of 2018 and thus far of 2019 saw the nuclear fleet operating at full power during peak summer loads.

B. Flexible Operations Pilot

In addition to providing the carbon-free baseload energy we have relied upon for nearly 50 years, we also believe our nuclear units can be operated more flexibly in the future to complement a generation portfolio that will be predominantly renewable. In fact, we are currently piloting an operational strategy to reduce the power output of our nuclear plants when wind and solar resources are generating significant energy.[1] Historically, natural gas plants and, more recently, coal units have been "ramped" up and down to balance energy demands with the amount of renewable energy available on the system at a given time. For decades, nuclear plants have been considered "must-run" baseload power in the context of the MISO regional power market, and we therefore have focused on running at maximum power around the clock. Today, given the increasing additions of renewable resources on our system, we believe our nuclear plants can provide additional value if they can be ramped down during periods of high congestion and low prices. By doing so, the Company can take full advantage of the renewable resources on its system—both now and in the future—and can deliver even greater value from our carbon-free nuclear plants.

[1] We are also part of an industry working group on Flexible Power Operations at EPRI to gain insight from around the industry on this issue.

In 2018, the Company launched an initiative to demonstrate our nuclear fleet's ability to enter MISO's "Day Ahead" market and successfully maneuver one unit at Prairie Island between 75 percent and 100 percent power. Working with MISO, Prairie Island Unit 2 maneuvered through a series of power adjustment and simulated its participation in the Day-Ahead market, and we have since demonstrated similar operational flexibility at Prairie Island Unit 1 and Monticello. In fact, Prairie Island Unit 1 is already participating in the MISO Day Ahead market, and we expect Monticello to join that market in September and Prairie Island Unit 2 to join it in the fall after its refueling outage. In total, this means we will be able to ramp our nuclear fleet by approximately 400 MW, which will add significant operational flexibility to our overall fleet.

We believe the timing of this transition in our nuclear operations is aligned with the Company's plans to incorporate significant wind additions over the next two years, as we complete the build-out of our 1,550 MW Wind Portfolio and our Dakota Range facility. Nuclear has proven its value as the foundation of our baseload fleet, and its carbon-free generation make it a critical part of our plan to achieve an 80 percent reduction in carbon emissions by 2030. We view flexible power operations as an expansion of nuclear's role in our fleet and in the Company's efforts to integrate substantial amounts of renewable additions during the planning period.[2]

C. Performance & Costs

More than ever, we understand that the future of our nuclear fleet depends on our ability to deliver performance at a reasonable cost. Since our 2015 Resource Plan, we have undertaken substantial efforts to adopt wide-scale changes in the way we approach plant operations —with the goal of "bending the cost curve". And with the assistance of third-party consultants with expertise in both nuclear operations and general cost containment and efficiency strategies, as well as our continued work with the Institute of Nuclear Power Operations (INPO) and Nuclear Energy Institute (NEI), we have achieved industry-leading results not only in the performance of our

[2] We are also in the early stages of exploring the possibility of using nuclear energy to produce hydrogen, which in turn could be used both in the transportation sector and as energy storage. Xcel Energy has partnered with two other utilities to explore the economics and overall feasibility of nuclear-driven hydrogen production, and an $8 million funding request is currently pending with the Department of Energy's Light Water Reactor Sustainability Group.

nuclear plants but also in the costs we are investing to achieve that performance. In short, our nuclear plants have never operated on a more consistent, efficient, and safe basis.

1. Safety

Beginning with safety, the NRC Reactor Oversight Process classifies U.S. nuclear reactors into various "Columns," which range from 1 (best) to 5 (worst). Both Monticello and Prairie Island are Column 1 plants with all green performance indicators. And while no plant can achieve the standards of perfection imposed by the NRC at all times over its operational life, we believe our track record demonstrates the Company's longstanding commitment to nuclear safety. Further, during the 2R30 refueling outage in 2017, Prairie Island achieved its best industrial safety record (no OSHA or First Aid injuries) and the lowest occupational radiation exposure in plant history, and both plants have received the Governor's annual safety award for several years running.

2. Capacity Factor

With respect to plant availability, Monticello achieved an average capacity factor of 96.5 percent over the past three years, including a record-setting 99.3 percent in 2018. Likewise, Prairie Island achieved a combined average capacity factor of more than 90 percent over the past three years, including a 100 percent capacity factor for Unit 2 in 2018. This data reflects strong and improved performance at both plants, and the increased availability of our plants drives substantial customer benefits given the fixed costs associated with nuclear fuel. Contributing to these capacity factors was improved performance during plant refueling outages, which were completed on time and on budget. For example, in 2017, Prairie Island's Unit 2 achieved a 37-day refueling outage, which is that unit's shortest refueling duration in 10 years. Likewise, we have experienced some of the longest runs of uninterrupted operation in the history of our nuclear fleet, including a record-setting 499 days at Prairie Island Unit 1 in 2016-2017, and a current run of 583 days (as of June 27, 2019) at Prairie Island Unit 2. In fact, Prairie Island Unit 2 is currently on the third longest run in plant history.

3. O&M and Production Costs

Importantly, we have achieved these safety and operational results without increasing our production costs. In fact, both O&M and total production costs at our plants have decreased significantly in recent years. Total O&M for our nuclear fleet went down by $7 million between 2015 and 2016. It then decreased again by another $26 million in 2017, and decreased yet again in 2018 by another $8 million.

In terms of production costs (fuel plus O&M) per MWh, we achieved reductions of more than 20 percent between 2015 and 2018.[3] Specifically, our fleet average nuclear production costs have gone from $37.86 per MWh in 2015 down to $29.44 in 2018 (Prairie Island has gone from $37.08 down to $28.53, and Monticello has gone from $39.11 down to $30.91).

Contributing to these results has been Xcel Energy's commitment to driving efficiency through its XE1 initiative, which focused on process development and refinement and the integration of technology to achieve efficiencies. Industry experience shows that successful nuclear organizations are highly process and outcome driven and that focused process improvement has the benefit of driving down costs while at the same time improving plant performance. Through our work with the external consultants and INPO, we have been able to effectively improve upon a number of processes and personnel behaviors that has enabled the plant to achieve better results with fewer resources.

4. Capital

We have also completed a long-term re-analysis of our capital budgets for both Prairie Island and Monticello, and we have made significant changes to our capital forecast relative to our 2015 resource plan. In our 2015 resource plan, we stated that our projected capital spend for Prairie Island was outpacing the estimates included in our 2012 Changed Circumstances filing. We specifically noted that our five-year capital expenditure forecast from 2016 through 2020 had increased by roughly $175 million above what was anticipated in 2012, and that our forecast for the 13-year period from 2021 through 2034 would likely need to increase by roughly $600 to $900 million. At

[3] These reductions in our nuclear production costs are directionally consistent with the nuclear industry as a whole, which has achieved a more modest average reduction of approximately $5/MWh since 2012.

the same time, we noted that our O&M costs were lower than previously modeled and that those decreases in O&M offset the increases in forecasted capital spend.

Today, we are in a position to materially reduce our capital forecasts. To date, we have spent $77 million less at Prairie Island than we anticipated in 2015. And relative to that 2015 Resource Plan budget, we now forecast spending approximately $475 million less in capital at our nuclear plants from 2019 through their current licenses relative to our 2015 forecast (approximately $245 million less at Prairie Island and about $230 million less at Monticello during this period, excluding incremental spend required for the ten-year extension).

The updates to our forecast reflect several years of work by numerous Company employees, leadership, and external consultants, as well as a recognition that we had to re-envision our approach to nuclear operations if our plants were going to remain competitive. The forecasts are based on a detailed, long-range capital budgeting process that was undertaken following our last Resource Plan. As part of this process, teams from nuclear engineering and capital projects assessed the condition of our plants and developed a long-range project forecast to support continued operations and aging management. These teams then worked with nuclear finance to develop budgets to support project needs, and probabilities were assigned to the various projects reflecting the likelihood each would be necessary to maintain the reliability of our plants. We then worked with independent consultants with expertise in nuclear operations to assess both our budgeting process and the overall level of our capital budgets, in order to ensure that our forecast were reasonable and aligned with industry norms.

We recognize that our stakeholders and the Commission will continue to monitor our performance and investments relative to our forecasts, and we anticipate an in-depth discussion regarding our Monticello forecasts in the context of a future certificate of need filing for additional dry cask storage. We anticipate filing that petition in the mid-2020s, at which point we will have an even longer track record of performance both in terms of capacity factors and spend. We look forward to demonstrating that our nuclear plants can continue to drive both environmental performance and benefits for our customers.

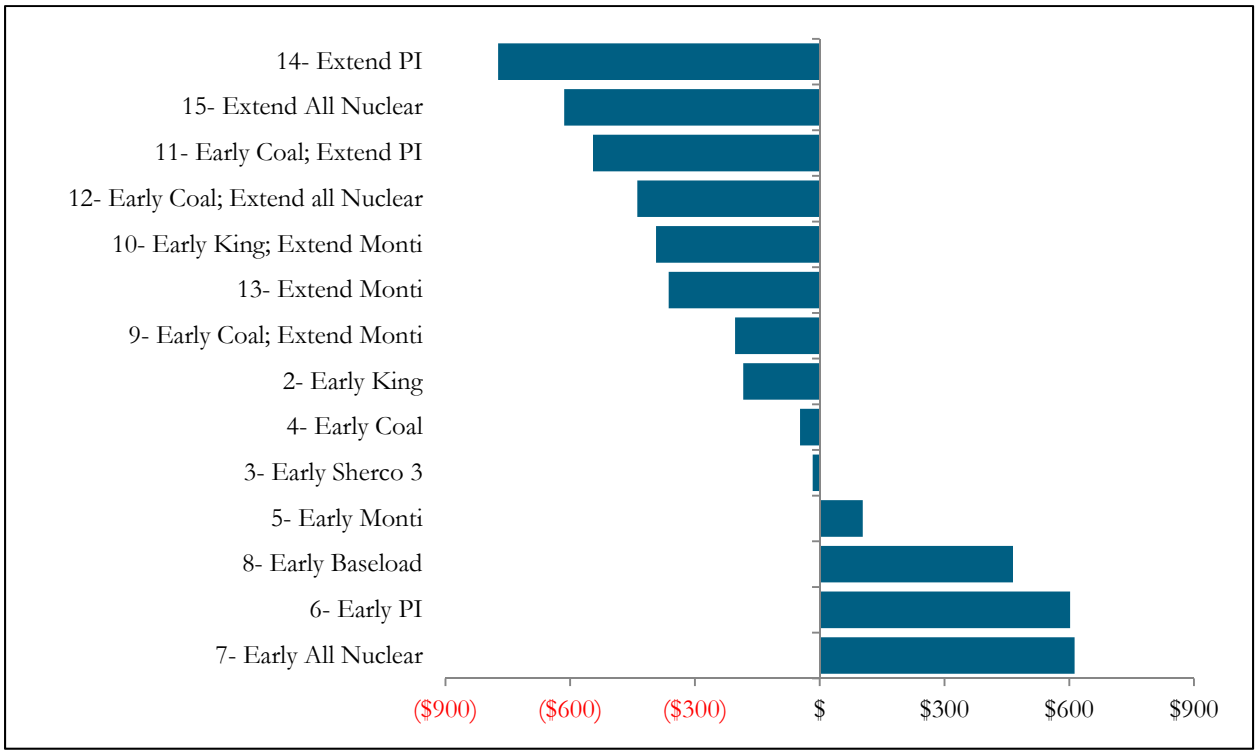
D. Benefits of Relicensing

Our Preferred Plan includes the operation of Prairie Island through its current licenses (expiring in 2033 and 2034) and a ten-year extension on the operation of Monticello (through 2040). The Strategist modeling of our plan demonstrates both that the continued operation of Prairie Island and the extension of Monticello are cost effective and expected to result in customer benefits. We discussed our Economic Modeling Framework in Chapter 5 but we briefly summarize the nuclear-specific results below.

As part of our economic analysis, we modeled scenarios that included early retirements, license extensions, and continued operation through current licenses for all three of our nuclear units. For the early retirement scenarios, we assumed a 2026 retirement date for Monticello and 2025-2026 retirement dates for Prairie Island Units 1 and 2, respectively. For license extensions, we limited our analysis to ten additional years of operations. While the NRC grants license extensions in 20-year increments, we believe it is prudent to limit our analysis to 10 additional years at this juncture, given the uncertainty of projecting more than 30 years into the future from both a budgeting and resource-planning perspective. Thus, the license extension dates are 2040 for Monticello, 2043 for Prairie Island Unit 1, and 2044 for Prairie Island Unit 2. We then combined these various scenarios with consideration of early coal retirements in order to develop a Preferred Plan.

In general, our analysis shows that extending operation of our nuclear plants is beneficial and least-cost when compared to other scenarios. The following table summarizes the Strategist results for each of the modeled scenarios:

Figure 1: Scenario PVRR Deltas from Reference Case ($2019 millions)



To be clear, our Preferred Plan is not the least cost scenario of the 15 options considered in terms of either PVSC or PVRR savings. The least-cost scenarios all include an extension of Prairie Island in addition to Monticello. But we believe the later retirement dates for Prairie Island—which are outside the planning period of the Resource Plan—give us additional time to consider this option before pursuing a license extension at Prairie Island.

Nevertheless, our Strategist modeling demonstrates that the extension of Monticello for an additional ten years is least cost and in our customers' interest. It also demonstrates that the continued operation of Prairie Island is superior to any of the early retirement scenarios. We believe these results provide strong support for our Preferred Plan and demonstrate the importance of our nuclear fleet from an overall resource planning perspective.

In addition to the economic benefits identified by Strategist, we believe it is also important to note the state, community, and employment benefits associated with our

nuclear fleet. Our plants employ approximately 1,400 staff in and around the Monticello and Red Wing communities, which translates into an estimated 4,200 additional jobs in other industries across Minnesota. The plants are also an important sources of tax base for their host communities, resulting in a combined total of approximately $42 million in state and local taxes annually. In total, Xcel Energy's nuclear operations contribute approximately $1 billion in annual economic benefits throughout the state. These and other benefits area summarized in NEI's April 2017 report titled "The Impact of Xcel Energy's Fleet on the Minnesota Economy," which looked at data from 2014-2016[4] and is included as Appendix O3.

In short, we believe our nuclear plants provide wide-ranging and substantial benefits not only to our customers but also the environment, the State of Minnesota, and the communities we serve. The continued operation of these plants, including a ten-year extension of operations at Monticello, is in the public interest, is consistent with state policy, and is necessary to achieve our carbon reduction goals at a reasonable cost.

E. Relicensing & Certificate of Need

Although 2030 is more than a decade away, the NRC relicensing process is a long-term project that must be commenced during the five-year action plan of this Resource Plan. In this section, we discuss the NRC process of relicensing Monticello for an additional 20 years, as well as the Certificate of Need filing we will make for additional dry fuel storage.

The Atomic Energy Act authorizes the NRC to issue licenses for commercial power reactors to operate for up to 40 years.[5] These licenses can then be renewed for additional 20-year periods of "extended operation" under the NRC's License renewal rule (10CFR Part 54). Both Monticello and Prairie Island successfully received NRC approval for initial license extensions and are currently operating under the extended licenses. Approximately 90 percent of plants in the United States have already

[4] The 1,400 staff and $42 million in state and local taxes referenced above reflects updated information as through 2018.

5 Economic and antitrust considerations, not limitations on nuclear technology, determined the original 40-year term for reactor licenses. However, because of this selected time period, some systems, structures, and components may have been engineered on the basis of an expected 40-year service life. As such, a renewed license requires "aging management programs," to monitor and manage the effects of continued operation on these equipment and structures.

renewed their licenses once, extending their operation to 60 years. Most of these plants will soon reach the end of their 60-year term, and many are in the process of considering a subsequent license renewal (SLR), which would extend a plant's operation from 60 to 80 years.

To obtain an SLR, a plant must provide the NRC with an assessment of the technical aspects around plant ageing and demonstrate that it can continue to operate safely.[6] This includes review of system metals, welds and piping, concrete, electrical cables, and reactor pressure vessels. The renewal process also includes an evaluation of potential environmental impacts associated with an additional 20 years of operation. The NRC verifies evaluations through inspections and audits, and its review of license renewals is expected to last anywhere between 22 and 30 months.

That said, there is no requirement that the NRC complete its review within this time frame. There is, however, a five-year safe-harbor provision that allows operators to ensure that a plant's license will not expire during the NRC review process.[7] Specifically, 10CFR2.109(b) provides that the existing license for a plant will not be deemed to have expired during the SLR review process, provided that the licensee filed its application at least five years before the expiration of the current license. Additionally, we note that the NRC is currently reviewing three plants that have already submitted SLRs as part of a pilot program that is intended to pave the way for efficient processing of relicensing applications in the 2020s. We expect that the three pilot plants will receive license extensions in early 2020.

We intend to comply with the five-year safe-harbor in order to ensure that Monticello can continue operating throughout the entirety of the SLR review process. And because the five-year clock does not begin to run until an application is deemed "sufficient," we intend to submit our SLR application an additional six months early so that any completeness issues can be resolved before the five-year mark. Based on our experience with the first extensions for Prairie Island and Monticello, we further anticipate that it will take approximately three years to prepare the license renewal

[6] Each reactor's original license is based on a specific set of requirements, depending primarily on design. This set of requirements is called the plant's "licensing basis." The licensing renewal process provides continued assurance that the current licensing basis will maintain an acceptable level of safety for the period of extended operations.

[7] Once a license expires, a nuclear plant cannot return to operation, so it is important to comply with the safe harbor in order to avoid license expiration during the pendency of an SLR application.

application itself. This means we need to begin the SLR application process in mid-2021, so that we can submit the application to the NRC in mid-2024 (five-and-a-half years before the current license expiration in 2030.

We recognize that the Commission's ultimate decision as to the extension of Monticello will occur in the context of a Certificate of Need for additional dry cask storage, and we anticipate filing that petition in the mid-2020s when we are farther along in the SLR submittal preparation for the NRC review. However, because our work to prepare the SLR application will occur between 2021 and 2024, we are requesting that the Commission approve this work as part to of our proposed five-year action plan. In total, we estimate that the application renewal process will cost approximately $40-50 million, and we have accounted for this cost in our Strategist modeling. We will justify the reasonableness and prudency of these costs in a future rate case.

Meanwhile, we will continue to lead the industry in exploring used fuel strategies, including consolidated interim storage and transportation issues that may facilitate additional used fuel management options not yet available in the industry. Just two months ago, Xcel Energy hosted an NEI nuclear transportation table top exercise that simulated shipping casks across the county to an interim storage site. This first-of-its-kind exercise involved the participation of several organizations—including the NRC, state commissions, host communities, tribal governments, and other utilities—all of whom will be important partners as we work on fuel management options. Thus, while we have the expertise and facility to safely store used fuel on site at our plants into the future, we will continue to lead the industry in exploring alternative transportation and storage opportunities.

F. Conclusion

This Resource Plan filing represents the first of many steps that will be required to obtain the necessary approvals to extend the Monticello operating license. This process will involve an extended dialogue with our stakeholders and regulators, both at the NRC and our state Commissions. We look forward to engaging with our stakeholders around the role of nuclear in our energy future.

Our specific request in this Resource Plan is to approve a five-year action plan that includes the preparation of an SLR license application, so that we can proceed on a timeline that allows for the potential relicensing of Monticello until 2040. If the Commission approves this plan, we will be back in the coming years to seek a Certificate of Need for additional dry fuel storage. At that time, we would expect to have a more in-depth discussion regarding the detailed capital and O&M forecasts, as well as the impacts of continued operations on the local communities, the state, and our customers.

APPENDIX L – XCEL ENERGY RESOURCES: SHERCO CC

I. INTRODUCTION

We are moving forward with project development for a Combined Cycle (CC) gas plant at the Sherco site that will replace part of the capacity retiring at current Sherco Units 1 and 2, as discussed in our previous resource plan. The Sherco CC will give us an important firm dispatchable resource necessary to successfully reduce our Upper Midwest NSP System carbon emissions by 80 percent from 2005 levels by 2030 and transition to 100 percent carbon-free in 2050 – while ensuring reliable and affordable electric service to support our economy and communities. This transition will put us in many untested circumstances, where it will be critical to have viable system options to provide flexibility to respond. No one yet knows what that future looks like – and we are confident that it relies on technologies that are not yet developed. It is prudent and responsible, and our obligation as a public utility, to ensure we are planning and implementing viable infrastructure options that will help to drive a successful and economic transition to a stable future state.

Our previous Resource Plan stated that, in order to retire the coal-fired units, there were certain grid reliability issues that would need to be resolved, as well as community support objectives to meet. Those issues remain true today. There have also been several developments since our last Resource Plan that reinforce and highlight the system benefits the Sherco CC will provide.

Overall, building a new CC at the Sherco site is the most appropriate holistic solution to serve grid needs when the Sherco coal units retire, for the following reasons:

- It will provide system needs including voltage support, power deliverability, and system regulation in the absence of Sherco Units 1 and 2.
- It will provide replacement capacity for our black start restoration path.
- It will facilitate our carbon reduction plan in three ways. First, in providing the grid support the Monticello nuclear plant needs (and which will be absent if the Sherco Units are not replaced). Second, by facilitating the integration of large renewable additions contemplated by our Preferred Plan. Third, by avoiding the costly and lengthy transmission upgrades that would be required if we built new units on a greenfield site.
- It will satisfy, in part, the system's need for sufficient firm and dispatchable capacity as our coal units retire and do so in a way that is superior to CTs

because of the lower heat rate and emission profile.

- It will help us fulfill our commitments to the Becker community as we transition away from legacy coal-fired baseload assets.

We discuss each of these factors in more detail below, and we also provide an update as to the status of the Sherco CC project.

II. THE NEED FOR THE SHERCO CC AS DISCUSSED IN OUR LAST RESOURCE PLAN

In our last Resource Plan, we proposed to retire Sherco Units 1 and 2, which provide approximately 1,400 MW of stable, baseload generating capacity to our system. Given the amount of energy and firm capacity these two baseload units provide, we undertook an in-depth analysis to determine the grid needs that would arise upon their retirement.

The specific studies the Company undertook included an Attachment Y2 study, performed by MISO, and a separate study by Siemens Power Technologies International. The Y2 is a non-binding, informational study that identifies any reliability impacts of a potential future status change of a generating unit(s) – in this case, Sherco Units 1 and 2. The MISO Tariff requires that any generation retirement be studied and approved by MISO to ensure that it results in no adverse effects to the reliability of the system, and we commenced the Y2 study when we first contemplated retiring Sherco Units 1 and 2. The focus of this study was on the impacts to the broader MISO grid if one or both of Sherco Units 1 and 2 ceased operation.

We retained Siemens to study the effects of potential phased retirement of one or both Sherco Units on the transmission system, technical implications (including voltage analyses and transient stability analyses) and upgrade costs associated with replacement of one or both Units at alternate locations on the NSP System, and the potential impacts of the cumulative effect of additional larger generation unit retirements on the NSP System, in particular the Monticello Nuclear Plant due to its proximate location in Sherburne County and one Prairie Island Unit in combination with Sherco Units 1 and 2.

Below we briefly discuss the studies' findings and note that each of the issues identified by the retirement of the Sherco Units below is solved by the Sherco CC – holistically and at a prudent cost to our customers. For a more in-depth discussion of these reports, please see Attachment D to the Company's January 29, 2016

Supplement to its 2015 Integrated Resource Plan in Docket No. E002/RP-15-21.

A. Voltage Support

The Y2 study found that retiring the existing units (with no replacement solution) would result in significant violations of the prevailing voltage and thermal ranges. Analysis of bulk electric system (BES) impacts from new or changing generation and transmission facilities are measured against standards and requirements established and enforced by the North American Reliability Corporation (NERC), per authority from FERC.[1]

The real-time conditions on the transmission system are constantly changing and require ongoing adjustments to maintain voltages at required levels. As large synchronous power sources, Sherco Units 1 and 2 also provide system voltage support and reactive power. The system must be able to facilitate both "active" and "reactive" power. Active power, measured in watts, is the form of electricity that powers equipment. Reactive power, measured in volt-amperes reactive (VARs), is the energy supplied to create or be stored in electric or magnetic fields in and around electrical equipment. Reactive power is particularly important for equipment that relies on magnetic fields for the production of induced electric currents (e.g., motors, transformers, pumps and air conditioning). Due to physics, reactive power can be transmitted only over relatively short distances, and thus must be supplied as needed from nearby generators. If the correct level of reactive power cannot be supplied promptly and in sufficient quantity, voltages deteriorate and, in extreme cases, can result in a voltage collapse.

The issues identified by the Y2 study were significant enough that MISO would likely designate the units as System Support Resources (SSR) and not allow them to retire as planned, if an alternate mitigation was not in place. These violations would also be in conflict with the Monticello nuclear plant's operating license. To move forward with the Sherco retirements, MISO and/or the Nuclear Regulatory Commission (NRC) would require that the Company mitigate the identified voltage and thermal violations in another manner, generally requiring either new firm generation on site or significant transmission system upgrades.

B. Power Deliverability

The Siemens' analysis confirmed that the system operates well with significant

[1] We discuss NERC's role in more detail in Appendix J1: Baseload Study.

injection at the Sherco site and that replacing the retiring units at a different location would require transmission system upgrades and come with other tradeoffs (i.e. increased energy losses from a new unit placed further away from the Twin Cities' load center). Transmission systems are typically developed to receive significant amounts of power from specific injection sites and then move the power over long distances to meet areas of demand. This amount of power than can be moved is often referred to as "transfer capability," and changing generator characteristics or locations impacts the performance of the surrounding grid by impacting Transfer Capability.

Our system was designed to receive significant injections of power from the Sherco site and then deliver energy out from it to areas of customer demand, including the Twin Cities metro area. The Siemens study confirmed that replacement of Sherco Units 1 and 2 with a large generating unit that provides similar benefits to the NSP System as the existing Sherco Units (like a combined cycle) will cost-effectively meet the physical system requirement to ensure voltage, frequency, and reliable service for our customers.

C. System Regulation

The Siemen's analysis also addresses the heavy reliance of the system on Sherco Units 1 and 2 for system regulation. System regulation essentially refers to the ability of the system to maintain reliable operation through changes in usage and production. In other words, equipment that provides system regulation ensures that the grid is keeping generation and load in balance at all times.

To maintain this balance, there is a need for system resources that are flexible and responsive to dispatch signals. Currently, the system relies heavily upon units like Sherco Units 1 and 2 to provide this type of regulation. The overall system frequency, required to be maintained at 60 Hz in the U.S., is an active measure of this balance. When there are sudden large changes to the generation and load balance, such as a generating unit dropping offline or an event that disrupts operation of a transmission facility, the frequency of the grid can fluctuate up and down depending on the size of the disturbance. The grid requires sufficient system regulation, which means its ability to respond instantly to changes in usage – i.e., keeping the generator and loads matched at all times. Insufficient system regulation can cause disturbances like these to make the system unstable. However, the Sherco CC addresses these system regulation issues because of its electrical characteristics that provide this fast response balancing in real time, similar to Sherco Units 1 and 2 today.

D. Black Start

In addition to the needs identified by the studies discussed above, Sherco Units 1 and 2 also play a critical role in our system when it comes to black start planning. In the event of a major outage, the existing Sherco Units 1 and 2 units are an integral "Target Unit" in our grid restoration plan. Once an "Initial Unit" (i.e. the unit that jumpstarts the grid) is re-started, Sherco Units 1 and 2 can be started and run at low loads and provide the necessary capabilities to restart other key generators, such as Sherco Unit 3, in the restoration path.

Only dispatchable units of a certain size that are capable of creating and absorbing reactive power are eligible to provide this function, and there are few viable alternatives in our current system. Nuclear units, for example, can only come online after the system is fully stable, and thus are not used as Target Units. Renewable generation, such as solar and wind, are generally not able to provide these services effectively, nor for the duration needed to serve as the Target Unit, due to their inability to create and absorb sufficient levels of reactive power – and because they are weather-dependent and not firm and dispatchable. A large battery energy storage system can technically be configured to be capable of providing black start service, likely as part of a relatively small initial black start unit. However, current battery technologies may not yet be economically viable for this purpose. There are also technical concerns with regard to how batteries can absorb reactive power, which would be needed if the battery was not paired with another type of generation asset.

While the Blackstart Plan can be re-routed if needed, constructing the proposed CC at Sherco provides the most efficient restoration path, and avoids other upgrades that would be required to re-route the path. As we noted in our January 29, 2016 Resource Plan Supplement in Docket No. E002/RP-15-21, altering the path away from the Sherco site would require various equipment upgrades on our transmission system and potentially the addition of new generation elsewhere if transmission upgrades could not fully mitigate this need. Selecting a less efficient path would also lengthen the overall restoration period, which may result in other restoration challenges during cold weather events.

III. EMERGENT ISSUES IN THIS RESOURCE PLAN

Since the last Resource Plan, the system conditions discussed above and underlying our need for a new CC at Sherco have not changed in any material way. In fact, we see many of the reliability issues identified becoming more relevant and pronounced in light of our aggressive carbon goals and the transmission interconnection

constraints that have emerged in recent years. Below, we discuss the issues new to this Resource Plan, which we believe further confirm the need for the Sherco CC.

A. Monticello Extension

Extending the Monticello nuclear plant's operational life for 10 years past its current retirement date helps us retain zero emissions baseload power on the system while we integrate additional intermittent renewables (in particular, solar PV) in 2025 and beyond. However, as discussed in our last Resource Plan, we need a large grid-stabilizing resource to ensure we can operate Monticello within the requirements of our NRC operating license. And the transmission issues outlined in our previous Resource Plan filing have also not improved. In fact, the MISO generator interconnection queue is more congested now than it was in 2016, with substantial new renewable generation proposed but very little additional transmission capacity dedicated to integrating those resources. This would very likely impact our ability to site necessary stabilizing resources in a greenfield location near Monticello, and any new unit would likely be responsible for substantial transmission upgrade costs to interconnect to the broader grid—assuming it could even make it through the MISO queue in time to facilitate a 2026 retirement of Sherco Unit 1.

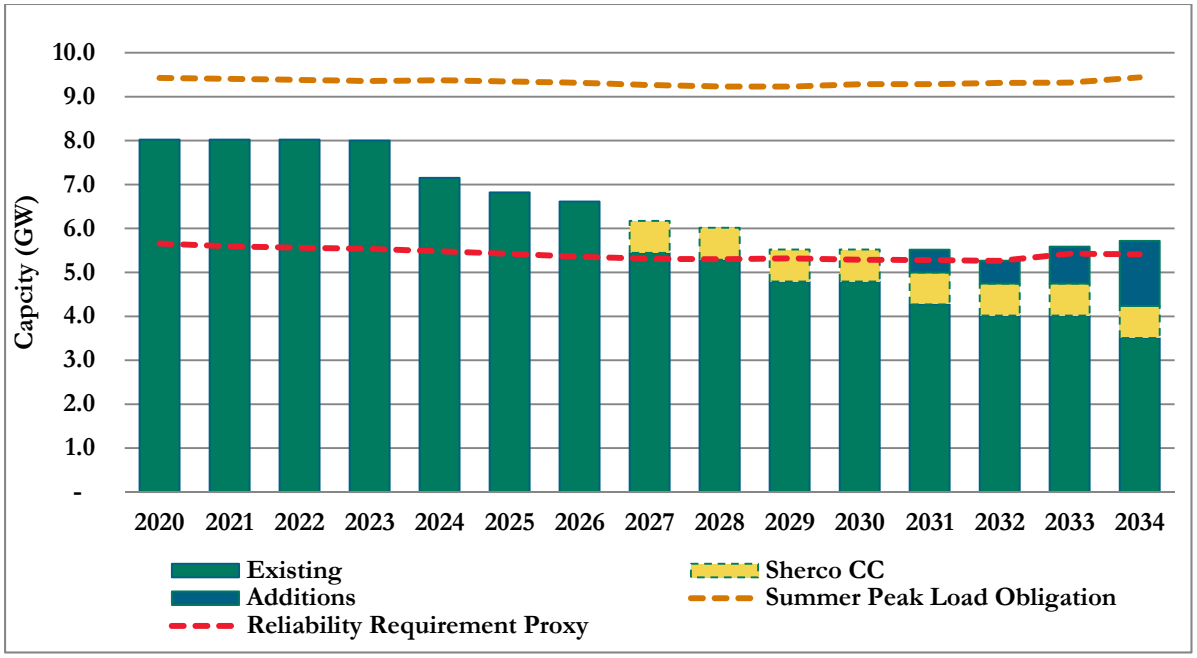
B. Reliability Requirement

Not only is the Sherco CC beneficial in supporting the proposed Monticello extension, it also helps ensure that we have sufficient load supporting, firm dispatchable resources on our system for grid resilience and reliability purposes. As we increase the amount of renewable generation on our system, these resources alone cannot reliably provide customers the energy they demand every hour of every day – or maintain the stability of the grid. Until MISO planning constructs fully incorporate measures to address the emerging challenges associated with increasing levels of renewables, we have incorporated a Reliability Requirement into our planning for this Resource Plan (See Appendix J2). Our Preferred Plan does not show a need for additional load supporting resources until 2031, which is partially so because the Sherco CC is already modeled as a part of our future resource portfolio.

As seen in Figure 1 below, if we were to forego building the Sherco CC, we would begin to see a firm capacity deficit relative to the Reliability Requirement by 2029, with the gap widening post-2030 when Sherco Unit 3 retires. Given technologies available today, this need would be most cost-effectively be filled by gas combustion turbines (CT). However, CTs also typically run at higher heat rates, with higher levels of emissions than CCs. While we have said we can wait until future cycles to

reevaluate and determine which technologies may be able to meet these needs in the post-2030 timeframe, we have a responsibility to ensure we meet our customers' needs now. The confluence of Monticello and grid stability needs, and proposed coal retirements further support that the Sherco CC is an appropriate choice to provide that system reliability service in the near term.

Figure 1: Projected Firm Capacity as Compared To Summer Peak and Reliability Requirement[2]



We are facing a long transition from today to 2030 – and even longer to 2050 – with significant changes at multiple stages. We must have operation options that give us flexibility to respond to many unknowns that are sure to come. The Sherco CC will help us make this transition responsibly, while we monitor developments and take advantage of technologies, such as hydrogen and other carbon-free fuels when they become commercially-viable. We discuss some of these resources in Appendix F6: Resource Options.

C. Renewable Integration Support

As we begin to integrate even higher levels of variable renewables on our grid, the

[2] Note that our Preferred Plan modeling also includes MEC's full capacity throughout the planning period, which may result in an additional gap if the proposed acquisition is not approved. The firm supply depicted here also includes DR additions per the Preferred Plan.

value of a dispatchable intermediate resource like the Sherco CC increases. Our Preferred Plan includes 4,000 MW of new renewable development, some of which would be added as early as 2025. Adding substantial new variable renewable resources requires us to maintain a subset of resources that can provide both fast ramping capabilities and the longer duration energy needs, for times when these variable renewables are not available. Moreover, these renewable additions will occur during the same period in which we are retiring over 2,400 MWs of coal-fired generation (1,360 MW of previously planned coal retirements from Sherco Units 1 and 2, and another 1,045 MW of retirements by 2030 proposed at Sherco Unit 3 and King. As we replace increasing amounts of existing coal generation with cleaner fuels, the Sherco CC will support our transition by allowing us to reduce and ultimately eliminate dependence on coal units for these balancing and integration needs going forward.

Additionally, as the MISO region realizes substantially higher levels of renewables, planning constructs need to change from today's single system peak capacity construct – and adapt to the diminishing marginal returns these variable resources can provide. MISO has itself acknowledged in its *Renewable Integration Impact Assessment* (RIIA) study that, at higher levels of renewable adoption on the grid, the ELCC of wind and solar resources will decline.[3] The firm capacity the Sherco CC will provide will become even more valuable in meeting our customers' needs every hour of every day as we navigate this transition while maintaining reliability.

D. Community Impact

Aside from significant grid support benefits discussed above, the Sherco CC also will partially offset the community tax and employment losses in Becker and Sherburne County that will result from the early retirement of the existing Sherco Units (including our proposal in this Resource Plan to retire Sherco Unit 3 in 2030). It also provides options for continued industrial steam supply to the Liberty Paper recycling facility located nearby. In addition, the Sherco CC could also provide options for our Sherco Unit 3 partner, Southern Minnesota Municipal Power Agency (SMMPA). These host communities and partners have been an integral part of our system for nearly 45 years, and we are committed to partnering with them as part of our upcoming baseload transition in hopes of mitigating the impacts of our Sherco retirements. Building a new CC unit at Sherco offers us the opportunity to meet our grid needs and serve the public interest, while also mitigating the impacts to these host communities and partners.

[3] *See* Chapter 2: Planning Landscape and Appendix J1: Baseload Study for more detail.

IV. ALTERNATIVE OPTIONS

While it is possible to meet some of the identified grid needs with alternate investments, the Sherco CC provides a path to meet all of these needs holistically and at a prudent cost to our customers. Below we discuss the three alternatives we evaluated: (1) a Synchronous Condenser (SC), (2) renewables-plus-storage, and (3) alternative greenfield CC solutions. We discuss each of these alternative options briefly below and will expand this discussion in detail in our upcoming Sherco CC regulatory filing.

A. Synchronous Condenser

With respect to voltage support, one potential alternative solution would be the conversion of one existing generating unit into a Synchronous Condenser (SC). A SC is a motor, whose shaft is not connected to anything but spins freely. Its purpose is not to produce electric power, but to adjust conditions on the electric power transmission grid. Our initial analysis indicated that a SC may provide the required continuous voltage support the Monticello plant requires as well as the requisite inertia (due to its large rotating mass) to meet the grid's stability needs. However, a SC would not be able to address the thermal support Monticello requires or the black start capabilities the system requires.

In addition, our Preferred Plan proposes to retire Sherco Unit 3 in 2030. This has two key implications for the viability of a SC as an alternate investment to the planned Sherco CC. First, our Preferred Plan includes a proposal to pursue a Monticello nuclear operating license extension that would allow us to operate that plant through 2040. Both the Monticello license extension and our proposal to retire Sherco Unit 3 in 2030 are fundamental components of our carbon reduction goals. The SC design we studied, however, would not be able to provide the grid services we need to remain compliant with our nuclear operating license after Sherco Unit 3 retires. Indeed, it is not clear that the NRC would approve a relicense with only SC support, as opposed to a generating facility. And even if it were approved with only SC support, the SC would need to be much larger than previously anticipated in order to provide similar grid stability benefits after all the 2,400 MW of existing Sherco generation retire. Further, a SC provides reactive power by consuming power. Because of this, a SC does not address the need for firm dispatchable resources to meet our customer's capacity and energy needs. In this way, the Sherco CC provides a much greater value to the overall system.

Second, the three existing Sherco Units are key components of our current Black Start Plan, and a SC on its own cannot replace this functionality. We noted in our last Resource Plan that our Black Start Plan is substantially dependent on capacity at Sherco Units 1 and 2 being Target Units, and providing sufficient output to support restarting Sherco Unit 3 and then the remainder of the NSP system. Retiring Sherco Units 1 and 2 would require re-designing our restoration path and potentially substantial associated transmission upgrades, if not replaced with another type of firm and dispatchable generation. The Sherco CC helps us to bridge that gap after Sherco Unit 1 retires in 2026. Now that we are also planning to retire Sherco Unit 3, the Sherco CC becomes even more essential in maintaining our black start capabilities. Because the SC does not generate real power, it cannot provide the Black Start functionality that we need for our system.

B. Renewables Plus Storage

Given the Company's clean energy goals, we also considered whether or not a paired renewables-plus-storage facility could provide a viable alternative solution to the Sherco CC. While the renewable plus storage might provide adequate capacity and energy, a SC may also be needed to meet the grid reactive power voltage support needs discussed earlier. We anticipate storage being a key part of our system in the longer term, however, such a solution is not currently cost-effective at the scale required for this application – and would be much more complex to implement and operate. It is also not clear whether the NRC would allow a storage facility to serve as the external support required by our nuclear operating license for Monticello. Even assuming it was approved, though, the external support unit is required to be available for a duration exceeding the longest potential outage that Monticello could encounter. In normal operational conditions, outages for refueling at the plant could be expected to last approximately 30 days. This duration is far longer than currently available storage solutions could be reasonably expected to provide support, much less provide it at a reasonable cost. Even a solution that could, for example, provide continuous grid support of this magnitude for a single 24-hour period would be exorbitantly expensive.

In this example, such a plant would require a battery configuration that could provide hundreds of MW of full discharge capabilities for multiple cycles. And while we expect the cost and capabilities of battery technology to improve over the planning period, it is highly unlikely they would improve sufficiently to make this a more cost effective solution than the Sherco CC. The Sherco CC will be able to provide continuous support to the broader grid and Monticello across many consecutive days – indeed months - without needing to pull significant energy from another on-site

generator, or the broader grid. Today's short-term energy storage solutions simply cannot provide this level or kind of support. Future technologies may make this type of solution much more viable and economic. However, with grid stability and reliability at stake, we do not see a renewables-plus-storage solution as a viable alternative to the Sherco CC at this time.

C. Alternative Greenfield CC

As discussed in more detail in Appendix I: Supporting Infrastructure-Transmission and Distribution, the existing transmission system's capability to interconnect new projects without substantial infrastructure upgrades is very limited, and thus, the generation interconnection planning studies indicate there will likely be costly upgrades assigned to the prospective generators. The value of our Sherco interconnection is incredibly valuable due to the potential for upgrade costs assigned to greenfield projects as well as the time component associated with the interconnection process.

In 2018, we asked an independent engineering consultant to help us evaluate the cost and feasibility of building a greenfield CC plant. Six potential sites were examined. Overall, the study led us to the conclusion that building a greenfield CC would not be an economically favorable alternative, nor would a plant likely be able to be placed in-service in the timeframe we needed. As greenfield sites, we would have to gain new interconnection rights and conduct transmission system upgrades that would present significant challenges not only to building a cost competitive solution to the Sherco CC, but also to achieving the 2026 in-service date we need to transition Sherco Unit 1 off the system. The study determined that, across these six potential locations, the average required transmission system upgrade costs for a selected site would amount to more than $500 million.

To put the plant in service by the time Sherco Unit 1 retires, the study determined we would need to see a 60 percent withdrawal rate from the MISO interconnection queue as it existed at the time of evaluation.[4] In our experience, it would be unrealistic to expect transmission upgrades, and any necessary transmission and plant permitting and interconnection processes, to be completed in an appropriate timeframe for a greenfield site option to be viable. Thus, this was determined to not be a favorable alternative to the Sherco CC.

[4] The Interconnection Cost Estimate Study performed by Excel Engineering is provided in this filing as Appendix R.

V. CURRENT STATUS

The Company is currently in the project development stage with regard to moving forward on the Sherco CC. We expect this plant to utilize the best available technology for the design specifications at the time of construction, based on technology information from the major equipment suppliers in the market. When it is built and put into service, we also expect the plant to be the most efficient gas generator, with the lowest carbon emission rates, in our generation fleet and that it will be competitive in the MISO Upper Midwest market as well.

The project specifications are based on a 2x1, wet-cooled, unfired design condition. We have used internal estimates and currently available technology information to include the plant, and estimated associated new infrastructure required, in the Strategist-modeled portfolios presented in this Resource Plan. However, these cost estimates are preliminary and subject to updates as we progress through the project development process. In preparation to move forward with the project, we are currently working with consultant engineering firms to develop more targeted and up-to-date cost estimates for the new generation facility and required firm natural gas supply infrastructure, and to better define expected project schedules. We expect these inputs to inform our project development plans moving forward, as we thoroughly evaluate equipment and infrastructure supply options and make any relevant filings to the Commission.

We also note that there are several steps we are preparing to complete with regard to generator interconnection rights for the Sherco CC, and this process will also affect how the Sherco CC development process moves forward. We expect we will need to file a MISO Attachment X generator interconnection request in order for the CC to utilize the same interconnection rights currently assigned to the Sherco coal units. This must be filed at least one year prior to the existing unit ceasing operation, and the new unit must go into service not more than three years after the existing unit(s) cease to operate. We plan to meet these requirements so that we can avoid the lengthy interconnection queue process.

When we file these details with MISO, that initiates any reliability studies required under the MISO Tariff – the results of which MISO will share within 180 days of the request.[5] The Tariff currently provides that these studies will evaluate whether the

[5] The Attachment X Tariff provides that the Transmission Owner [MISO] shall use Reasonable Efforts to complete the Replacement Impact Study and Reliability Assessment Study and share results with the Interconnection Customer within one hundred eighty (180) Calendar Days of the request.

replacement generating facility has a material adverse impact on the transmission system when compared to the existing generating facility and the performance of the transmission system, and to determine if thermal and/or voltage violations of applicable NERC standards and MISO planning criteria are caused by removing the existing generating facility from service prior to the commercial operation date of the replacement generating facility. Upon completion of these studies, Xcel Energy Transmission will subsequently study any required facilities upgrades or changes – and MISO will incorporate these into the new Generator Interconnection Agreement we receive for the Sherco CC.[6]

VI. CONCLUSION

The need to build new firm capacity at the Sherco site has not abated since our last resource planning cycle. The Sherco CC is an important bridge to the future. No one yet knows what that future looks like – and we are confident that it relies on technologies that are not yet developed. The Sherco CC will give us the necessary flexibility that help us through all the different transitional stages to come, without risking grid resilience and customer reliability. Without the Sherco CC, we will be challenged to maintain the clean baseload power provided by our Monticello unit into the future, and challenged to integrate the thousands of megawatts of new solar power proposed in our Preferred Plan, while retiring the last of our coal units.

For these reasons, we included the Sherco CC as a baseline resource in our Preferred Plan and in the additional scenarios we analyzed. We are moving forward with project development internally, including working with engineering consultants to develop more detailed estimates for the cost to build the CC and secure the associated firm gas supply for the site. These estimates will be used to help ensure the project is completed at a reasonable cost to our customers. We plan to bring forward a detailed filing to the Commission in the coming years, which will present the most up-to-date information for this project.[7]

[6] The evaluation currently consists of two studies: i) a Replacement Impact Study as set forth in Section 3.7.2.1 of the GIP, and ii) a Reliability Assessment Study as set forth in Section 3.7.2.2 of the GIP.

REPORT

Forward-looking Statements

Except for the historical statements contained in this report, the matters discussed herein are forward-looking statements that are subject to certain risks, uncertainties and assumptions. Such forward-looking statements, including the 2019 EPS guidance, long-term EPS and dividend growth rate, as well as assumptions and other statements are intended to be identified in this document by the words "anticipate," "believe," "could," "estimate," "expect," "intend," "may," "objective," "outlook," "plan," "project," "possible," "potential," "should," "will," "would" and similar expressions. Actual results may vary materially. Forward looking statements speak only as of the date they are made, and we expressly disclaim any obligation to update any forward-looking information. The following factors, in addition to those discussed elsewhere in this Annual Report on Form 10-K for the fiscal year ended Dec. 31, 2018 (including the items described under Factors Affecting Results of Operations; and the other risk factors listed from time to time by Xcel Energy Inc. in reports filed with the SEC, including "Risk Factors" in Item 1A of this Annual Report on Form 10-K hereto), could cause actual results to differ materially from management expectations as suggested by such forward-looking information: changes in environmental laws and regulations; climate change and other weather, natural disaster and resource depletion, including compliance with any accompanying legislative and regulatory changes; ability of subsidiaries to recover costs from customers; reductions in our credit ratings and the cost of maintaining certain contractual relationships; general economic conditions, including inflation rates, monetary fluctuations and their impact on capital expenditures and the ability of Xcel Energy Inc. and its subsidiaries to obtain financing on favorable terms; availability or cost of capital; our customers' and counterparties' ability to pay their debts to us; assumptions and costs relating to funding our employee benefit plans and health care benefits; our subsidiaries' ability to make dividend payments; tax laws; operational safety, including our nuclear generation facilities; successful long-term operational planning; commodity risks associated with energy markets and production; rising energy prices; costs of potential regulatory penalties; effects of geopolitical events, including war and acts of terrorism; cyber security threats and data security breaches; fuel costs; and employee work force and third party contractor factors.

Who we are

Every day we power millions of homes and businesses across eight Western and Midwestern states. Our customers can count on us to be there 24/7 with safe, reliable energy. But, what we provide goes much deeper than that.

Based in Minneapolis, we are a recognized industry leader in delivering renewable energy and in reducing carbon and other emissions, efforts that have put us on a path to a more sustainable energy future. Through a growing range of innovative solutions, we continue to empower customers with energy options and alternatives to support their goals and objectives.

Destination 2050 is all about delivering on our bold vision for a carbon-free future. We are the first major U.S. energy provider to announce an aspiration to serve customers with 100% carbon-free electricity by 2050.

In a rapidly changing industry, we are taking a smart and thoughtful approach to how we produce and deliver energy, looking for better ways to serve our customers and anticipate their needs and expectations. Through our efforts, we are not just preparing for the future we are building it, today.

Our Vision

We will be the preferred and trusted provider of the energy our customers need.

Our Mission

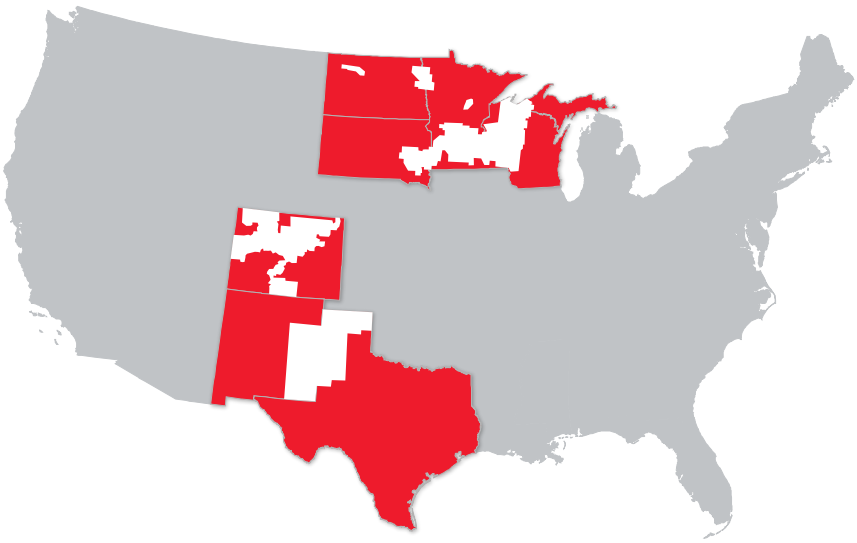
We provide our customers the safe, clean, reliable energy services they want and value at a competitive price.

Our Values

Our values reflect our core beliefs — who we are, how we conduct our business and the importance of our customers. They guide us in our work and in our interactions with each other. We are Committed, Connected, Safe and Trustworthy.

Our Service

Xcel Energy is a major U.S. regulated electric and natural gas delivery company with four utility subsidiaries. We serve 3.6 million electric and 2 million natural gas customers across parts of Minnesota, North Dakota and South Dakota (Northern States Power Company-Minnesota); Wisconsin and Michigan (Northern States Power Company-Wisconsin), Colorado (Public Service Company of Colorado); and Texas and New Mexico (Southwestern Public Service Company).



Message from the CEO

To Our Stakeholders:

For decades, the fundamental role of energy providers was simple: keep the lights on. But as energy has become more central to people's lives, expectations are far greater. Today our customers and communities depend on us to do much more — especially when it comes to leading the transition to clean energy and confronting the risk of climate change.

At the end of 2018, we became the first energy provider in the country to announce plans to serve customers with 100% carbon-free electricity by 2050. The theme of this report — Destination 2050: Building the Future — describes our bold vision for a carbon-free future while delivering the reliability and affordability that our customers need and expect.

A Carbon-free Energy Future

Clean energy matters to our stakeholders. It matters to us too. We've been at the forefront of the clean energy transition for the last 15 years. Since 2005, we've reduced carbon emissions by 38%, and the confluence of changing customer preferences, declining prices of clean technologies and the latest climate reports have accelerated our plans.

On our way to Destination 2050, we established a new interim goal to reduce carbon emissions produced from the electricity that serves our customers by 80% in 2030. We believe we can reach this 2030 target by using existing technologies. Removing the last 20% of carbon from the grid will require advances in technology to develop carbon-free, always-on energy sources. But I'm optimistic and believe we can get there.

To reduce carbon as quickly as possible without impacting reliability and affordability, we expect to continue our Steel for Fuel strategy of building large-scale renewables that deliver both economic and environmental benefits. We currently have a dozen wind farms under development with more on the drawing board. We also expect to expand our use of large-scale solar farms that provide the best consumer value. By 2030, we project renewable sources will generate at least 60% of our electricity. In addition to these renewables that serve all customers, we support customers who want more now by providing options to subscribe for up to 100% renewable energy through unique programs like Renewable*Connect in Colorado, Minnesota and Wisconsin.

Meanwhile, we have plans to retire four coal units in the early to mid-2020s — two in Minnesota and two in Colorado. Altogether, we are retiring half of our coal-fueled generation by 2026 — and are evaluating the feasibility of additional early retirements. As our energy mix changes with more renewables and less coal, we will continue to use more carbon-friendly natural gas as a bridge that supplies the back-up capacity to help integrate more renewables. We also plan to operate our carbon-free nuclear plants through their licensing periods in the early 2030s.

The easiest way to reduce carbon is to never produce it in the first place. We offer more than 150 energy efficiency programs to help our customers reduce their bills. In fact, five of those programs recently were acknowledged among the best in the country by the American Council for an Energy-Efficient Economy.

Companies like Xcel Energy are uniquely positioned to leverage our carbon-reducing expertise to other sectors of the economy. We're focusing our initial efforts on transportation, as we have several pilot projects under way to help make it easier for customers to purchase electric vehicles and produce 70% less carbon than gas-powered vehicles — and the results will get even better as we continue to transition away from fossil fuels. We have announced a $25 million investment in Minnesota to develop infrastructure needed to improve home charging and public charging capabilities and plan to expand these efforts soon to other states.

Building Stronger Communities

Just as EVs are beginning to gain traction, coal units are heading in the opposite direction. However, decisions to shut down a coal plant have significant ramifications to the employees who work there, along with the communities that benefit from the tax base.

Announcing plans years in advance is crucial to give these important stakeholders enough time to prepare for the change and provide economic development assistance where possible. A great example comes from Becker, Minnesota, where we announced the closure of two units at the Sherco Generating Plant. We have worked behind the scenes to provide economic development assistance to the local community through the construction of a natural gas-powered plant onsite, which will make up for lost generation, and to attract businesses. This includes Northern Metals Recycling, which is relocating from Minneapolis to Becker, and a large Google data center, pending approval.

As a local business, we're mindful of local spending that helps drive local economies. Last year nearly 70% of our purchasing was with businesses located in our service territory and 12% of our purchasing was with businesses owned by women, minorities or veterans. In addition, some of the projects we invest in, such as transmission lines and wind farms, create hundreds of local construction jobs and significant tax base.

Of course, we are also building the future by working with communities to help them reach their clean energy goals. We have partnered with several communities through our Energy Future Collaborations and Partners in Energy programs to help them reach their clean energy and sustainability goals.

This is in addition to providing reliable and affordable energy that our customers expect. These, along with a strong commitment to public safety, are table stakes in our industry. Last year, we delivered electric reliability that remains in the industry's top one-third, kept bills under the level of inflation and delivered our best-ever performance in gas emergency response. Another way we positively impact our communities is through our dollars and time. In 2018, the Xcel Energy Foundation and our employees donated more than $11 million and volunteered 90,000 hours with a focus on STEM education, economic sustainability, environmental stewardship and access to arts and culture.

Building our Future Workforce

To best serve our customers and solve tomorrow's energy challenges, we continue to build and train our workforce for the future. We are one team comprised of 11,000 employees. We recently refreshed our corporate values to better align with how we approach our jobs each day. Through a bottom-up approach, employees embraced our four values — Safe, Committed, Connected and Trustworthy — and demonstrate them each day when they come into work.

Through our performance management, professional development and recognition programs, we align employee responsibilities with our three strategic priorities: Leading the Clean Energy Transition, Enhancing the Customer Experience and Keeping Bills Low.

Employee safety is a core value for our organization and is at the forefront of everything we do. Although we achieved first-quartile employee safety in 2018, we had a few significant injuries. As a result, we re-doubled our safety precautions and expanded our communications efforts.

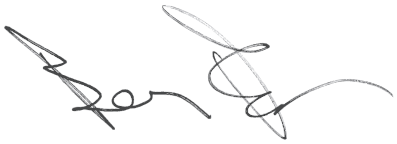
We are committed to hiring and retaining a diverse workforce. Thirty-four percent of our new hires were female, which is just slightly below first-quartile performance. Our hiring of people of color slightly increased to 24%, but remains short of our goals. We began developing customized diversity plans in five business areas, and we expect to build on that program in 2019. We also set a record with 66 high school interns and were named Employer of the Year by St. Paul-based Right Track, a youth training program.

Building the Future

Powering homes and businesses, driving economic development, supporting our communities and protecting the environment are fundamental to how we do business. We embrace the trust our customers place in us and our responsibility to deliver solutions to improve their lives. As you read our Corporate Responsibility Report, you will learn more about our progress and plans for building the future and fulfilling our economic, environmental and community responsibilities.

Thanks for your partnership on this important journey.

Sincerely,



Ben Fowke
Chairman, President and CEO

Corporate Responsibility Governance

How we define, govern and align corporate responsibility with our strategic priorities

For more than a century, Xcel Energy has had the privilege of serving customers and operating in hundreds of communities across its eight-state service territory. We have accomplished this by never losing sight of our responsibilities and the understanding that our success is uniquely tied to the success of those we serve.

Building the Future, Today

Our corporate vision is to be the preferred and trusted provider of the energy our customers need. To fulfill this, we view our success today and in the future not simply as a measure of profit but equally as our broader impact on the public good. We have a tremendous obligation and opportunity to power people's lives and possibilities with energy that they can trust to be safe, affordable and progressively clean. We work every day to deliver on these requirements for customers and other stakeholders through our focus on the following environmental, social and governance responsibilities.

Environmental Responsibility

Managing natural resources and protecting the environment

We are committed to minimizing and carefully managing our environmental impacts and providing transparent disclosure. As an early adopter of renewable energy, we are leading the clean energy transition and managing the risk of climate change through our bold vision to serve customers with 100% carbon-free electricity by 2050. By reducing carbon emissions, we also decrease other environmental impacts, such as air emissions, waste and water use. Our communities can count on us to protect the environment, and this includes supporting stewardship and conservation projects through our community investment — projects that further enhance and preserve the places where we live, work and do business.

Social Responsibility

Supporting the people and places we serve

We serve people, helping to run their homes and businesses and providing comfort and convenience. We continually strive to create value by offering products and services that our customers want and need, and operating in a way that protects the public and drives economic growth. We support our local communities as a partner in economic development, by assisting customers in need, and giving of our time, talent and financial resources. Building stronger communities is fundamental to our business.

Running a successful business and cultivating a strong workforce

Now more than ever, we are investing in the processes, technology and clean energy that will enhance our service for the future, while maintaining reliable, affordable energy. Our focus is on continuous improvement. This means carefully managing costs and a responsible supply chain, encouraging innovation and ensuring a secure and resilient energy grid for the future. As an employer, we provide a safe and rewarding workplace, one that values people and their contributions and reflects the diversity and strengths of our communities. We operate in a rapidly changing industry, driven by new technologies and evolving customer expectations. Cultivating a workforce that is equally dynamic, highly skilled and customer focused is one of our most important investments.

Governance

Maintaining strong governance practices

Our proven track record of strong financial and operational performance is rooted in a foundation of sound corporate governance and oversight. It starts at the top through a board that is diverse, engaged and experienced. With a strong independent lead director, 12 of our 13 board members are independent and five self-identify as female and/or minority. Together, they bring the diverse perspectives and experience our company needs to be successful. Through annual strategy sessions and other best practices, we effectively manage risks and opportunities, including those related to our environmental and social responsibilities. Throughout Xcel Energy, we continue to foster a culture of compliance and ethical business conduct — one that is founded in our values: Connected, Safe, Committed and Trustworthy.

Throughout our Corporate Responsibility Report, we demonstrate our leadership and progress in fulfilling our social and environmental responsibilities. We cover performance across 24 issues that are associated with these responsibilities and that are important to our industry and to those we serve. We put special emphasis on 10 focus areas that our stakeholders identified as being of most interest to them through a survey conducted in early 2017.

Aligning Corporate Responsibility with Corporate Strategic Priorities

Through our strategic planning process, the board of directors and executive leadership team identified three strategic priorities that represent the keys to our continued success in achieving our vision to be the preferred and trusted provider of the energy our customers need. These priorities include:

- Lead the clean energy transition
- Enhance the customer experience
- Keep bills low

Strong alignment exists between these strategic priorities and our corporate responsibility. The table below demonstrates this alignment to our corporate responsibility focus areas.

	Strategic Priorities	Corporate Responsibility Focus Areas
Social Responsibility	**Enhance the Customer Experience** • View our work through customers' eyes • Make it easy for customers to do business with us • Offer products and services that our customers value • Help strengthen our local communities **Keep Customer Bills Low** • Carefully manage our costs • Continuously improve how we work to improve efficiency without compromising safety or reliability • Keep total bill increases at or below the rate of inflation	**Affordable Energy.** Transform our cost structure to become more efficient and customer focused, while investing in projects that reduce fuel and other expenses for customers. **Reliable Energy.** Deliver strong system reliability and outage response capabilities. **Public Safety and Employee Safety.** Ensure individuals living and working near our facilities are aware of potential hazards and respond safely to them.
Environmental Responsibility	**Lead the Clean Energy Transition** • Serve customers with cleaner, reliable energy through increased ownership of wind and solar generation and continued operation of our nuclear fleet. • Invest in the grid, including advanced technologies and transmission that enable more renewable energy • Reduce carbon and other emissions, improving environmental performance • Encourage and help enable the electrification or implementation of low-carbon solutions in other industries	**Energy Efficiency.** Support customers and the communities we serve in attaining their energy conservation goals. **Renewable and Advanced Clean Technologies.** Increase the use of economic renewables and position the power grid as a platform for new energy services. **Greenhouse Gas Emissions and Air Quality.** Continue to pursue a cost-effective clean energy strategy to reduce carbon and other air emissions.
	The Foundation of All Our Efforts **Corporate Governance.** Ensure sound corporate governance and a culture of compliance by focusing on strong practices, independent oversight and shareholder rights.	

Corporate Responsibility Governance

Corporate responsibility is embedded throughout our organization and integrated into our governance processes. With strong leadership from our board of directors and executive management team, along with engaged leaders and organizations across the company, we are able to effectively manage risks and opportunities and drive strong performance across a spectrum of corporate responsibility issues.

The table below describes key aspects of our corporate governance that cover corporate responsibility.

Board Oversight	Our board of directors, led by the chairman, president and CEO, oversees corporate responsibility-related issues and initiatives. • Board committees and responsibilities related to corporate responsibility include: – The Governance, Compensation and Nominating and Audit committees oversee respectively the Code of Conduct and corporate compliance. – The Operations, Nuclear, Environmental and Safety Committee oversees environmental strategy and compliance, safety and operational performance, customer service levels and all aspects of excellence in delivering electricity and natural gas service to customers. – The Finance Committee oversees our clean energy investments, investor relations and financial health. • The board follows a regular meeting schedule that ensures it is able to consider and address key issues, including those related to corporate responsibility. In addition, it conducts an annual strategy session to consider new and emerging trends, consult with outside experts and assess current strategies and initiatives.
Executive Oversight and Management	The executive team plans and executes on strategies designed to achieve Xcel Energy's priorities, including corporate responsibility-related issues and initiatives. • The executive team is responsible for the strategic direction of the company and sets key initiatives, including growth plans, the clean energy strategy and other corporate responsibility efforts. They consider evolving customer trends and preferences, industry and technology needs affecting our business, developments in the external landscape and policy considerations. • Strategies and key initiatives are crafted and executed to strike a balance between reliability, affordability and environmental impact. • Our executive compensation is tied directly to company performance, specifically reliability, cost management, customer satisfaction, public and employee safety, achievement of carbon emission reduction goals and financial performance.
Business Area Management	While the entire organization supports our corporate responsibility efforts, specific issues are directly tied to individual areas to manage. We use effective performance management techniques and compensation design to align employees around successful execution of our goals and efforts. • General Counsel: Ethics and compliance • Corporate Secretary: Governance, ethics and compliance, strategic planning and disclosure • Operations: Energy affordability and reliability, fuel diversity, advanced grid and environmental performance • Customer and Innovation Office: Energy efficiency, customer programs and satisfaction, economic development, security and emerging technology • Human Resources: Labor practices, safety and community giving • Financial Operations: Risk management, investor relations and disclosure • Nuclear Operations: Nuclear generation, safety and waste management
Operating Companies	Our operating companies execute on our corporate strategy and develop and implement plans that address corporate responsibility and fulfill our economic, environmental and community responsibilities. • Operating company staff engages with stakeholders to help ensure mutual priorities and goals are addressed. • Policy staff develops strategy and engages on energy policy issues, including climate change, environmental policy and sustainability strategy. • Resource plans are developed and analyzed for meeting customers' future energy needs and achieving clean energy and other stakeholder priorities.

Stakeholder Engagement

As a regulated, public utility we can only be successful if we have insight into the needs and priorities of those who our business relies on and serves. Because of this, we regularly engage with our stakeholders and seek opportunities to better understand their interests, concerns and emerging trends. The feedback we receive from these interactions helps to inform our business plans and strategies.

Xcel Energy's stakeholders are those individuals and groups who affect or are affected by our business operations. They fall within the following general categories:

- Customers
- Employees
- Communities, including local government officials, non-profits and community organizations, and advocacy groups
- Legislators and regulators
- Investors

Our stakeholder engagement is far-reaching and transparent, with regular, ongoing business interactions and special meetings, presentations and proceedings before our state public utilities commissions. Our account management and state and local affairs and community relations teams have always engaged with large customers, city and county governments, influential organizations and individuals, state legislators and policy makers to discuss important service and energy-related issues and projects. We annually report on our lobbying and political contributions, which are governed by corporate policy. We also have a strong presence in our service territory through our community giving and volunteer support of community initiatives and programs.

In addition to our regular, ongoing engagement, we conducted a special survey in 2017 to better understand our local stakeholders and their priorities related to corporate responsibility. Results from the survey helped to inform the content and focus for this report, as well as our efforts in general.

How We Engage

The table below outlines our regular, ongoing engagement with stakeholders and our response to stakeholder interests.

Stakeholder group	Engagement	Key interests	Our response
Customers	• Customer Contact Center • Key account managers • Personal account representatives for customers in need • Customer advocate process • Surveys and focus groups • Customer communications and account information • Special events and meetings	• Energy service start and stop • Service reliability and timely outage response • Electric and natural gas safety • Energy affordability and money saving opportunities • Easy billing and online account management • Information privacy • Neighborhood construction or repair work • Renewable and clean energy	• Public safety materials, programs and advertising • Extensive energy-saving programs and tips • Online account management programs and the Xcel Energy app • Online outage map and improved outage communications • Construction project communications • Data privacy process • Renewable choice programs • Clean energy leadership and strategy

Stakeholder group	Engagement	Key interests	Our response
Employees	• Leadership meetings • Employee meetings and webcasts • Bargaining unit negotiations and communications • Employee surveys • Employee Communications • Quarterly performance connections	• Market-based compensation and benefits • Professional development • Communication • Recognition • Community involvement • Engagement in energy policy	• Total Rewards statement and tools, such as My Financial Future planning tool • Connect4Performance performance management • Professional development resources and tuition reimbursement • I Deliver and Innovator recognition awards • New employee orientation • Print, electronic and video communications • Volunteer activities and paid-time-off program • United Way campaigns and matching gift program • Business Resource Groups • Diversity and inclusion education • Wellness programs • Grassroots political events and political action committees
Communities	• Project-specific stakeholder meetings and open house events • Community relations staff • Partnerships and local memberships • Franchise agreements • Presentations and speaking engagements • Sponsorships and community events • Volunteer projects	• Public safety • Project input and communication • Community giving • Economic development and jobs • Support for community goals • Renewable and clean energy • Energy efficiency	• Public safety programs • Project communications • Xcel Energy Foundation giving and United Way campaigns • Employee volunteer programs and community board support • Programs for customers in need • Clean energy leadership and strategy • Renewable choice and energy efficiency programs

Stakeholder group	Engagement	Key interests	Our response
Legislators and regulators*	• Policy and legislative involvement • Governmental and regulatory staff • Regulatory filings and proceedings • Political action committees and grassroots employee events • Speaking engagements	• Affordable energy • Reliable energy service • Renewable and clean energy • Climate change and greenhouse gas emissions • Environmental protection • Responsible corporate governance	• Continuous improvement and cost management • Clean energy leadership and strategy • Renewable choice and energy efficiency programs • Corporate environmental policy and environmental management system • Voluntary emissions reduction initiatives • Highly rated corporate governance program
Investors	• Investor meetings, presentations and teleconferences • Participation at investor conferences • Website • Annual report, 10-K, 10-Q, proxy, financial press releases and other disclosures • Annual shareholder meeting	• Stock appreciation and company growth prospects • Meet earnings per share guidance • Meet long-term EPS and dividend growth objectives • Deliver a superior total shareholder return relative to our peer group • Solid credit ratings • Financing needs • Favorable regulatory environment • Transparency • Risk management	• Corporate strategy that includes a fair return on investment, utility business investment and stakeholder alignment • Clean energy leadership and Steel for Fuel strategy • Highly rated corporate governance programs • Investor relations communications and mobile app

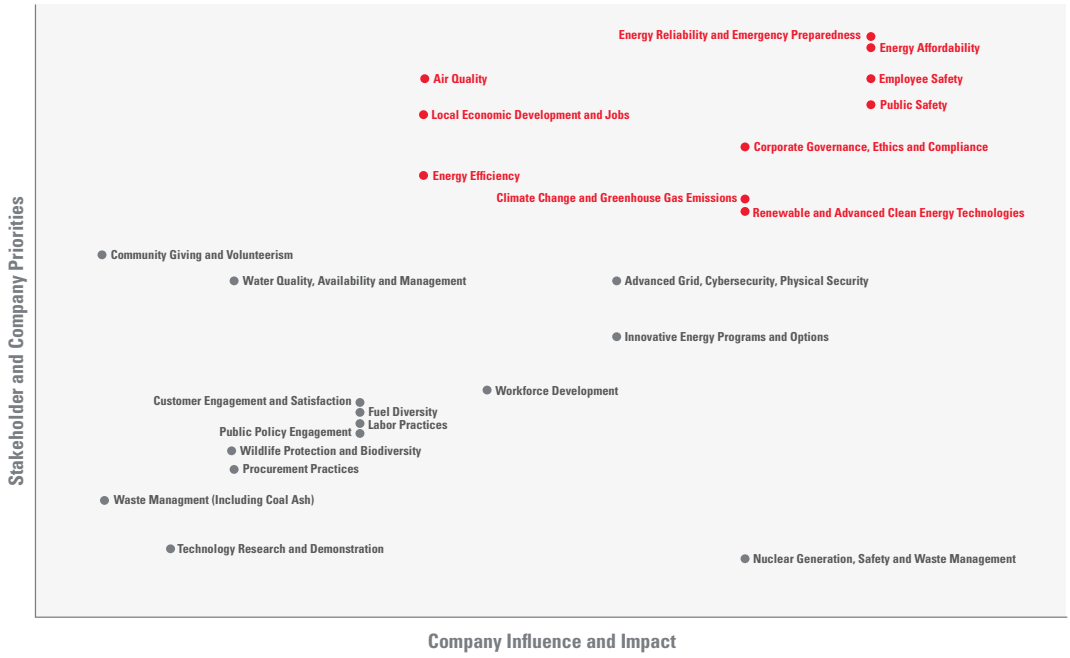
Identifying Areas of Focus for Corporate Responsibility

Based on stakeholder engagement, research and participation in a number of industry and sustainability forums, we have identified 24 major corporate responsibility issues for Xcel Energy. These issues closely align with the sustainability issues facing the entire electric sector, as identified through an extensive study conducted by the Electric Power Research Institute's Energy Sustainability Interest Group — of which, Xcel Energy is a member.

In early 2017, using the Global Reporting Initiative methodology to guide us, we conducted an online survey with nearly 1,000 stakeholders to understand which issues are currently most important to the individuals and organizations within our service territory, as well as within our own organization. The results are provided in the chart below.

While all of these issues are important, we consider the issues highlighted in red to be focus areas. They reflect the current priorities of our stakeholders and for our company where we can have a meaningful impact. Consequently, to the extent we are successful in addressing and managing these issues, we will be delivering real value.

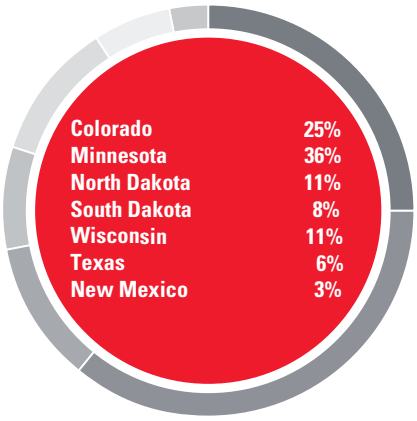
Corporate Responsibility Focus Areas



Methodology for Corporate Responsibility Survey

The corporate responsibility survey was conducted internally and designed to have stakeholders identify their top priorities for Xcel Energy's corporate responsibility efforts. Xcel Energy's executive leadership also answered the survey to understand our internal priorities. Altogether, the survey was distributed to nearly 1,000 internal and external stakeholders across our eight-state service territory. Approximately 26% of potential respondents participated. The respondents represented a good mix of our local stakeholder categories and our service territory.

Respondent by State



Respondent by Stakeholder

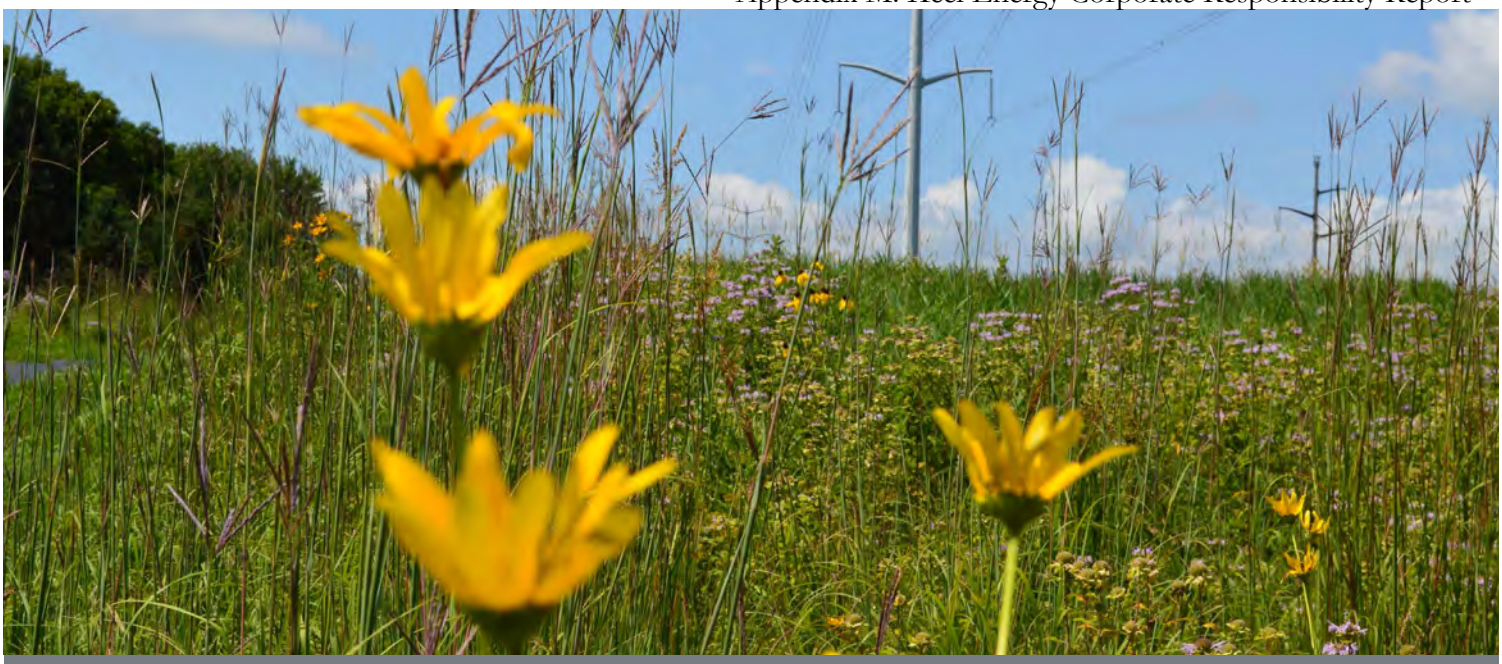
The survey was based on the 24 corporate responsibility issues we identified for our company. These issues were based on our experience through regular stakeholder engagement, research and participation in a number of industry and sustainability forums. Many of these issues align with industry research conducted by the EPRI Sustainability Interest Group.

Throughout the survey, respondents were asked to prioritize the corporate responsibility issues in different ways and had the opportunity to identify new issues. First, the respondents ranked their priority issue within five categories. These are the responses shown in the graph in the section above. Second, respondents listed their top five corporate responsibility issues without any categories. Lastly, respondents could add new issues and describe any sustainability goals that their own organizations may have and how Xcel Energy could help meet those goals.

Xcel Energy corporate responsibility issues and definitions, including 10 identified focus areas highlighted below.

Advanced Grid, Cybersecurity, Physical Security	Upgrading the power grid with advanced technologies to improve reliability and security; protecting important systems and infrastructure from unauthorized access or attack; drilling emergency scenarios both with and without external stakeholders to ensure effective response to potential events
Air Quality	Reducing air emissions other than greenhouse gases from our operations, including nitrogen oxides, sulfur dioxide, mercury and particulate matter, both through emissions controls and fleet transformation
Climate Change and Greenhouse Gas Emissions	Managing and reducing the greenhouse gas emissions from our operations, including carbon dioxide, methane and sulfur hexafluoride (SF6) through fleet transformation
Community Giving and Volunteerism	Giving both time and money to local nonprofit organizations; supporting energy assistance programs for customers in need
Corporate Governance, Ethics and Compliance	Ensuring adherence to the rules, practices and processes that direct and control our company; setting ethical expectations and values and monitoring adherence to applicable laws and regulations
Customer Engagement and Satisfaction	Working with customers to understand their needs and improve the service and products we provide; ensuring a positive customer experience with interactions that are focused, simple and transparent; meeting our scorecard objective of building customer loyalty
Employee Safety	Adopting, enacting, and promoting effective programs that protect the health and safety of employees and contractors
Energy Affordability	Ensuring electricity and natural gas bills are affordable for consumers
Energy Efficiency	Providing programs to help customers take control of their energy usage and save money, including traditional rebate programs and advanced home solutions
Energy Reliability and Emergency Preparedness	Providing electricity and natural gas with few to no interruptions; being prepared to quickly repair outages caused by storms or other incidents
Fuel Diversity	Minimizing dependence on any one energy source by using a diverse mix of sources to generate electricity
Innovative Energy Programs and Options	Offering programs that give customers choice over their energy sources, such as helping them access more wind and solar power or helping them fuel electric or natural gas vehicles
Labor Practices	Adopting responsible practices related to employee pay, benefits and equal opportunity
Local Economic Development and Jobs	Working with the community to attract and support new business development and economic growth

Nuclear Generation, Safety and Waste Management	Maintaining Xcel Energy's nuclear fleet that provides reliable, carbon-free electricity, in a way that ensures safety and emergency preparedness; safely handling and storing solid waste from nuclear generation
Procurement Practices	Doing business with responsible, local and/or diverse suppliers for the equipment, materials and services we purchase
Public Policy Engagement	Engaging and collaborating with policymakers and providing input on proposed legislation and regulations
Public Safety	Providing education to prevent accidental contact with electric power lines and natural gas pipelines; protecting the public around our facilities and facility operations; ensuring effective emergency response to public safety issues around our facilities
Renewable and Advanced Clean Technologies	Increasing electricity generation from clean, renewable energy sources, including wind farms and solar power plants; deploying advanced technologies to reliably manage higher levels of wind and solar energy
Technology Research and Demonstration	Participating in projects to test advanced energy technologies that have potential for providing customers with new products and services in the future; supporting industry research efforts through financial contributions, staff involvement and demonstration projects
Waste Management	Preventing and reducing waste produced from our operations, including coal ash; reusing or recycling waste instead of disposing of it in landfills; operating power plants fueled by waste
Water Quality, Availability and Management	Ensuring the availability of water for electricity generation and all other users; protecting water quality
Wildlife Protection and Biodiversity	Avoiding or minimizing impacts to protect species and their habitats; supporting raptor habitat and providing education and conservation opportunities on raptors
Workforce Development	Maintaining a workforce of the right size and skill profile, includes our talent management strategy and diversity and inclusion efforts; engaging in community efforts to develop pipeline of future employees; providing competitive employment opportunities and supporting diverse business resource groups



About this Report

Publication Date: May 2019
Reporting Period: Jan. 1 – Dec. 31, 2018
Date of Previous Report: May 2018 (for 2017)
Reporting Cycle: Annual
Report Boundary: Xcel Energy and its four regulated subsidiaries
Contact Point: corporateresponsibility@xcelenergy.com

Xcel Energy's annual Corporate Responsibility Report focuses on the company's environmental and social contributions, and is built on 24 issues that we have identified as important to our stakeholders and company.

This year marks the 14th year we have published the report. Our first Corporate Responsibility Report (formerly known as the Triple Bottom Line report) was published in April 2005, with the contents covering the 2004 calendar year. The report is published online, and to raise awareness for it, we print a highlights brochure that is distributed at our annual shareholders' meeting and at other events throughout the year.

How to Use this Report

Our ongoing goal for this report is to improve transparency and to meet the different information needs of the stakeholders that use it. With this in mind, we provide different levels of information.

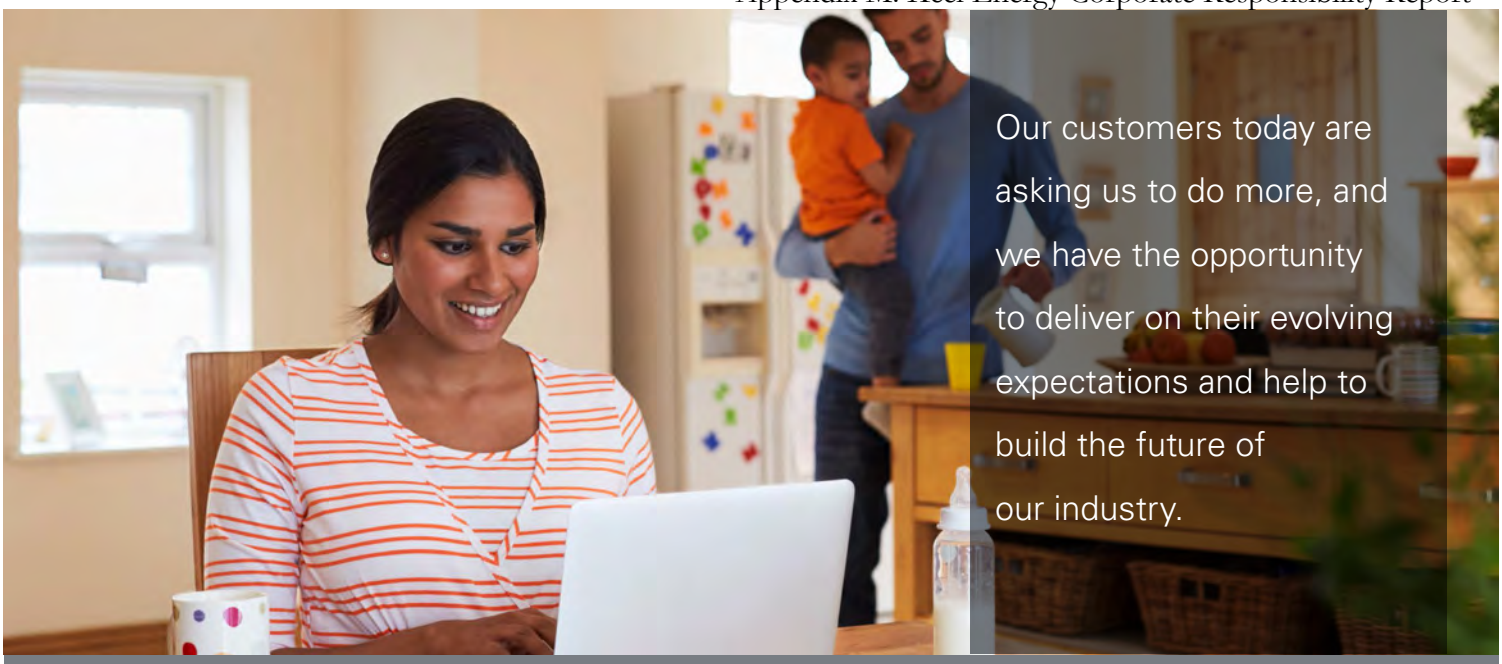
- The *CEO Message* from Xcel Energy's chairman, president and CEO, Ben Fowke, discusses our role in serving communities and our priorities and annual performance.
- The *2018 Highlights* page provides an introduction to Xcel Energy and a high-level look at our environmental, social and economic contributions for the year.
- The *Library of Briefs* offers a deeper discussion of our approach to managing specific topics — the content of the briefs covers the 24 corporate responsibility issues we identify in the Corporate Responsibility Governance section of the report.

- The *Corporate Responsibility Governance* section describes our corporate responsibility and how we govern it, along with our stakeholder engagement and 24 issues underpinning this report. It also demonstrates the alignment between with our corporate responsibility focus areas and corporate strategic priorities.
- For those interested in the numbers, we provide a *Performance Summary* that is a list of disclosures and also the *GRI Standards Content Index*.
- A full copy of the report, which includes all the content from this website, can be downloaded as a PDF. Past reports can be found in the report archive online.
- Xcel Energy publishes an Edison Electric Institute (EEI) environmental, social, governance and sustainability report, a new industry report that provides information in a measurable and consistent format for investors.
- Throughout the report, we also provide links to more information published in other corporate reports, such as the 2018 Annual Report, 2019 Proxy Statement or online at xcelenergy.com.

Global Reporting Initiative Guidelines

Xcel Energy continues to base its Corporate Responsibility Report on Global Reporting Initiative (GRI) guidelines, which we have used since 2008. This year's report is based on GRI's Standards in accordance with the Core option and the Electric Utilities Sector Supplement. We have tried to meet the intent and follow the standards as closely as possible; however, there are instances where we track information for disclosure differently or not at all, based on our company or stakeholder information needs.

Customers and communities



Customer engagement, satisfaction and energy affordability

Earning customer satisfaction and trust

Each and every time our customers engage with us, we want to make it easy for them and deliver a positive, best-in-class experience.

We understand that energy is a necessity in people's lives. Above all else, to earn their satisfaction and trust, we must first deliver on our responsibility to provide safe, reliable and affordable energy that is increasingly clean. This also means being there when customers need us most — whether they are experiencing a service outage, struggling to pay a bill or looking for ways to better manage their energy use.

Enhancing the customer experience is a strategic priority for Xcel Energy, and to fulfill it, we are focused on improving all levels and points of service for customers. We constantly manage the systems, processes and people we have in place to meet different customer needs and circumstances, and we are expanding the products and services we offer to support our customers even more.

2018 Results

- As we continue to focus on improving the customer experience during an outage, we worked to improve our internal processes in 2018. This included training employees on when and how to update estimated restoration times to provide customers with more timely and accurate information, coupled with reporting to emphasize process adherence. This ongoing effort is showing up in customer satisfaction perceptions. We moved ahead of 12 utilities in our peer set of 56 utilities from 2017 to 2018, placing us in the upper second quartile for outage communications.

- We continue to foster a workforce culture where all employees take ownership in ensuring a dependable, easy, enjoyable and personal experience for our customers. We launched Customer Experience Training, with more than 3,000 employees completing the in-person sessions that focus on: building a customer-centric mindset, ownership and personal accountability, and taking action. The goal is for all employees to complete the training in the next several years.
- Xcel Energy's average annual residential energy bills continue to be below the national average. Our average residential electric bills from 2009 to 2018 are 26% lower than average, and from 2008 to 2017, our natural gas bills are 14% lower than average.
- We provided approximately $51.9 million to customer energy assistance programs for the year that helped almost 198,000 individuals and families throughout our service area.

The Regulatory Compact

We operate under carefully regulated conditions that are determined in part by state public utilities commissions — a governing body that regulates the rates and services of utilities such as ours. In exchange for the exclusive right to provide electricity and natural gas services in certain regions, we agree to the following regulatory compact:

- **Duty to serve:** We cannot pick and choose our customers. We will provide service to any residence or business within our service territory that requests it under reasonable terms and conditions.
- **Cost of service pricing:** We cannot arbitrarily raise prices to levels beyond our costs. Pricing for our services is regulated by the costs we incur to deliver them.
- **Resource planning process:** Every few years, we go through a process to determine the resources necessary to serve customers' future energy needs. Resource plans must be reviewed and approved by regulatory commissions, and stakeholders can provide input on the plans through a public process.

In return, we are granted the ability to recover our costs of doing business and earn a reasonable rate of return. Although, this rate of return is not guaranteed — we have only the opportunity to earn it. To operate effectively in a closely regulated business like ours, it is imperative that we stay in sync with the current demands of the public and our policy makers.

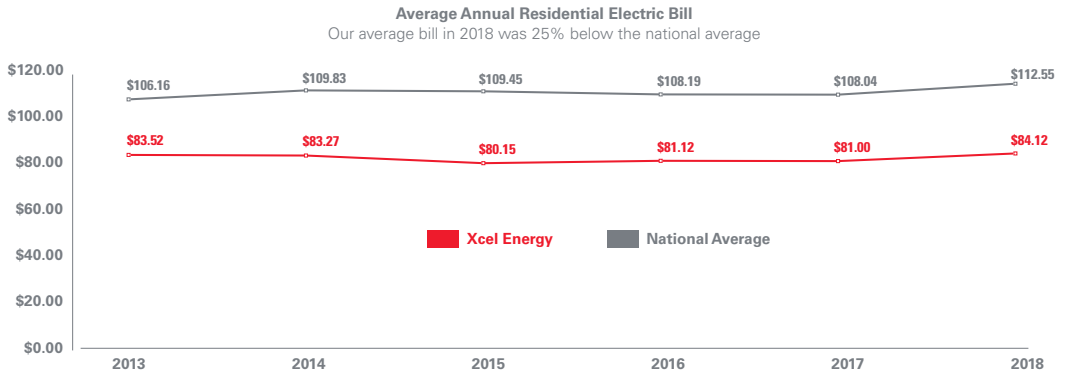
Managing Customer Energy Bills

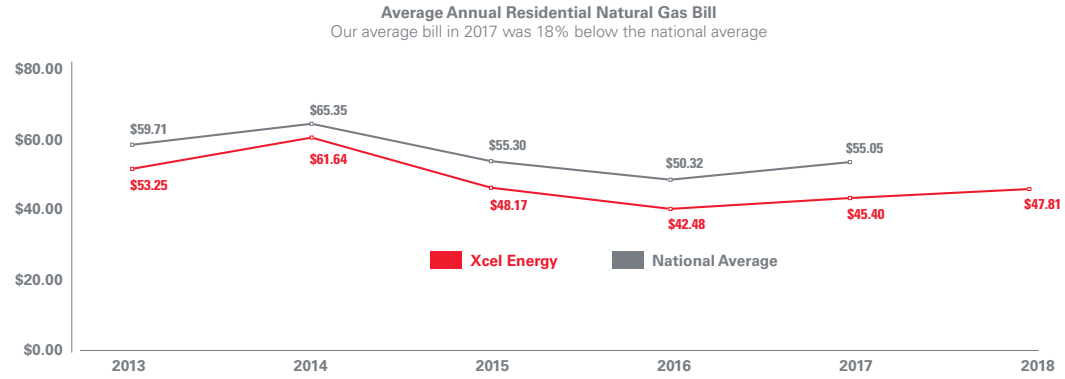
We continue to focus on the cost of service to deliver on our company's priority to keep energy bills low for customers. We saw an uptick in Xcel Energy's average residential electric and natural gas bills in 2018, although we continue to have among the lowest average residential bills in the country. We calculate that Xcel Energy customers over the past decade have spent $3,365 less on electricity and $1,007 less for natural gas compared to the national average.

Xcel Energy's lower than average customer bills are likely but not exclusively the result of:

- Our comprehensive portfolio of energy efficiency programs, as well as changing codes and standards that result in more efficient buildings and appliances
- Company-wide disciplined cost management
- Investments through our Steel for Fuel strategy, which calls for adding clean, renewable projects at a cost that is offset by the future fuel savings
- Growth in on-site or rooftop solar panels
- Increases in multi-family housing construction
- Weather differences, which can increase or reduce average bills for the year

Xcel Energy Comparison of Average Monthly Bills





Based on EIA bill trend data reported each year by utilities and revised by EIA in early 2019. Represents Xcel Energy annual average of monthly bills, excluding taxes and franchise fees; annual national natural gas bill information is not yet available.

Measuring Customer Satisfaction

We monitor customer perceptions of the company and our performance through several tools. The two most notable are the J.D. Power & Associates Electric Utility Customer Satisfaction studies and the customer transactional satisfaction studies that we implement with our partner, MaritzCX.

J.D. Power & Associates implements an industry-wide benchmark that provides details of our relationship with residential and small- to medium-sized business customers and how that compares to industry peers. For the residential electric study, we improved from low second quartile in our peer set in 2017 to high second quartile in 2018. Residential customers provided the most positive feedback in the areas of quality and reliable electricity service, efforts to develop energy supply plans for the future and total monthly cost of electric service. With business customers, Xcel Energy ranked in the second quartile in our peer set in 2018. Our highest satisfaction scores among business customers were for efforts to develop supply plans for the future and for actions to take care of the environment.

We also continue to demonstrate strong performance at our customer contact centers. Through regular transactional surveys in 2018, 85% of residential and business customers reported that they were satisfied with their transaction involving an agent at our contact centers. Similarly, more than 86% of customers reported their problem or issue was resolved on the first call to Xcel Energy. Our Customer Care organization sets annual goals with satisfaction and first call resolution, and we met or exceeded both of these in 2018.

Customers in Need

We work with state and local agencies and advocates for low-income customers to provide energy assistance to those in need. Our Personal Accounts department helps to monitor and assist customers who have medical needs or who are struggling to make their monthly energy payments. They can assist and make energy bills more affordable to income-qualified individuals and families by promoting special energy efficiency programs, arranging payment plans and providing energy assistance resources.

Our support of energy assistance includes:

- Public policy and advocacy supporting efforts on the state and federal level for funding of Low-income Home Energy Assistance Programs (LIHEAP)
- Funding for state and local energy assistance agencies and energy weatherization programs
- Encouraging our customers to contribute to statewide fuel funds via their Xcel Energy bills
- In-kind marketing and public relations to support energy assistance organizations and advocates for low-income customers

We encourage customers who are having trouble paying their bills to contact us to develop a payment plan and determine if additional assistance is available. In Minnesota and Colorado, we have medical exemption or affordability programs for low-income customers with special medical needs to help them with their utility bills.

We only disconnect service as a last resort if we are unable to resolve the issue or arrange a payment plan. For customers behind on their payments, we typically send a reminder notice 33 days after the unpaid bill is due and a disconnection notice 64 days after the original due date. In 2018, we disconnected service to a total of 64,635 customers. The majority of these customers were reconnected within 72 hours of the disconnect after they arranged payment plans or paid their bills in full. Heat-affected disconnections are not performed in our five Upper Midwest states during the heating season. In each of our states, our Customer Care leadership has the authority to suspend disconnections during extreme weather or other emergency situations.

Scam Awareness

Nationwide and internationally scammers continue to target utility customers, trying to take their money. Utility scam activity first spiked in 2014, and since then, we have combatted the problem by making technology changes and raising awareness to expose the tactics of scammers and help customers protect themselves.

Customer losses were down 8% in 2018 compared to the previous year, while the reported number of scam attempts was up, indicating customers may be increasingly informed around the danger scammers present. Since we formally began to address the issue, customer losses are down by more than half.

We are able to track both in-person and phone-based scam attempts thanks to the reports of customers. When we learn of heightened scam activity in specific locations, we promptly contact local media and use our social media channels to release information and alert customers. The data we collect is also used in partnership with law enforcement to investigate possible larger scam efforts and trends across our territory, with the ultimate goal of shutting down scammers. Xcel Energy security alone has shut down more than 250 phone numbers used by scammers to target our customers.

In addition, we joined Utilities United Against Scams in 2016, a collaborative of more than 100 utilities across the United States. Members share leading practices and updates about how scams are affecting their customers, as well as ideas and updates on what they are doing to spread awareness. The group was instrumental in establishing an annual awareness day — National Utilities United Against Scams Day — which takes place on the third Wednesday each November.

Data Privacy

Xcel Energy takes seriously our responsibility to protect company information, including the confidential information that we generate and receive about our operations, customers, employees, contractors and vendors. Our corporate policies and standards regarding information management and protection are designed to maintain the trust of the individuals and organizations we do business with.

We operate in a highly regulated industry that requires the continued operation of sophisticated information technology systems and network infrastructure. In the ordinary course of business, we use our systems and infrastructure to create, collect, use, disclose, store, dispose of and otherwise process information. Our employees and contractors are trained on information management and protection requirements.

Our Enterprise Security Services group helps ensure the protection of company information across all business units. This organization includes four main branches: Cyber Security, Enterprise Resilience, Physical Security and Security Governance and Risk Services. In addition, we have established a Cyber Defense Center and an Enterprise Command Center designed to investigate, respond, mitigate and remediate incidents and vulnerabilities that may involve company information.

Serving our customers involves working to keep them safe. We continuously promote public safety campaigns to raise awareness around the hazards associated with natural gas and electricity.

Public safety

Raising safety awareness

Our goal is for everyone who lives, works or gathers near our facilities to be aware of possible hazards and how to respond safely to them.

Ensuring the safety of our employees, customers and the public is a responsibility we take very seriously. To do this, we have comprehensive outreach programs that promote safe behavior among our customers, communities, emergency responders and third-party workers.

Ultimately, we aim to prevent accidents that can result in serious injury or death, property damage, costly repairs or fines and decreased service reliability. Most serious accidents involving the energy we deliver happen because someone directly or indirectly makes contact with an overhead electric line, digs into an electric or natural gas line, or fails to respond safely to the warning signs of a natural gas or electric emergency.

2018 Results

- Our company delivered its best-ever public safety performance during the year. We surpassed our annual target of 1.30 or fewer excavation damages per 1,000 locate requests by more than 8% as the number of third-party dig-ins to underground pipes and wires continued to decline and responded within an hour or less to 87% of customer calls associated with a suspected natural gas leak or other emergency.
- We opened new training villages in Minnesota and Colorado that will provide 600 to 800 employees and community emergency responders with the opportunity to train in a realistic setting. The villages can simulate more than 40 different types of natural gas leaks and recreate incidents that have occurred across the country.
- Customer recall of our safety advertising and perception of our commitment to public safety continue to steadily increase, as measured by customer survey responses.

- An advertising partnership among utilities to promote calling 811 before digging resulted in nearly 1.1 million total message impressions in April 2018 — national safe digging month.
- Xcel Energy linemen Kellen Schmidt and Scott Knight were instrumental in changing Minnesota's Move Over law, which now requires drivers to slow down or move over when approaching utility, construction and emergency vehicles stopped along two-lane roads.

Public Safety Awareness Efforts

Raising awareness about the dangers associated with activities near overhead and underground electric and natural gas lines is no easy task. We send direct mail to thousands of customers each year and offer free safety materials through fulfillment programs and partner organizations. We also offer online safety resources for emergency responders, public officials, elementary educators, students and their parents, and third-party workers.

We employ the following tactics to raise public safety awareness:

- Advertising
- Broadcast media appearances and outreach
- Email communications
- Event appearances
- Mailings
- Social Media
- Sponsorships
- Trainings and meetings
- Websites

Advertising

Xcel Energy's Always Delivering campaign launched in mid-2016 and continued to carry public safety messages throughout 2018. While the campaign uses simple language and consistent, entertaining visuals, as well as subtle humor and a friendly approach, we adjusted safety language to be a bit more serious and even more direct to make a quicker connection to our critical safety messages.

Advertising continues to be one of our most successful tactics for raising safety awareness. With an objective to reach as many customers as possible, we extended our campaigns to run year-round in 2018 and concentrated on high-impact media, such as television, radio and digital advertising. As a result, we increased total number of impressions by approximately 50%.

Outreach to Specialty Audiences

Throughout the year, we also focus awareness efforts on audiences that are influential or play an important role in supporting public safety. These audiences include:

- Emergency responders, such as firefighters and law enforcement, who may be first to respond to electric and natural gas emergencies
- Third-party contractors who may come into contact with power lines or natural pipelines as part of their jobs, including construction, roofing and tree care professionals, as well as agricultural workers and those who do excavation work
- Educators, including principals and superintendents, and teachers and students in second through sixth grades

We have fulfillment programs that annually distribute tens of thousands of brochures, booklets, DVDs, videos, posters, activity sheets, visor cards or other materials tailored to educate and inform these audiences of safety practices and hazards. Many of these communications are provided in both English and Spanish. We also direct these groups to use our e-SMART worker and e-SMART kids websites, as well as the Responding to Utility Emergencies online training that we sponsor.

In addition to materials and online resources, we provide in-person trainings and conduct numerous emergency drills for local emergency responders, and offer school and community safety presentations. There is an online course to encourage and train Xcel Energy employees who want to volunteer as Public Safety Ambassadors and conduct public safety presentations or participate in community events.

Public Safety Campaigns

Our public safety campaigns are targeted at communicating outreach messages in four key areas, including:

- Calling 811 before digging
- Staying at least 10 feet away from overhead lines to be safe
- Recognizing and responding to a possible natural gas leak
- Keeping natural gas meters clear of snow and ice

Call 811 Before You Dig

Accidental third-party excavation damage to underground electric and natural gas facilities not only interrupts service for our customers unnecessarily, it is a significant safety concern and remains the biggest threat to our natural gas distribution systems. Xcel Energy is a member of the Common Ground Alliance, a member-driven association committed to saving lives and preventing damage to underground infrastructure by promoting effective damage prevention practices. The association's most prominent initiative is the national 811 phone number that people can call to have underground utility lines marked before they dig.

Some of our outreach efforts to promote 811 in 2018 included:

- Launching an advertising partnership in Colorado and Minnesota. Together with Colorado 811, Centerpoint Energy and Gopher State One Call, we created a cohesive, separately branded message for calling 811 before digging.
- Sending semi-annual bill inserts with details about the importance of maintaining customer-owned service lines, and updating the semi-annual natural gas safety bill insert to include this information, so that this message will now be delivered quarterly.
- Participating in the National Excavator Initiative video as a subject matter expert for calling 811 and safe digging practices. Xcel Energy was joined by peer utilities, locate and excavation companies along with heavy equipment providers and operators.
- Collaborating in lighting the Lowry Bridge in Minneapolis green for National 811 Day, as well as Xcel Energy's Hiawatha and Midtown substations in Minneapolis.
- Participating in the third annual Colorado 811 5K run, which included a post-run safety event with electric safety demonstrations and bucket truck rides, local emergency responders, Red Cross information and games. The number of registration spaces was increased again in 2018 and registration was full before race day.
- Sponsoring JJ Harrison, the 811 Rodeo Clown, with over 1 million FaceBook followers.
- Participating in and sponsoring the Colorado Mock Line-strike Drill attended by more than 300 excavators and emergency responders.
- Sponsoring the Cold Zone Hazmat Conference in Minnesota for 200 attendees from seven states.

Electric Safety

Contact with electricity can result in serious injury or even death. We continually work to engage and educate the public, urging them to stay away from equipment, such as overhead lines, underground lines, downed power lines and damaged electrical equipment.

Some of our outreach efforts in 2018 included:

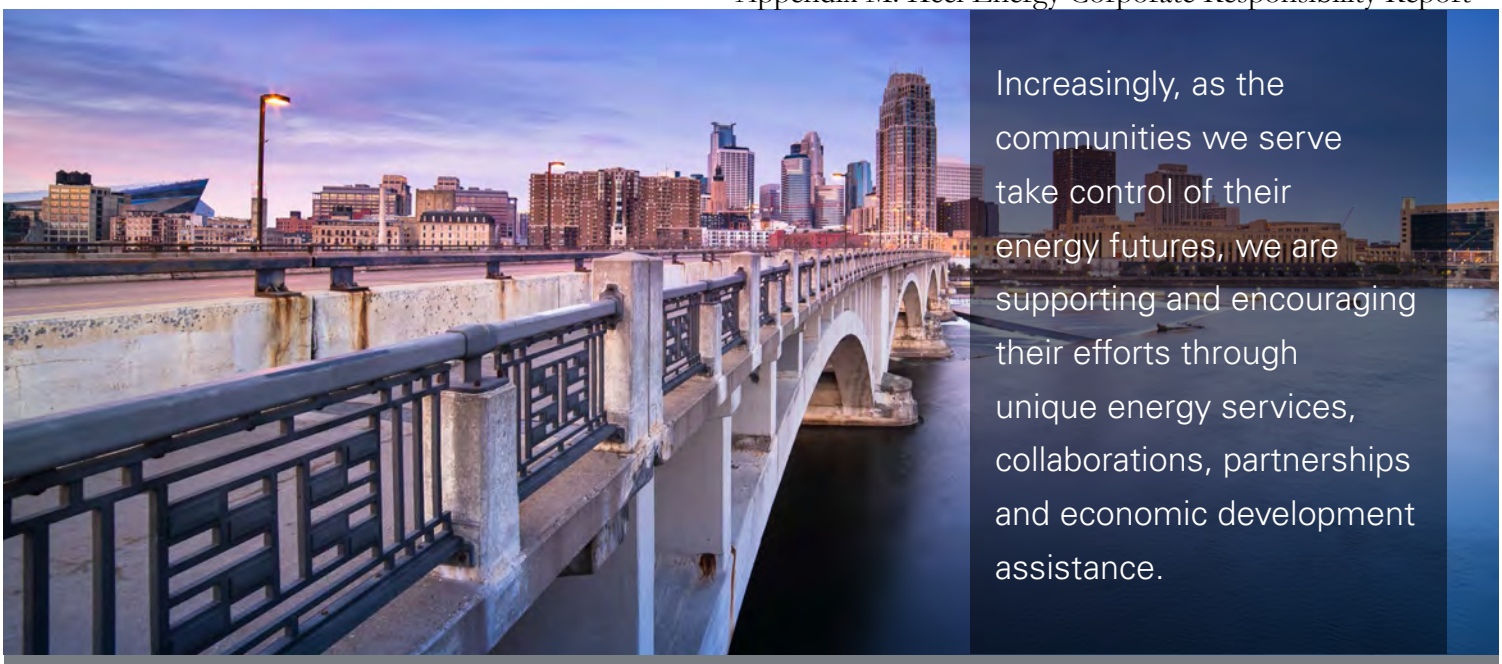
- Conducting dozens of public electric safety demonstrations featuring the Power Town arcing display.
- Conducting electric safety demonstrations at the Minnesota State Fair for our 29th year. We had 72 employees volunteer nearly 200 hours to educate approximately 30,000 fair attendees about electric and natural gas safety and calling 811 before you dig.
- Including safety messaging with our press releases and social media during severe weather.
- Providing thousands of electric and natural gas safety pamphlets at public safety events throughout our service territory.

Natural Gas and Pipeline Safety

While keeping the public safe is a core value for Xcel Energy, it is also a requirement when it comes to natural gas pipeline safety. We must meet the American Petroleum Institute Public Awareness Programs for Pipeline Operators Recommended Practice 1162. This involves taking steps to increase awareness about the safety of our facilities and energy service that build trust among stakeholders, including customers, communities, investors, employees, public officials, at-risk workers, educators and the industry.

We annually distribute materials through our membership with the national nonprofit Pipeline Association for Public Awareness and our participation in state-specific pipeline associations, as well as Minnesota's Community Awareness Emergency Response association. Through these organizations in 2018, we helped distribute more than 111,000 safety guides, books and newsletters to excavators and to public and emergency officials in states where we have natural gas distribution and transmission pipelines. We also participated in and helped sponsor many pipeline emergency responder meetings in our states and provided additional, in person pipeline safety trainings to hundreds more emergency responders.

Twice a year, we send safety information designed to share details about staying safe around natural gas to all of our natural gas customers with their bills. The bill inserts include a special mercaptan scratch-and-sniff badge that helps to educate customers on how a natural gas leak smells. Customers that receive electronic bills can request the insert with the mercaptan scratch-and-sniff badge.



Economic development and jobs

Partnering with communities

We play a valuable role in supporting local economies as an energy provider through our electric and natural gas service and our partnership.

With our ongoing investment in infrastructure — the plants, pipes, poles and wires that make up our business — we generate tax revenue, purchase goods and services and employ local workers. But, our connection and contribution to local economies goes much deeper than this.

By working side-by-side with local chambers of commerce and economic development organizations, we provide energy expertise and a valuable service that can help attract and retain area business. After all, for many businesses, energy is an important consideration for where they locate — it may be their largest expense or the focus of corporate sustainability goals. By offering a complete package of energy solutions, including a comprehensive portfolio of renewable and energy-saving options, along with competitive prices and outstanding service reliability, we are helping our communities successfully compete for business, something that supports all of our bottom lines.

2018 Results

- Through our focus on economic development, we generated and supported over 85 new business prospects for our communities in 2018. Of those, nine located and began doing business within our service area, supporting nearly 1,950 jobs and $750 million in capital investment.
- We filed a plan with regulators in early 2019 to provide renewable energy to a proposed Google data center to be located on Xcel Energy property adjacent to our Sherco Generating Plant in Becker, Minnesota. Consistent with transition plans developed in partnership by the company, Becker and Sherburne County, the project will add tax base and generate jobs for the community affected by the planned retirement of the plant's two oldest coal units. If approved, the Minnesota Department of Employment and Economic Development estimates the project will result in nearly 2,000 construction jobs, 50 full-time jobs and general economic growth of almost $150 million.

- Xcel Energy supported legislation in Colorado that was adopted to support economic development and new customer growth in the state. It allows utilities to offer negotiated, economic development rates to customers that require a new minimum electric load of three megawatts. The legislation also allows utilities to expand already authorized renewable programs to provide up to 20 megawatts of renewable energy for a customer that meets the criteria under the economic development rate program.
- Since 2014, Partners in Energy has worked with 37 communities to develop energy action plans — 20 in Minnesota and 17 in Colorado. Working with these communities to provide outreach delivered strong results for the year, including more than 49,000 participants in Xcel Energy efficiency programs and 15,500 participants in renewable energy offerings.
- We signed Memorandums of Understanding to establish Energy Future Collaborations with eight communities in Colorado. Customers in these communities represent approximately 32% of our retail load in the state, and the communities reflect a cross-section of the varied municipalities we serve — from rural to urban and mountain locations.

Xcel Energy Direct Economic Impacts

2018 Economic Value Generated (in millions)

Total revenues	$11,537
Electric utility revenues	$9,719
Natural gas revenues	$1,739
Other operating revenues	$79

2018 Economic Value Distributed (in millions)

Electric fuel and purchased power costs	$3,854
Cost of natural gas sold and transported	$843
Employee compensation, including wages and benefits	$1,983
Property tax payments	$442.9
Franchise fees	$190.8
Community investment	$63.1
Interest charges and financing costs	$652
Dividends paid	$730

Energy Future Collaborations: A Proactive Partnership Approach

Through Energy Future Collaborations, Xcel Energy is taking a new approach and uniting the specific energy goals of communities with our company's services and expertise to achieve shared objectives. The proactive collaborations are aimed at addressing a wide range of priorities, including how best to:

- Advance specific reduction carbon and renewable energy targets
- Reduce a city's carbon footprint
- Maximize energy efficiency programs
- Support economic development
- Integrate emerging energy-related technologies into area homes and businesses

The relationship-driven approach taps into many existing Xcel Energy programs and offerings but also focuses on uncovering creative solutions to new ideas and needs. From Xcel Energy's standpoint, not only do we develop a more meaningful relationship with some of our largest customers — our communities — but the collaborations provide an opportunity to inform key leaders and community members about our business and significant initiatives. Ultimately, the collaborations can help increase support for company initiatives that support community goals, such as the Colorado Energy Plan and the company's carbon reduction vision.

We have signed Memorandum of Understandings (MOU) for Energy Future Collaborations with eight diverse communities including: Alamosa, Breckenridge, Denver, Lakewood, Louisville, Lone Tree, Nederland and Westminster. We also believe the collaborations can be replicated with other cities and towns throughout Colorado, as well as in other jurisdictions.

With the MOUs in place, the company and the communities develop work plans involving a number of projects, along with objectives, timelines, resources required, funding needed, metrics for success, reporting measures and ultimate deliverables. We have finalized work plans with six of the eight communities and are on track to complete the other plans this year. An important point about the new framework is that the MOU guiding principles allow flexibility, but also protect nonparticipants from things like cost shifts.

Partners in Energy

Xcel Energy has a program and special team to support communities in achieving clean energy, economic development and energy conservation goals. The effort, known as Partners in Energy, started in fall of 2014 and is targeted at communities with the objective of helping them identify their future energy goals and develop strategic plans to drive activity. We then provide the resources to put the plan into action, supporting communities as they implement projects designed to achieve their goals.

Local governments play a larger role in choices around energy, and through the program, we can work with communities to support development and implementation of energy action plans that they own. Partners in Energy is unique in that it provides the opportunity to connect directly with community officials and organizations to help them meet their goals, leveraging our entire portfolio of energy solutions including efficiency, renewable and even payment programs. Typically, a community brings ideas and resources, while Xcel Energy offers direction, guidance and project management. We learn what communities prioritize and identify potential gaps where we can provide products to meet their needs and help them reach their goals. In return, the partnerships help to raise awareness and increase participation in Xcel Energy's current conservation and renewable energy offerings.

An energy action team is a group of local residents, business owners or energy stakeholders who work to develop the community's energy action plan and oversee its implementation. They are often the local leaders who work with Partners in Energy while connecting with their community. Action plans are based on community needs, resources, leadership commitment and the local vision for energy use in the future. Strategies to gain local support may include educational workshops, outreach at local events and promotional outreach including newsletters or personal canvasing — all approaches designed to gain recognition, participation and spread awareness to local residents.

Each community determines its goals, and we work together to drive success. We also help communities to track and report progress. In 2018, we expanded to reach and support even more communities through the following improvements:

- Planning services broadened to assist communities that did not have the need or resources to develop a full energy action plan.
- In-person programming was introduced to deliver educational resources to community leaders while providing opportunities to network and learn from the experience of others.
- The program's online presence was expanded to give participants a place to access their individual community documents, plus other resources critical to making informed choices around energy in today's rapidly changing energy landscape

Focus on Economic Development

Xcel Energy is leading local economic development activities in the communities it serves. We start by providing a competitive solution that meets customer needs. This includes offering outstanding reliability and customer service, combined with favorable pricing on our nationally recognized renewable energy and efficiency options.

We have developed strong partnerships with local, state and regional economic development organizations to support opportunities for customer and economic growth. In 2018, our Corporate Economic Development team attended more than 35 national conferences and industry events to promote economic development opportunities across our service area. This work focused on developing relationships to expand business development in all eight states where we operate.

We continue to focus on serving top industry clusters that represent the leading employers and capital investors within our service area.

These include:

- Aerospace and defense contractors
- Data centers
- Refrigerated storage warehouse and distribution
- Food and beverage processors
- Industrial manufacturing
- Medical device, instrument and supply manufacturing
- Oil and gas

Our team tracks trends that affect the growth of these industries to identify new service options and programs that can facilitate continued growth of these key industries. We develop deep-dive customer analytic reports to better understand individual customer needs and create individualized action plans that can enhance our relationship we these customers. We host Business Expansion and Retention meetings with key accounts to strengthen our existing relationships and explore matters that are of mutual interest that go beyond energy. Through these efforts, we can explore new product offerings and promote policies that anticipate customers' future needs.

Our Certified Site program provides business prospects with real estate options to increase their speed to market in locating their operations. In 2018, an inventory of 41 certified sites was identified throughout our eight states. These sites have undergone rigorous review of more than 120 data points to attract business development. We work directly with site representatives including landowners, developers, municipalities and economic development organizations to develop the data and complete the certification process. A nationally recognized site selection expert reviews the reports and validates the data and its significance for identifying prominent real estate options for potential users. Information on Xcel Energy's Certified Sites is available on xcelenergy.com.

Minneapolis Clean Energy Partnership

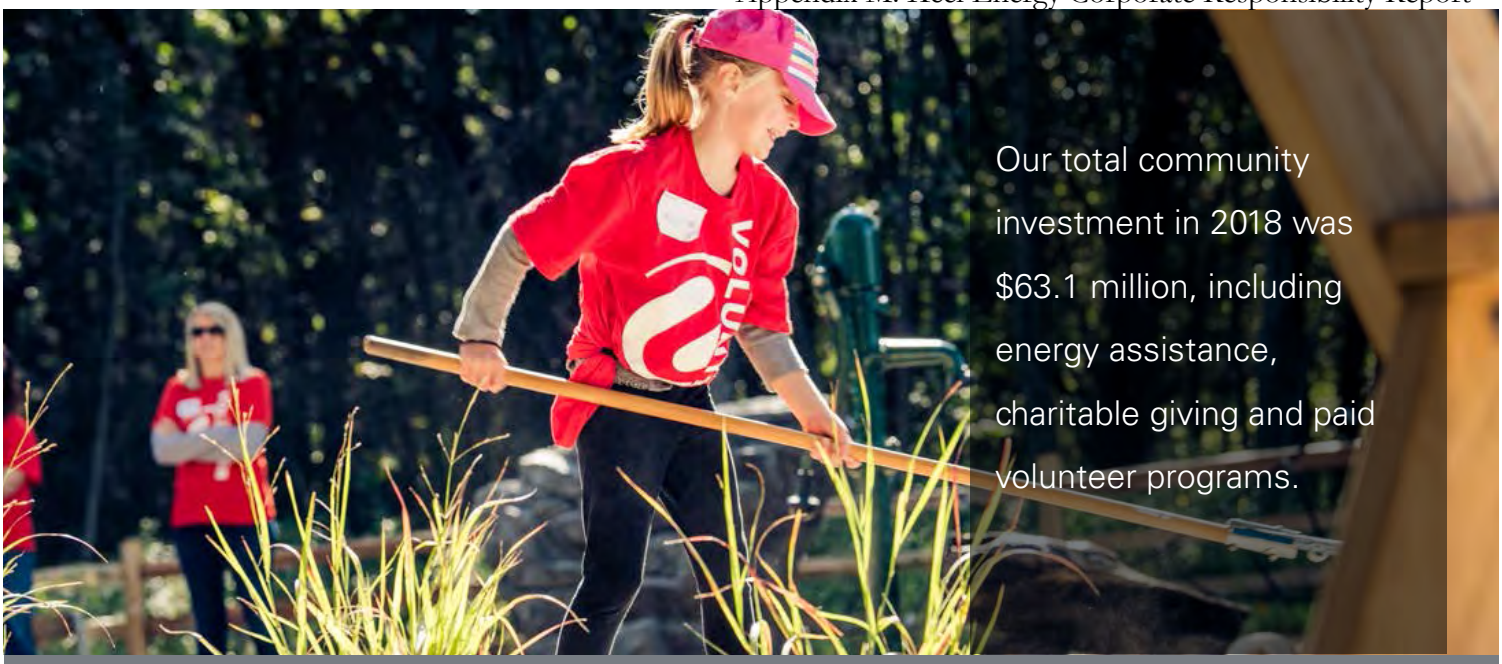
The city of Minneapolis, Xcel Energy and CenterPoint Energy teamed up to form a novel Clean Energy Partnership (CEP) in 2014 in support of the city's Climate Action Plan and 2040 Energy Vision. Now in its fifth year, the partnership continues to build on a long history of collaboration to explore innovative approaches and enhanced outcomes in energy efficiency and the use of renewable energy in Minneapolis and create longstanding community impacts. The partnership provides a leadership framework through which the city and utilities can work together to prioritize, plan, coordinate, implement, market, track and report progress on clean energy activities in the city.

The Clean Energy Partnership has approved the following priorities:

- Achieve energy efficiency in the industrial, commercial and residential sectors
- Make clean energy accessible through financing tools
- Make the city more sustainable or resilient through increased local renewable energy

The 2019-2021 work plan was approved by the board in late 2018. Xcel Energy partnered with the city on pilot projects including, developing a plan to decrease city enterprise energy consumption 10%, installing electric vehicle infrastructure to enable earlier transition of city fleet, and a focused effort to work with our business customers. We are also working with the city to build a community solar garden with a focus on low-income subscribers where we will target energy efficiency efforts to decrease the energy usage of the solar garden subscribers. The partnership continues to explore equitable access to clean energy jobs through study and project implementation, and we are working on energy disclosure tools to help the city implement new energy requirements.

We continue to help the city progress towards its clean energy goals through our precedent setting transition to a cleaner generation mix as well as by helping city residents and businesses save energy and increase options in our renewable choice programs. According to the partnership's latest annual report, released in mid-2018, citywide greenhouse gas emissions are down 20.4% from 2006 levels, exceeding the city's 2015 reduction goal of 15%.



Community giving and volunteerism

Corporate citizenship

We are committed to making a positive impact — as an energy provider, environmental steward, good neighbor and community advocate.

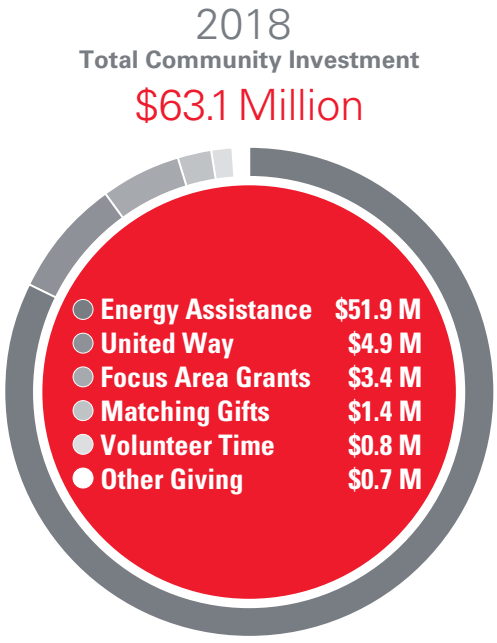
Xcel Energy serves hundreds of cities and towns across eight states. Through our active investment in their infrastructures and the energy we provide, we are literally connected to and serve as an integral member of those communities.

We understand our company's success is directly tied to the success of our communities. That is why investing in them through charitable giving and sharing our time and talents is fundamental to how we do business.

2018 Results

- Xcel Energy employees volunteered more than 90,000 hours and served on over 400 community, chamber and nonprofit boards. During the past year, we improved our tracking of volunteer and board participation because we use the information to measure community engagement.
- Through programs funded by our focus area grants, more than 450,000 students benefitted from science, technology, engineering and math education — an essential field of study for our future workforce and for the economy as a whole.
- The Xcel Energy Foundation contributed $60,000 to relief efforts following the Lake Christine, Spring Creek and other wildfires that burned almost 120,000 acres in Colorado in early summer. The funds helped to replace damaged equipment for the fire departments and other emergency responders who managed the wildfires.

- For National Philanthropy Day, the Association of Fundraising Professionals recognized the Xcel Energy Foundation as an Outstanding Foundation that is demonstrating an exceptional commitment through its strategic financial support and its encouragement and motivation of others to take leadership roles in philanthropy and community involvement.
- The Amarillo Branch of the National Association for the Advancement of Colored People (NAACP) honored Xcel Energy with its Diamond Jubilee for the company's support of its efforts. In this Texas community, we have funded and presented scholarships as part of the NAACP's spring scholarship luncheon for more than a decade and have consistently sponsored the group's educational and fundraising programs.
- Junior Achievement of Northwest Wisconsin recognized Xcel Energy as its Outstanding Community Partner of the Year for the company's commitment to helping area youth with financial literacy, work readiness and entrepreneurship. The organization serves a district of approximately 18,000 students in classrooms across 20 Wisconsin counties, most of which Xcel Energy serves.
- Xcel Energy was nominated as Corporate Supporter of the Year by the Black Data Processing Associates (BDPA) Twin Cities chapter. The award recognizes the efforts of corporations that support BDPA's mission to increase participation of people of color in the information technology field. For a number of years, we have provided the organization with financial support, volunteers and internship opportunities.
- Xcel Energy was a recipient of a Colorado Business Committee for the Arts Award, a statewide recognition that honors companies and individuals for their outstanding partnerships and engagement with the arts. We were nominated by several of our arts and culture grant partners including Cleo Parker Robinson, Dairy Arts Center, 40 West Arts and the Alamosa Live Music Association, among others.



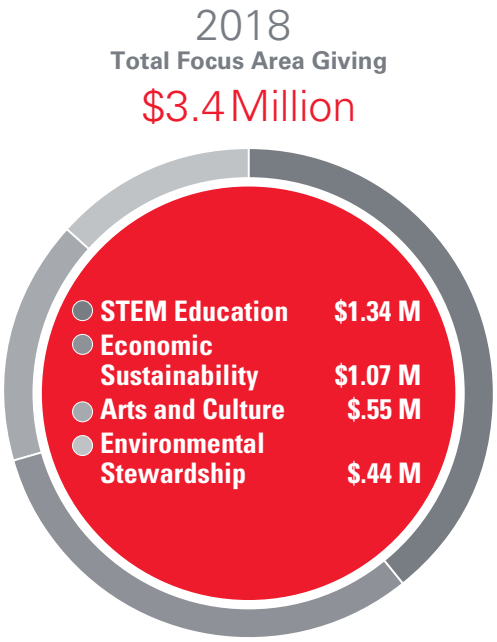
Xcel Energy Foundation

The Xcel Energy Foundation is our company's charitable arm that oversees giving and volunteer programs. Its mission is to use the collective knowledge, resources and skills of our staff and colleagues to make a positive impact in communities throughout our service territory.

The foundation generally focuses its support in four areas:

- **STEM Education (science, technology, engineering and math):** The economic growth and future of the communities we serve relies on the educational systems and programs that produce a quality workforce for tomorrow. Just like other businesses in the community, Xcel Energy's future success relies on having a workforce that is educated and well trained.
- **Economic Sustainability:** Employment levels directly impact a community's economic prosperity, and ultimately, quality of life. We believe that all of our customers should have the skills and opportunity to be successfully employed so we support organizations that promote workforce development and economic self-sufficiency.
- **Environmental Stewardship:** Our communities count on us to produce energy responsibly and to conserve natural resources. While we do all we can in our operations to meet these expectations, we can do more by supporting organizations and programs that work to protect and enhance the natural environment.
- **Arts and Culture:** Thriving arts and cultural activities are a key component to vibrant and strong communities. With a mission to help create desirable communities in which to live, we support programs that increase the opportunities and accessibility of arts and cultural programs to all.

In 2018, the Xcel Energy Foundation contributed over $3.4 million in grants to promote our primary focus areas of STEM education, economic sustainability, environmental stewardship and access to arts and culture. Altogether, 380 nonprofit organizations received grants averaging about $9,000 each.



Employee Involvement

Our employees are active members of their communities, where they live and work. We support this commitment by offering a number of programs that encourage their involvement, including:

- **Volunteer Paid Time Off (VPTO):** Full-time employees are eligible for up to 40 hours per year to volunteer for nonprofit organizations in our service area to help strengthen the communities we serve.
- **Dollars for Doing:** The Xcel Energy Foundation matches each hour an employee volunteers with a $10-per-hour contribution to the nonprofit, up to 100 hours annually per employee.
- **Volunteer Energy:** Groups of employees and retirees that volunteer together on a project are eligible for Volunteer Energy funding of up to $1,000 annually, which goes to the associated nonprofit from the Xcel Energy Foundation, in appreciation for the volunteer effort.
- **Matching Gifts:** The Xcel Energy Foundation matches dollar for dollar any employee and retiree charitable donations of $50 or more, up to $750 for nonprofit organizations and up to $2,000 for higher education institutions.
- **United Way:** the Xcel Energy Foundation sponsors an annual United Way campaign and matches the pledges of employees, retirees and contractors.
- **Day of Service:** Xcel Energy hosts a special volunteer day where employees demonstrate collectively their community spirit.
- **Board Service:** Throughout our service territory, we currently have hundreds of employees serving on nonprofit boards, with some employees serving on multiple boards.

United Way Campaign

Xcel Energy has a long-standing tradition of supporting United Way and the community organizations it assists. Each year, we sponsor an employee campaign that for seven consecutive years has raised well over $2.5 million annually in employee and retiree pledges, which the company matches.

The campaign is a fun and rewarding part of working at Xcel Energy, with a number of special fundraising events — from chili cook-offs to sport tournaments. This includes a popular "dress down" badge that employees can purchase which gives them a pass to wear jeans to work and significantly boosts fundraising.

Combined with the company match, the campaign in 2018 raised more than $4.9 million to support United Way programs and hundreds of nonprofit organizations throughout Xcel Energy's service territory. More than 4,000 employees and retirees contributed about $2.72 million in pledges, surpassing the campaign goal by 7%.

In addition, employees in our Texas and New Mexico service area support United Way's Day of Caring each spring. More than 70 employees volunteered in 2018 to lend a hand to complete improvement projects at several local nonprofit agencies.

2018 Day of Service

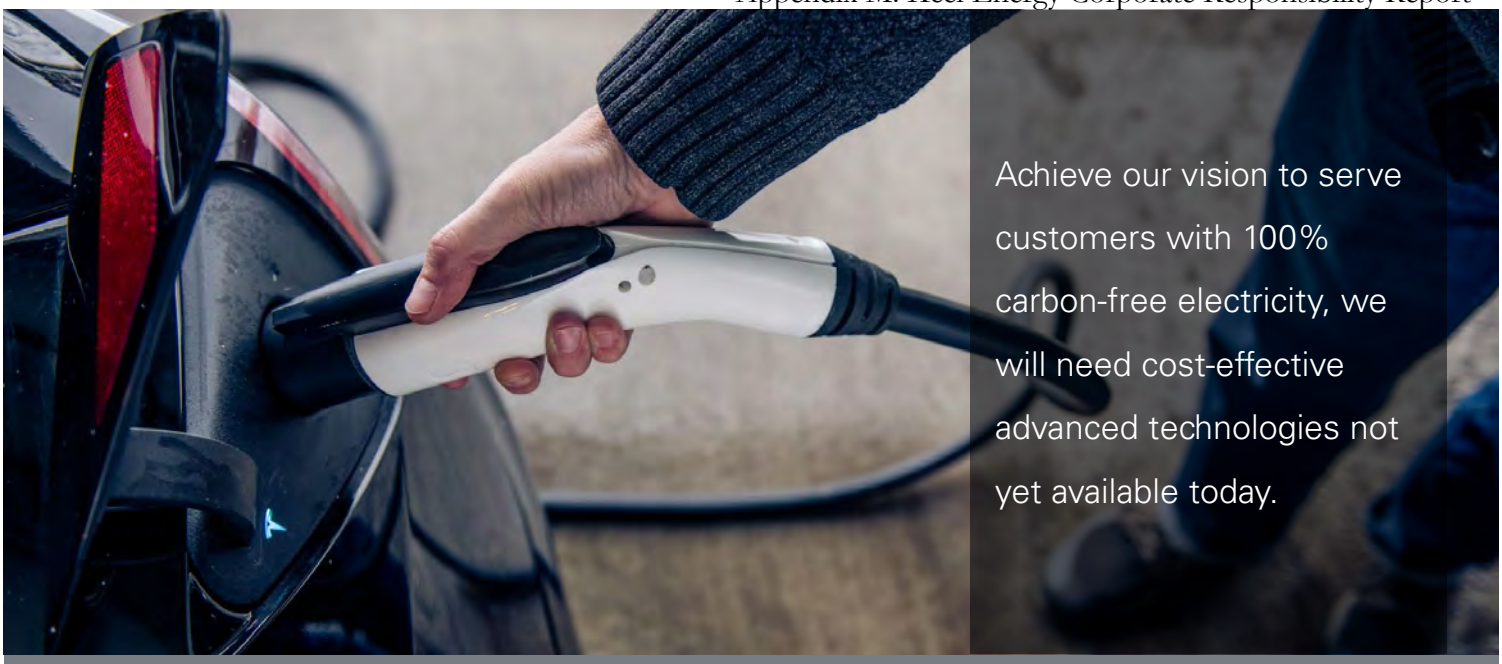
More than 4,600 employees, retirees and family members, along with some friends and customers, came together in September to volunteer to better their communities by participating in Xcel Energy's eighth annual Day of Service. The volunteers joined together at 116 project sites across Colorado, Minnesota, South Dakota, North Dakota, Michigan and Wisconsin to dig, plant, paint, cut, sort, organize and much more on behalf of a variety of community nonprofit partners.

In total, the effort contributed approximately 13,800 volunteer hours to support our local communities, valued at more than $429,000.

Energy Education

We want our customers to know how their energy is produced and delivered. To help achieve this objective, we support energy education in a number of ways. Most of our major non-nuclear power plants provide public tours for their neighboring communities, and through our online Energy Classroom, we offer educational resources for teachers and students.

Through a special community program in New Mexico, we support solar energy education for customers and schools. Our solar education center in Roswell demonstrates different technologies for collecting sunlight to generate electricity. We own four photovoltaic systems located on partner sites that are available to help teachers with energy curriculum specifically developed for New Mexico classrooms.



Innovative energy programs and technology research and demonstration

Energy innovation

Rapidly evolving technology is changing customer preferences for more sophisticated products and services, and those customer preferences are driving change in how we serve our customers.

Within the next decade and beyond, we will have more change in our industry than we have experienced in the last half century, driven largely by technology. Through collaborations with researchers, technology developers, venture investors and others in our industry, we actively monitor and stay abreast of developments in emerging and advanced energy technology. We also have underway a number of pilot and demonstration projects that are testing the real-world application of cutting-edge technologies and are serving our customers today.

This work has become increasingly important because of our ambitious carbon reduction goals. To realize our vision for a carbon-free future, we will need clean 24/7 technologies to integrate high levels of renewable energy, as well as other advanced technologies.

Advanced technologies also make our operations more efficient, safer and cost effective. As powerful tools emerge to transform our work, they can reduce our costs, improve productivity and enhance the service we provide, benefitting our customers through their overall experience and the costs they pay.

2018 Results

- We launched our first set of voice actions using the Google Assistant as a seamless way for customers to access information to improve energy efficiency in their homes. It is part of a new collaboration with Google to deliver tools that customers can use to manage energy use.
- In Minnesota, we announced plans to build on our clean energy leadership by investing more than $25 million to increase access to electric vehicles (EVs), and help drivers and fleet operators start driving electric.

- In Colorado, we proposed and received approval for a residential demand response battery pilot. It will study the integration of batteries into utility systems, battery performance and customer preferences. We are seeking to work with two to four battery vendors and engage up to 500 customers during the pilot term, which will begin in late 2019 and continue for up to two years.
- We continue to gain valuable insights from our investment in Energy Impact Partners, which has now invested $325 million in 25 companies that support a number of advancements from distributed energy resources to storage, electric vehicles, advanced data analytics, microgrid applications, cybersecurity and other clean energy technologies.
- Xcel Energy became the first public utility to receive permission from the Federal Aviation Administration to inspect transmission lines using drones flown beyond the operator's visual line of sight.
- We began piloting the use of bots to drive speed and accuracy in performing routine tasks within our Finance department, enabling employees to shift time to higher-value work.

Advanced Grid Intelligence and Security

Through our Advanced Grid Intelligence and Security (Advanced Grid) strategic initiative, we plan to transform the grid into an intelligent, integrated network that securely, efficiently, reliably and safely integrates distributed energy resources.

We have started building Advanced Grid technology infrastructure in Colorado where regulators have approved the initiative. This includes:

- Upgrading to advanced meters for 1.5 million Colorado electric customers from 2019 to 2024.
- Installing Integrated Volt-VAR Optimization technology (IVVO) from 2017 to 2022 which allows customers' appliances to run more efficiently, and in turn, use less energy and potentially reduce monthly bills.
- Implementing the Field Area Network (FAN), a new communications network that provides the infrastructure necessary to enable two-way communications between intelligent devices on the grid — such as advanced meters — and the control center. These communications include automatically notifying us when customers lose or regain power, improving our ability to identify outages and more efficiently deploying repair crews. The FAN continues to be installed in the Denver metro area and the entire network will be complete by 2023.

We began deploying FAN advanced field devices in 2018 and implemented a secure, two-way private network that will function as the foundation for the technology in Colorado, as well as Minnesota, where we have regulatory approval for a time-of-use pilot that will launch in 2020. The network enables the secure flow of information between control centers, new advanced devices in the field and our customers.

The FAN infrastructure is critical for when we begin deploying advanced meters to Colorado and Minnesota customers in 2019. We plan to begin rolling out advanced meters to 13,000 Denver metro area customers in late 2019. Through the pilot in Minnesota, 17,500 meters will be deployed giving 10,000 customers from the Hiawatha West and Midtown area of Minneapolis and customers in the Westgate area of Eden Prairie the opportunity to save money by using electricity when it is less expensive to generate and deliver.

Electric Vehicles

The future of transportation is dramatically changing, and as more electric vehicle options become available, a growing number of customers want to reduce their carbon footprint through the cars they drive. We are uniquely positioned to support our customers and communities and to work with electric vehicle (EV) stakeholders to make this change and ensure it truly benefits customers, the environment and the power grid we all rely upon.

Through our EV strategy, we are focused on:

- Raising awareness and increasing access to information on the benefits of EVs
- Helping reduce the upfront costs of infrastructure needed to charge EVs
- Establishing time-varying rates and smart charging technologies to ensure that EVs can charge as much as possible on low-cost, low-carbon energy

While EVs create a significant opportunity for drivers and fleet operators to save on fuel and other costs, barriers exist to wider-scale adoption, such as customer awareness, high up-front costs and the availability of charging infrastructure. We can help overcome these barriers by developing new services, piloting them and then rolling out our most successful ideas to customers on a broader scale.

We developed a portfolio of innovative pilots in Minnesota that will benefit drivers, customers and the environment. The initiatives and pilot programs focus in three main areas: home charging, public charging and fleet operations. This includes a two-year pilot in Minnesota to 100 residential customers that offers a turn-key approach to charger installations by reducing the upfront costs for equipment and providing off-peak pricing benefits. Future options could include a new subscription service that would provide drivers with a set bill for EV charging and equipment each month, and we are exploring dynamic digital tools to help customers understand all their options when it comes to vehicle choices, pricing options and charging solutions.

For public charging, our fast-charging-corridor pilot will seek to leverage public and private funds to increase the availability of fast-charging stations on highways and other major corridors. We are also working with the cities of Saint Paul and Minneapolis on a pilot to support a charging network for everyone, including those who may not own vehicles. Through a partnership with HOURCAR, a local, independent, nonprofit car-sharing service, Xcel Energy will support a new, all-electric, one-way car-sharing service and other innovative mobility services in the Twin Cities. This project is intended to increase access to the benefits of electric transportation, including those in low-income, under-served communities.

We also plan to make it easier and more affordable for large fleet operators like Metro Transit, the Minnesota Department of Administration and the City of Minneapolis to integrate electric vehicles into their fleets. We will provide the electrical infrastructure needed to charge the first eight of Metro Transit's electric buses and are looking to provide charging infrastructure for the State of Minnesota and the City of Minneapolis EV fleets and other customers over time.

We expect to expand our EV efforts to other states, and as we pursue our EV Plan, we are focused on these objectives:

- Empower customers with information, tools and options
- Increase access to electricity as a transportation fuel in an equitable manner
- Encourage efficient use of the power grid and integrate renewable energy
- Improve air quality and decrease carbon emissions
- Ensure reliability, interoperability and safety of equipment
- Leverage public and private funding opportunities
- Provide benefits to all customers, both EV drivers and non-EV drivers
- Ensure transparency and measure results

Colorado Innovative Clean Technology Projects: Battery Demonstration Projects

Our Colorado Innovative Clean Technology program was first approved in 2009 to test emerging technologies intended to lower emissions. We have and continue to test several new technologies and evaluate their cost, reliability and environmental performance on a small, demonstration scale before determining whether to deploy them more widely for our customers.

We have two battery-storage demonstration projects currently under the program:

- As demand for solar energy at our customers' homes and businesses increases, we are examining how battery storage can help integrate higher concentrations of customer solar energy on our system. Through a project in Denver's Stapleton neighborhood, six homeowners have received Sunverge customer battery systems to test with their rooftop solar installations. We also have installed six larger grid battery systems, supplied by Northern Reliability, Inc., in right-of-ways or easements.
- Through a public-private partnership, Xcel Energy, Panasonic and Denver International Airport are collaborating to test a battery storage system that can both serve as a microgrid to provide backup power to Panasonic's Denver headquarters and to support Xcel Energy's grid at other times. As part of the project, Xcel Energy owns a 1.3 MW-AC solar carport installation and a 1 MW/2MWh lithium ion battery. Panasonic also owns a 0.20 MW-AC solar array located atop its building, which is tied into the system.

With both projects, we are testing various ways to operate the battery systems, and are evaluating and analyzing performance. Testing will be completed in 2020. We are finding that the battery systems perform well and are learning many things that will influence future battery system design and associated integration with our system.

Drones

We are using unmanned aircraft systems or drones in a number of applications. From inspecting power lines to wind turbine blades and evaluating substations for equipment upgrades, drones are making these tasks easier, safer and helping to reduce costs.

We were the first in the nation to enter into a partnership for safety with the Federal Aviation Administration (FAA), and now hold one of five of the partnerships, along with GE, Amazon, Google, and Florida, Light and Power. In 2018, we increased the use of drones as we became the first public utility in the country to receive FAA permission to fly drones beyond the operator's visual line of sight and without a visual observer to inspect transmission lines. The flights, which began last summer and continued monthly through the year, are part of a program to prove the value of using unmanned aircraft to inspect critical infrastructure in the power industry.

As a regulated utility we are required to inspect electric transmission lines on a routine basis. Traditionally, we have conducted these inspections with helicopters and foot patrols. Using drones to inspect our 24,000 miles of electric transmission lines delivers value on many fronts, starting with ensuring reliability for our customers thanks to better data. It is also safer for employees, especially in remote mountainous areas, and less costly. As technology improves, the cost to operate drones continues to fall, which will save even more money for customers.

The program started in Colorado, and pending FAA approval, we plan to expand the transmission inspection program in other states in 2019.

Energy Impact Partners

With the pace and scale of emerging technologies and changing customer interests, the energy industry is evolving in ways it never has before. Xcel Energy joined Energy Impact Partners in 2015 as an opportunity to better understand technology's impact on our business and to drive greater efficiency and innovation as we meet customer needs.

EIP is a collaborative, strategic investment platform that provides capital primarily to clean-tech companies that seek to optimize energy consumption and improve sustainable energy generation. Our planned $50 million investment over five years represents a new era for us, where we move beyond clean energy implementation for our customers and into the clean-tech investment space.

Xcel Energy was an original participant in the collaboration that now includes more than 15 utility and industrial participants. By joining with peer companies, we gain greater visibility into the business models and technologies of promising companies and have the opportunity to influence emerging business models so that energy companies and third parties can collaborate and grow together. Also EIP brings together energy companies from around the world to share diverse, global perspectives and insights into policy and regulations, helping position us for new trends, rules and other requirements in the states we serve.

We are gaining insights that are helping inform our strategic decisions and how we conduct our business across the organization from energy supply to distribution, customer solutions and cybersecurity.

Electric Power Research Institute (EPRI)

Through our long-time membership with EPRI, we gain insights into the challenges and opportunities for using advanced clean energy technologies and reducing carbon emissions. This includes EPRI's work on electric system resiliency, climate scenario analysis and greenhouse gas reduction goals, as well as integrating renewables, electric vehicles, combined heat and power, customer demand response and energy efficiency.

EPRI also informs our regulators and customers on technical and economic issues, opportunities and challenges related to the use of new grid technologies, including large-scale and customer-sited distributed energy resources, such as energy storage and distributed generation. In this collaborative research environment, we can engage with the industry, technology developers and other stakeholders who test and evaluate new technologies and products, develop tools and methodologies to analyze the effects of distributed energy resources on the power delivery network and optimize their use.

GridNXT at SolarTAC

The Solar Technology Acceleration Center (SolarTAC) in Aurora, Colorado, is a world-class facility for demonstrating and validating advanced solar and distribution grid technologies in a real-world, grid-connected environment. Even before the project's grand opening in 2011, Xcel Energy recognized the potential benefit of the facility and signed on as an original founding member.

Our investment has paid off for customers. Not only have we tested important battery projects at the site, solar technologies fine-tuned at SolarTAC serve our customers in Colorado and New Mexico with more cost-effective, efficient solar energy. Through testing, solar developers were able to make adjustments for adverse weather conditions before installing the technology in our service areas.

To continue evolving with technology and developer needs, the 74-acre site has transitioned to become a test-bed for solar, storage and other distributed energy enabling products and components. GridNXT at SolarTAC now supports the demonstration of advanced technologies for integrating distributed generation and storage, including microgrid capabilities at the edge or end of the electric distribution system.

Renewable and advanced clean technologies

Renewable energy

Xcel Energy operates in some of the country's best regions for producing wind and solar power, and we are putting these resources to work for customers.

Increasingly, the customers and communities we serve want their energy from clean, renewable sources, and we are delivering. Renewable energy plays a vital and growing role in our energy supply and future plans for meeting customer needs.

As wind and solar technologies continue to improve, prices decline, making it possible to operate a reliable, affordable power grid with significant levels of renewable generation. When it comes to managing cost and reliability, scale matters. We are focused on increasing the use of large-scale, universal wind and solar energy because these resources are significantly more economical and can provide energy for all customers at half the cost compared to smaller, distributed resources.

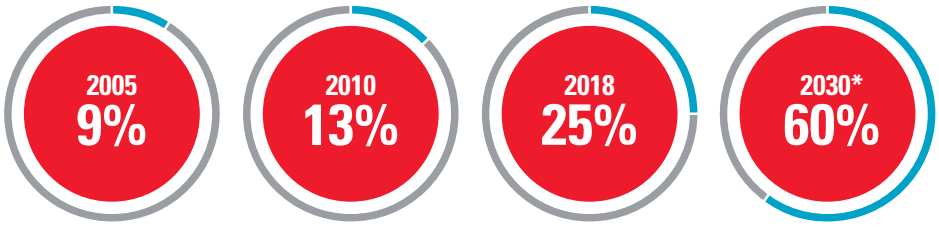
We also recognize that some customers want more renewable energy, beyond what is currently in our energy supply, including some of our business customers and communities that have set goals for up to 100% renewable energy. To meet this need, we continue to expand and improve our voluntary renewable choices, enabling customers to achieve their goals.

2018 Results

- Since 2005, we have been a national leader in wind energy, and according to the American Wind Energy Association, are ranked the No. 2 utility wind provider with nearly 8% of the country's wind capacity on our system.
- Our new, 600-megawatt Rush Creek wind project was completed and is estimated to produce enough electricity to power approximately 325,000 homes annually. It is the largest project we have built and is among the largest in Colorado, with 300 Vestas wind turbines manufactured in the state. The project injected $1 billion into Colorado's economy and is projected to help avoid 1 million tons of carbon per year.

- At year-end, we had 762 megawatts of large-scale, universal solar capacity and 7,288 megawatts of wind capacity — enough to power approximately 3.8 million homes. This includes 1,440 megawatts at wind farms we own.
- After its 2017 debut in Minnesota, our Renewable*Connect® program quickly sold out during its 2018 launch in Colorado. Early in 2019, we successfully transitioned 100% of Windsource® subscribers in Wisconsin to Renewable Connect, demonstrating high engagement and satisfaction with this new option. As customer demand for Renewable*Connect grows, we have proposed expanding the program in Minnesota and expect to propose an expansion in Colorado.
- Nearly 190,000 customers participate in renewable choice programs. Plus, we achieved a milestone of more than 1 gigawatt of distributed solar installed on our system since the programs began.
- The City of Eau Claire, Wisconsin, recognized Xcel Energy for making a difference and helping the city to become more sustainable through the company's efforts to increase renewable energy, efficiency and conservation.

Renewable energy is a vital and growing part of our energy supply.



*Results are estimated and reflect potential scenarios that achieve 80% reduction in carbon emissions by 2030; actual system depends on various factors, including regulatory approval of future plans.

Ramping Up Renewables: Steel for Fuel

Xcel Energy's Steel for Fuel strategy resonates with all types of stakeholders because it expands the company's renewable portfolio and delivers carbon-free energy without raising customer bills. Under the effort, we are adding renewable resources — the steel — at a net savings because the capital costs of the projects are more than offset by future avoided fuel costs.

Delivering on the nation's largest multi-state wind investment

Several years ago, we announced the addition of 12 new wind farms across seven states, totaling 3,680 megawatts of new wind capacity, enough clean wind capacity to power about 1.7 million homes annually. All the projects have now moved from the approval to execution phase. When complete, we will own about 70% of the new capacity, more than quadrupling our company-owned wind portfolio.

Our Rush Creek wind project was the first to be completed in fall 2018, and we are now building three wind farms to be completed in 2019: Hale (478 megawatts) in Texas, Foxtail (150 megawatts) in North Dakota and Blazing Star I (200 megawatts) in Minnesota. Nearly all 12 projects will be online by year-end 2020 to take advantage of the full production tax credit. Only the Dakota Range wind project will be complete in 2021 and is still low cost despite qualifying for a partial tax credit.

All of these projects must be built from the ground up, except for one. For about 20 years we purchased power from the Lake Benton wind project in southern Minnesota. Now we plan to buy and operate the project as part of our wind fleet once it is rebuilt in 2019 with new, more efficient turbines. By repowering an existing wind farm such as this, we are able to take advantage of existing transmission and other infrastructure. It is one of the reasons Lake Benton could successfully compete in the bidding process against other wind projects.

The Colorado Energy Plan

Under the Colorado Energy Plan approved by regulators in 2018, we will add 1,100 megawatts of wind energy from three new wind farms and the repowering of a fourth, existing wind farm. The projects include the 500-megawatt Cheyenne Ridge wind farm that we will construct and own. We will also add a 72-megawatt solar farm and three solar and battery storage projects, which combined incorporate 560 megawatts of large-scale solar and 275 megawatts of battery storage.

The solar-battery projects are located in different parts of Colorado, with one project in Adams County near the Denver metropolitan area and the other two in southern Colorado. The two projects in Pueblo County are the largest, with capacities of 100 to 125 megawatts and four hours of battery storage. They will help provide reliable generation capacity to replace coal power from nearby Comanche units 1 and 2, slated for retirement by 2026.

Economic benefits

In addition to providing affordable, carbon-free electricity for customers, all of these projects support economic development. Our 12 new wind projects are expected to create 2,700 construction jobs, 150 full-time jobs and generate $800 million in landowner lease and property tax payments over the lives of the projects. The Colorado Energy Plan is anticipated to inject $2.5 billion into the state's economy, including $1 billion from Xcel Energy.

Repowering plans

We continue to seek new, economic opportunities to expand our wind portfolio and have asked regulators for approval to buy two older wind farms in southern Minnesota, which are currently being repowered with the latest wind technology. We have purchased power from the Jeffers and Community Wind North projects over the past decade under long-term agreements. Adding the refurbished wind farms with a capacity of 44 and 26 megawatts, respectively to our own energy portfolio further supports our clean energy transition and will save customers money compared to long-term purchases. If approved, we would close on the completed projects by year-end 2019. We plan to pursue similar opportunities in the future.

Renewable Choice Programs

Just as customers want more control over their energy use, they also want more choice in how they engage with energy options. Our goal is to offer innovative solutions that enable our customers to meet their priorities around clean energy and the environment, while balancing these choices with the cost that all customers pay to support them.

We were an early adopter of voluntary green power back in 1998 with the introduction of our flagship program, Windsource. Since then, our program offerings have expanded to include options for community solar gardens, on-site solar and Renewable*Connect — our newest offering.

Through Renewable*Connect, customers can choose to make their energy up to 100% renewable through different contract options, such as month-to-month, five-year and 10-year terms. There is no equipment to install and customers can remain on the program if they move to a different home or business location within our service area.

Renewable*Connect exemplifies innovation. We have combined our program and regulatory experience and customer input to design the program so customers retain the renewable energy credits and rights to renewable energy claims. Renewable*Connect also keeps bills low for participating customers, while not increasing costs for nonparticipants. It is self-supporting through subscription fees, so nonparticipants don't pay more.

In Colorado, the program's energy is delivered from the new 50-megawatt Titan Solar facility, near Deer Trail, Colorado. The energy sources for the Minnesota and Wisconsin programs include the Odell Wind Farm and North Star Solar.

Participation in our other renewable choice programs continues to grow as well. In Minnesota, there were approximately 7,700 subscribers participating in our Solar*Rewards Community® program at the end of 2018. With more than 500 megawatts of capacity from 170 participating solar gardens, the program is easily the largest community solar garden program in the country, although the purchase rate for this Minnesota solar energy is two to four times higher than what we would pay from more cost-efficient energy sources. Our Colorado community solar garden program was one of the first in the nation and also continues to grow, quadrupling in size between 2017 and 2019.

In Wisconsin, our Solar*Connect Community® program is fully subscribed and continues to expand. A second community solar garden located in La Crosse began generating power for subscribers in March 2019 and a third project is expected to be built later during the year in Ashland. Once that project is complete, local gardens will be available to customers throughout our Wisconsin service territory. Similar to Renewable*Connect, the incremental program costs are covered through subscription fees so that non-participating customers do not pay extra to make the program available.

Customers also continue to install more on-site solar, with our Colorado customers increasingly choosing to install solar panels without incentives through Solar*Rewards®. Across all states, more than 7,600 solar systems were installed during 2018, adding 66 megawatts of additional on-site distributed solar. To reduce the impact of energy bills for customers struggling to make ends meet, we recently launched incentive options to test solar installations for income-qualified households in Colorado and Minnesota.

We offer the following renewable choice programs that reflect our company's commitment to meeting the clean energy interests of customers.

Program	Description	REC Attribution	MN	WI	ND	SD	CO	NM	TX	MI
Renewable*Connect	A flexible and affordable way to subscribe for up to 100% renewable energy	Participant	■	■			■			
Windsource	An easy, low risk way to subscribe to clean wind energy	Participant	■				■	■		■
Solar*Connect Community	Subscribe to a solar garden and get full rights to the solar claims, plus a bill credit for choosing solar energy	Participant		■				■*		
Solar*Rewards Community	Subscribe to third-party solar gardens and receive electric bill credit payments for solar energy produced	All Customers	■				■			
Solar*Rewards	Install your private on-site solar system and earn an incentive for transferring the RECs to Xcel Energy	All Customers	■				■	■**		
Net Metering	When you produce wind or solar energy through on-site equipment, you're able to retain RECs and sell any excess energy back to the grid	Participant	■	■	■		■	■	■	■

*Solar*Connect Community has been filed but not yet approved in New Mexico.

**New Mexico Solar*Rewards availability varies from year to year and is not currently available.

In addition to renewable choices, we started offering customers in Wisconsin a Certified Renewable Percentage as a way to let them claim the full benefit of our increasingly clean energy mix. We now retire Renewable Energy Credits (RECs) to cover the entire renewable energy portion of the electricity we deliver to customers in Wisconsin, beyond what we retire to meet Wisconsin's Renewable Portfolio Standard. Certified Renewable Percentage is not something customers enroll in or subscribe to but is a benefit they automatically receive. This enables customers to make renewable energy claims. For example, our commercial customers can claim the portion of renewable energy included in the Certified Renewable Percentage just by being an Xcel Energy customer.

We plan to propose the approach for regulatory approval in Colorado and Minnesota this year to begin offering customers the same benefit in these states.

Integrating Wind and Solar Power

The significant wind and solar resources on our systems have fundamentally changed the way we operate. With each increase in renewable capacity, we have improved system operations, enabling our ability to incrementally grow the use of wind and solar power and achieve new system records.

Some of our operational improvements for accommodating more wind and solar energy include:

- **Adding more flexible backup generation.** As we retire aging coal plants, we are replacing some of the energy with more carbon-friendly natural gas generation, which can more efficiently and cost-effectively ramp up or down to accommodate variable, renewable generation.
- **Cycling coal offline and reducing minimum generation levels.** Once considered infeasible, we are turning off coal units to accommodate more wind generation and are reducing the time that units need to be offline before than can be restarted. Cycling off coal units and then turning them back on is much more challenging than with a natural gas unit because of all the systems involved, but our Operations team has studied the issues and is working to cycle coal units more efficiently and cost effectively, helping to reduce fuel use and emissions.
- **Negotiating greater flexibility from our natural gas suppliers.** These agreements allow us to efficiently use our gas generation resources to balance variable renewable generation, helping to increase system reliability and lowering customer costs.
- **Investing in transmission.** We are improving and building new transmission facilities that can deliver more wind and solar energy to customers.
- **Using control equipment.** We use set-point controls for wind farms in combination with automatic generation control of thermal units that lets wind farms operate at peak levels while fossil-fuel production is reduced.
- **Establishing a 30-minute flexibility reserve.** We previously carried one megawatt of reserve capacity for every megawatt of wind generation as backup in case winds suddenly dropped off. As our wind portfolio grew, we studied the maximum amount of wind energy typically lost within 30 minutes and were able to reduce this reserve, dramatically decreasing costs associated with carrying large wind reserves while maintaining system reliability.
- **Adjusting planned maintenance.** We now plan transmission and plant maintenance outages around times of the year when wind and solar production is lowest.

Generally, we find that wind and solar are very compatible resources for meeting customer needs. Our renewable generation works together fairly consistently to operate on average across all hours of the day.

While solar energy is relatively simple to forecast, wind generation has been notoriously difficult because of its variability. Most weather forecasting models are designed to generate information about winds near ground level rather than at 200 to 300 feet, where turbine hubs are located. Also, landscape features such as hills and trees can reshape wind speeds and directions, causing turbulence in ways that can greatly influence the amount of energy produced.

To improve on this, we began working in 2009 on a multi-year research and development project with the National Center for Atmospheric Research (NCAR) and its affiliate company Global Weather Corp. (GWC). Today the WindWX system helps utilities around the globe including Xcel Energy to make better commitment and dispatch decisions. It uses real-time, turbine-level operating data and applies sophisticated algorithms to forecast the amount of wind power that will be produced. Forecasts for a 168-hour period are provided every 15 minutes across Xcel Energy's entire service territory — from the hills of western Minnesota to the plains of eastern Colorado and the Texas Panhandle.

Compliance with State Renewable Energy and Portfolio Standards

Xcel Energy is on pace to surpass established renewable energy requirements in the states we serve through at least 2030. New Mexico recently adopted the Energy Transition Act to set one of the most ambitious renewable portfolio standards in the nation. We are currently evaluating our compliance strategy with the increased targets that will be set by the law once it takes effect in June of 2019.

Renewable Energy Requirements in Xcel Energy States

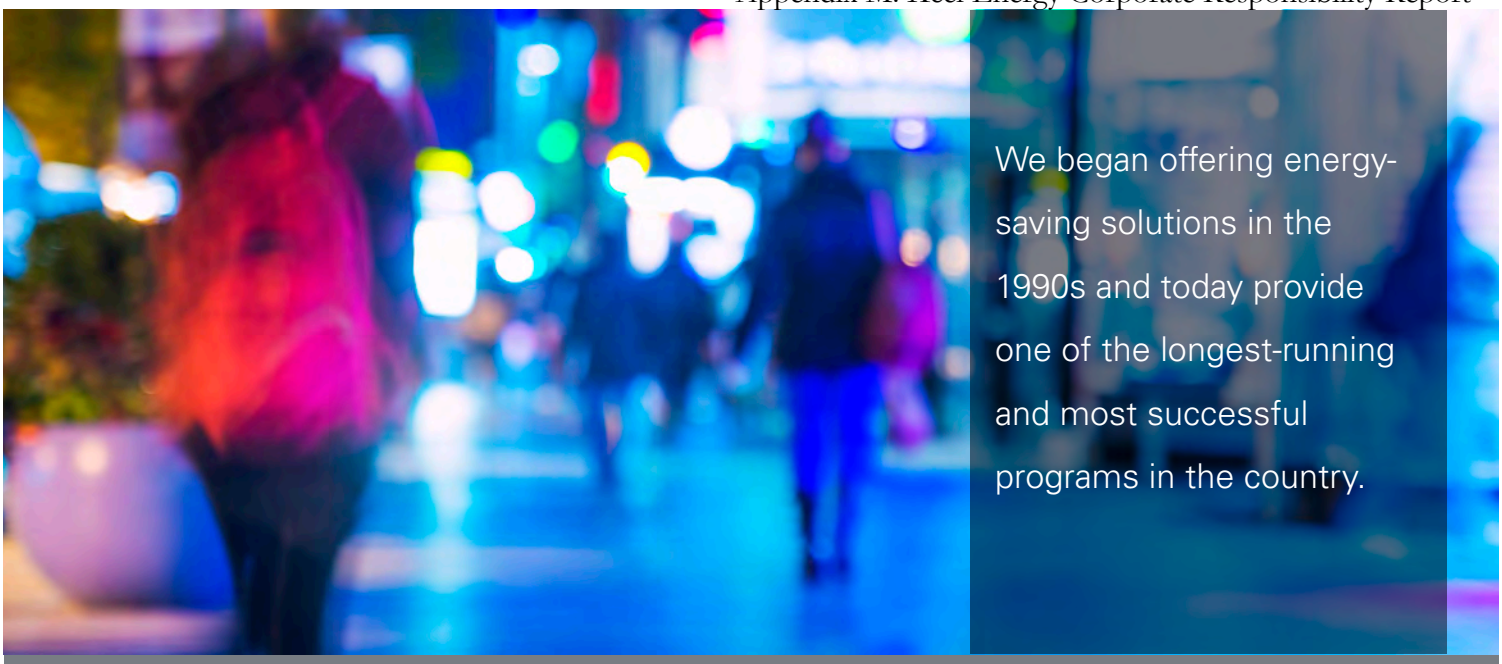
State	2018	Next Increase	Notes
Colorado Renewable Energy Standard	20%	30% by 2020	30% of retail sales by 2020, with 3% from distributed generation (DG), including at least 1.5% from retail net-metered DG resources and up to 1.5% from wholesale DG resources (defined as resources ≤30 megawatts located in Colorado that are not customer sited)
Michigan Renewable Portfolio Standard	10%	12.5% by 2019; 15% by 2021	Goal of 35% by 2025
Minnesota Renewable Portfolio Standard	25%	31.5% by 2020	30% of retail sales by 2020, with at least 24% from wind, plus 1.5% of retail sales from solar by 2020, with at least 10% from on-site solar 40kW or less
New Mexico Renewable Portfolio Standard	15%	20% by 2020	The New Mexico Energy Transition Act increases future goals of the RPS; in addition to the immediate goals, it sets a standard of 40% by 2025, 50% by 2030, 80% by 2040 and then 100% carbon-free electricity by 2045 Note: the Public Regulation Commission must consider the safe and reliable operations of the system and the prevention of unreasonable costs
North Dakota Renewable and Recycled Energy Objective		Voluntary	No RPS Requirement for North Dakota
South Dakota Renewable, Recycled and Conserved Energy Objective	10%	Voluntary	No RPS Requirement for South Dakota
Texas Renewable Generation Requirement	Statewide Goal	10,000 MW statewide by 2025 (goal achieved) & (non-wind goal: 500MW)	Xcel Energy's portion is approximately 3.3% of the statewide goal (the 3.3% is based on Xcel Energy Texas electric retail sales as a percentage of the total state electric retail sales)
Wisconsin Renewable Portfolio Standard	12.89%		

Renewable Energy Credits

A renewable energy certificate or credit (REC) is created for every megawatt-hour of renewable electricity generated (1 REC = 1 MWh). RECS provide a mechanism to commoditize renewable energy attributes and are tracked in national commission-approved REC tracking registries. RECs can be disaggregated or separated from the underlying renewable energy and sold separately. Typically, RECs are traded to companies looking to claim green energy or transferred to other utilities to reduce compliance costs.

Xcel Energy uses RECs to satisfy compliance with state renewable energy standards throughout our service territory. Our company carefully tracks its REC ownership and works to comply with the rules and best practices around renewable energy claims. Only parties that own and retire RECs can claim to use the renewable energy, according to the Federal Trade Commission's Green Guides. However, renewable energy separated from or without the associated REC can retain its value and be used for compliance with environmental regulations.

In 2018, we continued to look for ways to increase the value of the renewable energy on our systems through the sale of RECs. In several states, Xcel Energy has more renewable energy on its system than is needed for compliance with renewable energy standards. Based on market opportunities and the projected shelf life of RECs, we sold more than 3.7 million RECs in 2018, about 3 million less than in 2017. The renewable energy that generated these RECs came from Colorado, New Mexico, Texas and the Upper Midwest. Our customers benefit by sharing portions of these profits associated with the sales. REC sales make up a minor portion of our REC holdings.



Energy efficiency

Encouraging Efficient Energy Use

Our comprehensive portfolio of energy solutions meets the individual needs and preferences of customers and gives everyone an opportunity participate — from large industrials to small businesses and customers living on fixed incomes.

Customers rely on the energy we provide for their comfort, security and convenience, but increasingly they want more control and new options for managing and using energy. We are paying attention to the market, listening to our customers and responding with new and improved solutions.

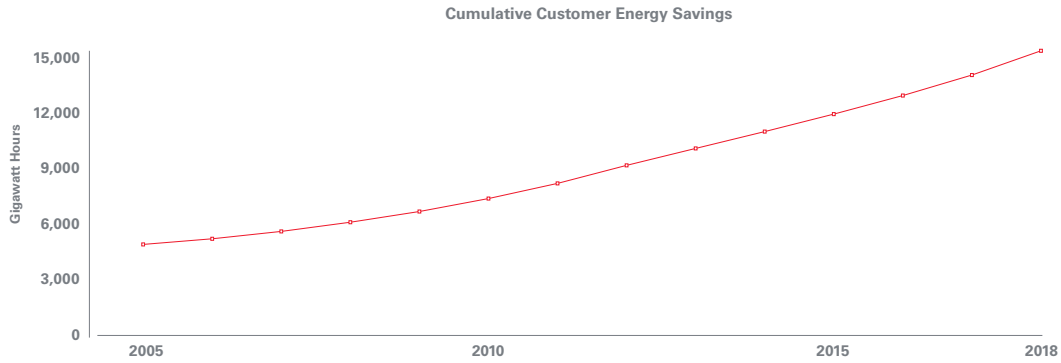
We continuously evaluate emerging technologies and program models, looking for opportunities to expand our portfolio of energy solutions and anticipate evolving customer needs and interests. Beyond our customer offerings, we continue to demonstrate leadership by incorporating energy efficient technologies and practices at Xcel Energy office buildings and service centers.

2018 Results

- Five of Xcel Energy's energy efficiency programs are recognized as being among the country's best, according to the American Council for an Energy-Efficient Economy (ACEEE). The following programs received the organization's Exemplary Program Award in early 2019: the Low-Income Program and Energy Design Assistance in Colorado, Home Energy Squad and One-Stop Efficiency Shop in Minnesota, and Partners in Energy in both Colorado and Minnesota.
- Our customers completed nearly 3.5 million electric and 1.4 million natural gas efficiency projects and received $141million in rebates through our conservation programs. We had more than 42,000 customers participate in our load management or demand response programs.

- We launched five new demand response programs, which helped participating customers save money and provided flexibility in how we manage the power grid. Under the programs, customers reduce or shift their energy use during peak periods, helping balance the supply and demand of electricity. We have around 25 new programs set to launch between 2018 and 2021 and have installed a new system to track demand response use and effectiveness.
- Altogether, customers saved about 1,240 gigawatt hours of electricity for the year, equivalent to powering 160,000 average homes, and 1.6 million dekatherms of natural gas, enough to fuel 20,000 average homes. The annual energy savings through efficiency measures was enough to avoid about 780,000 tons of carbon emissions, equivalent to the annual carbon emissions from approximately 150,000 cars.
- Some of the states we serve provide incentives for achieving energy efficiency goals. Thanks to strong program performance, we earned more than $41 million in incentives, exceeding our expectations.
- In early spring 2019, we hosted our annual Energy Expo for Colorado industrial, commercial and small-business customers. It featured teams of energy experts from Xcel Energy and outside organizations providing energy-saving ideas and opportunities for rebates and energy efficiency study funding. During the event, 13 businesses were recognized for outstanding efforts to save energy. These companies greatly lowered energy costs and reduced their impact on the environment. Altogether, they saved more than 33 million kilowatt hours of electricity in a 12-month period.
- Xcel Energy's Education and Outreach program promotes and encourages customer participation in our energy efficiency and renewable choice programs. During the year, we successfully expanded our efforts in Colorado, Minnesota and New Mexico. We reached more than 4.2 million people and generated over 19,800 targeted customer leads and 5,900 direct program sign-ups through event participation and community sponsorships. Some of our more notable partners include the Como Zoo in Minnesota, Denver Botanic Gardens, and sports teams — the Saint Paul Saints and Denver Outlaws.

Since we began consistently tracking results in 1992, we estimate that the energy savings through our efficiency programs has avoided the need for 21 average-size power plants.



State-by-State Efficiency Programs and Performance

Xcel Energy's portfolio of over 150 electric and natural gas conservation programs continues to experience strong customer engagement and growth. We continued to help our customers achieve significant energy savings in 2018, meeting and exceeding savings goals in several key states. The following is a summary by state of overall performance and program offerings.

Minnesota

2018 Approved Savings Goals of 433,694,480 kWh and 769,720 Dth	
Electric Projects	1,920,207
Natural Gas Projects	765,805
Total Spending	$122,958,724
Electric Savings	680,448,447 kWh
Natural Gas Savings	913,240 Dth

In Minnesota, we offer residential programs that range from prescriptive rebates to in-home services providing energy-efficient materials and labor for installation. Consumer education is included with most of the residential programs to increase conservation awareness and encourage energy-wise choices and behavior in the home. We also offer services and products to help income-qualified customers reduce their energy use and ultimately lower their bills.

The business segment includes electric and natural gas commercial, industrial and small business customers. We offer a variety of programs that encourage business customers to save energy, lower their energy bills, reduce peak demand and minimize environmental impacts. The portfolio has three primary components, including prescriptive products focused on common equipment, custom products to encourage savings from unique situations, and study and educational products that help customers identify energy efficiency opportunities.

North Dakota

Electric Projects	149
Natural Gas Projects	880
Total Spending	$257,670
Electric Savings	16,426 kWh
Natural Gas Savings	12,697 Dth

We provide savings opportunities for North Dakota business customers through load management programs, as well as residential natural gas rebate programs and home energy audits.

South Dakota

2018 Approved Savings Goal of 5,761,199 kWh	
Electric Projects	62,953
Total Spending	$775,604
Electric Savings	6,057,290 kWh

Our energy efficiency portfolio for South Dakota customers is a mix of electric programs designed to encourage both residential and business customers to save energy and lower their energy bills in a variety of ways. We offer programs for lighting, load management and educational outreach for business and residential customers and continue to work with trade partners to promote our programs.

Wisconsin

Electric Projects	153,135
Natural Gas Projects	152,758
Total Spending	$9,872,298
Electric Savings	119,139,835 kWh
Natural Gas Savings	98,169 Dth

In Wisconsin, Xcel Energy participates in a statewide program called Focus on Energy that provides incentives to eligible residents and businesses for installing cost-effective energy efficiency and renewable energy projects. We retain a portion of the approved annual funding for our voluntary customer programs and to promote the Focus on Energy programs. We also use the funds for general conservation activities, advertising and energy efficiency education for residential customers, commercial customers and trade allies in our service territory.

Michigan

Electric Projects	15,634
Natural Gas Projects	321
Total Spending	$384,663
Electric Savings	1,292,727 kWh
Natural Gas Savings	6,170 Dth

We participate in a statewide program in Michigan called Efficiency United that educates residential and commercial customers about energy efficiency and offers cost-effective solutions and rebates for reducing energy use.

Colorado

2018 Goals/Targets of 400 GWh and 573,136 Dth	
Electric Projects	793,208
Natural Gas Projects	449,006
Total Spending	$107,385,072
Electric Savings	453,894,496 kWh
Natural Gas Savings	604,928 Dth

Our Colorado residential energy efficiency programs focus on cost-effective, direct impact products that target household appliances, HVAC and lighting. This effort is supplemented with educational services intended to further increase customer understanding and interest in conservation and energy efficiency. We also offer income-qualified customers products to analyze natural gas and electric consumption, and provide products, services and education designed to help lower energy bills.

Our business program — for commercial and industrial customers of all sizes — offers a broad portfolio of demand side management products designed to meet the needs of this varied segment. The portfolio has three primary components, including prescriptive products focused on common equipment, custom products to encourage savings from unique situations, and study and educational products that help customers identify energy efficiency opportunities.

New Mexico

Electric Projects	371,298
Total Spending	$10,685,496
Electric Savings	51,698,426 kWh

We offer a broad portfolio of programs to meet the needs of business, residential and low-income customers in our eastern New Mexico service territory.

Texas

Electric Projects	145,992
Total Spending	$3,610,230
Electric Savings	20,524,107 kWh

We offer our Texas customers energy efficiency programs through Standard Offer Programs and third-party Market Transformation programs. These programs are provided to residential, low-income, commercial and industrial customers.

Conservation at Xcel Energy Facilities

Our building management practices support our commitment to the environment and the communities we serve. We own or lease more than 150 office building and service centers throughout our eight-state territory and strive to set an example with conservation. Similar to how we encourage customers to use energy more efficiently in their homes and businesses, we look for ways to save energy and water in our own facilities, especially when those opportunities reduce our costs and conserve resources.

We also go beyond conservation to incorporate a number of environmentally sound practices into our daily building management, including steps that ensure indoor air and water quality, green cleaning and the use of GREENGUARD Certified products and materials.

We proactively began managing our facilities to reduce environmental impact in 2008, and by the end of 2018, have accomplished the following:

- Saving more than 8 million kilowatt hours
- Conserving more than 173,600 therms of natural gas
- Reducing water usage by 4.7 million gallons

Through our energy management initiative, we plan to continue trying to identify and implement projects that reduce energy use and costs at our facilities while helping to reduce overall maintenance needs. Projects will consist of individual, standalone opportunities, as well as efforts to support and improve new construction, remodeling and HVAC replacement projects that are planned and approved. To do this, we review past facility energy audits with the company's annual capital budget to identify energy improvement opportunities to support.

LEED Certified Facilities

Xcel Energy continues to seek LEED (Leadership in Energy and Environmental Design) certification for our facilities. We currently have 15 facilities that are LEED certified throughout the eight states where we operate. LEED is a U.S. Green Building Council certification program that recognizes sustainable building strategies and practices. To receive LEED certification, building projects satisfy prerequisites and earn points to achieve different levels of certification. LEED certification has four levels — Certified, Silver, Gold and Platinum — based on achievement in five areas: sustainable site development, water savings, energy efficiency, materials selection and indoor environment quality.

Company and workplace

Governance, ethics and compliance

Corporate compliance and business conduct

For decades we have fostered a culture of compliance and ethical business conduct, striving to earn and maintain the trust of our stakeholders.

For more than 100 years, we have had the privilege of serving our customers and doing so with honesty and integrity. Because trust is so essential to our ongoing success, it is included in our corporate vision to be the preferred and trusted provider of the energy our customers need. To help deliver on this vision, we hold our employees, contractors and board of directors to the highest ethical standards and ensure their decisions are consistent with our values.

Every day we deliver safe, clean, reliable and affordable energy while holding ourselves accountable and acting responsibly. Through our commitment to doing what is right, we have established a reputation that our employees can be proud of and gives customers confidence in doing business with us.

2018 Results

- We revised our corporate values, putting new focus on who we are as a company today and who we want to be in the future. Through conversations across the organization, we asked ourselves what values will guide us for the years to come as we continue to evolve. Employees have responded positively to our renewed values of Connected, Committed, Safe and Trustworthy.
- We updated policy content in response to new or changing regulations and business practices. An example is our new, stand-alone anti-retaliation policy. While our Code of Conduct has always prohibited retaliation and protected employees who report concerns, we created a dedicated anti-retaliation policy to increase visibility of the company's expectations.

- We focused on educating leaders on how to respond to employee concerns and prevent, recognize and report retaliation. We held in-person compliance and ethics training, created a micro-learning training module and launched an e-learning course titled Compliance for Leaders.
- We completed a system refresh of Xcel Energy's allegation of wrongdoing case management system. This initiative included streamlining the hotline phone- and online-reporting intake form to make it easier for employees to report concerns, as well as simplifying the process of recording and monitoring progress on the investigations. These improvements drive consistency in reporting and enhance the employee experience.

Ethical Foundation: Code of Conduct

Our Code of Conduct serves as the foundation for our Corporate Compliance and Business Conduct program. It guides everything we do — how we work together, make business decisions and interact with stakeholders. Our Code of Conduct also provides guidance for handling difficult judgement calls and reporting concerns.

The board of directors reviews and approves the Code of Conduct annually, ensuring top-level ownership for this foundational resource.

Employees at all levels, as well as contract workers and our board of directors, are expected to apply the Code of Conduct to their work with Xcel Energy. Code of Conduct training occurs annually and included in the training course is a statement of commitment. While contract workers are not required to take Code of Conduct training, they are required to perform services in accordance with the Code of Conduct as specified in the terms of their agreements with Xcel Energy.

Corporate Compliance and Business Conduct Program

The focus of Xcel Energy's Corporate Compliance and Business Conduct program is to:

Do What's Right: Report What *Seems* Wrong.

Sound Governance Practices

Xcel Energy's Board of Directors has overall authority for the Corporate Compliance and Business Conduct program, with key elements of oversight delegated to the Audit and Governance, Compensation and Nominating committees. Our Corporate Compliance and Business Conduct Council is comprised of leaders from across the company and ensures engagement with all employees.

The company's CEO sets a strong tone at the top and supports that tone in many ways including championing the values refresh and highlighting the company's commitment to compliance on webcasts and in-person at various team meetings. The chief ethics and compliance officer reports to the CEO, and also oversees the company strategy and corporate governance functions, enabling her to effectively drive company culture and values. The integration of these activities and responsibilities ensures that compliance is part of how we make decisions across the company.

Policies, Training and Communications

Company policies, training and communications help employees understand expectations in order to make good decisions every day. Information about policies and expectations are shared through multiple channels and in multiple ways to ensure that they are a regular part of all employees' work experience.

Employees are responsible for knowing and following not only the Code of Conduct but also multiple other corporate policies associated with Corporate Compliance and Business Conduct. Training courses include content from corporate policies and other information that demonstrate how our values guide the way we do business. Employees use training information to ensure their actions protect and enhance the company's brand and reputation by working safely and effectively and complying with the many policies, laws, regulations and expectations governing our work.

Regular, consistent communications are designed to help employees do what's right. We use a variety of channels to reach employees across teams, such as emails, posters, videos, intranet news articles and in person discussions.

Issues, Investigations and Actions

When things don't seem right, employees are encouraged to discuss concerns with their leaders. We know reporting a potential issue can be difficult, so we offer multiple reporting options that include contacting:

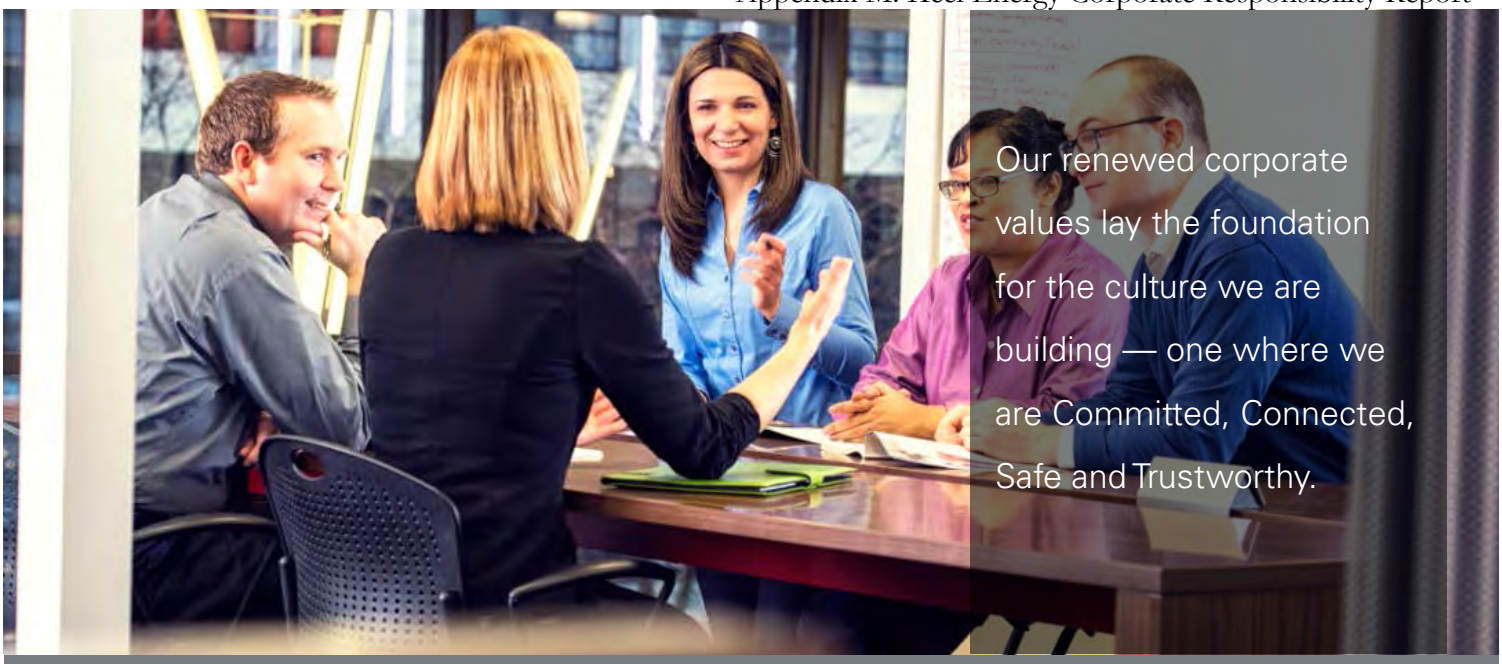
- Equal Employment Opportunity, Employee Relations or Workforce Relations
- The employee's next level of management
- The Compliance Hotline, available 24 hours a day and with the option to remain anonymous
- The Corporate Compliance and Business Conduct Office
- Legal Services
- The Xcel Energy Board of Directors

Employees working at our nuclear generating plants have additional reporting options that include completing a Nuclear Corrective Action Request form, reporting issues to the Employee Concerns program or contacting the Nuclear Regulatory Commission.

Our Compliance Hotline also offers employees the opportunity to ask questions about decisions they are unsure about.

As we follow up on reports, we conduct effective and timely investigations, take appropriate action and ensure employees are safe from retaliation. The Investigations Governance Committee oversees the investigation process and is comprised of the chief ethics and compliance officer, general counsel, chief financial officer and chief human resources officer.

When concerns are reported through the Compliance Hotline, the Corporate Compliance and Business Conduct Office assigns them to the appropriate business function to investigate based on allegation type. Business functions include Equal Employment Opportunity and Employee Relations, Workforce Relations, Legal, Security or Audit. These business functions also receive and investigate concerns reported through other channels. All reports are tracked and processed through a case management system that provides the company with a comprehensive view of allegations.



Workforce development

Our people and culture

At Xcel Energy, our business and workforce are changing while customer expectations are rising — a dynamic that is driving us to become more innovative, competitive and customer focused.

Our workforce strategy begins with a mission to proactively attract, retain and develop the highest quality talent. We take a proactive approach to workforce planning and are identifying the skills we need to prepare and meet our future energy objectives, aligning our talent strategies to build diverse pipelines and identifying opportunities to retrain or develop our workforce.

We know our people are our greatest strength. That is why once employees are part of our team, we offer extensive training and engagement opportunities to develop their skills and talents and help them grow professionally, in addition to recognizing their achievements. We are also improving our leadership development programs, tools and resources to help ensure our leaders are effective in our changing environment. Through these efforts, our objective is to develop inspirational and courageous leaders that hold employees accountable for achieving results.

2018 Results

- More than 96% of employees participating in Connect 4 Performance met with their leaders for Quarterly Connections to discuss job performance, professional development and alignment with company goals and priorities.
- Internal candidates successfully filled 41% of our 2,318 job postings, and of employees newly hired to the company, 56% came from within the states we serve and nearly 24% had ethnically diverse backgrounds.

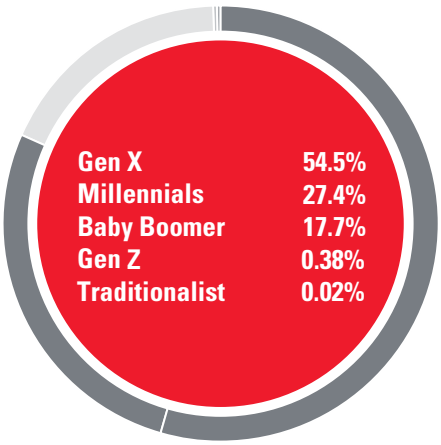
- Xcel Energy was named a Top Veteran-friendly Company by U.S. Veteran's Magazine for the fifth consecutive year, a Best for Vets employer by Military Times for the fourth consecutive year, and a Top-10 Military Friendly Employer by GI Jobs for the ninth consecutive year. We are included in Military Times' Best for Vets Index, and are honored to be a Most Valuable Employer for Military, according to Recruit Military. More than 10% of our new hires were veterans.
- For the third consecutive year, we received a perfect score on the Human Rights Campaign Corporate Equality Index and the designation as one of the Best Places to Work for LGBTQ Equality.
- Through a collaborative process that included feedback from employees throughout the organization, we renewed and streamlined our corporate values to reflect our core beliefs — who we are, how we conduct our business and the importance of our customers. We are Committed, Connected, Safe and Trustworthy.

Workforce Profile

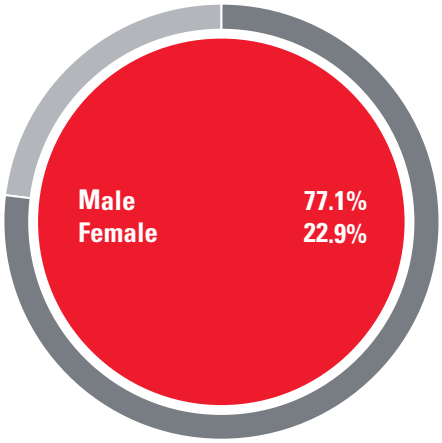
Bargaining		Non-bargaining		
43% Bargaining	5% Temporary Craft	2% Temporary	38% Nonmanagement Professional	12% Management

As of year-end 2018, Xcel Energy had 11,691 full-time, part-time and temporary employees.

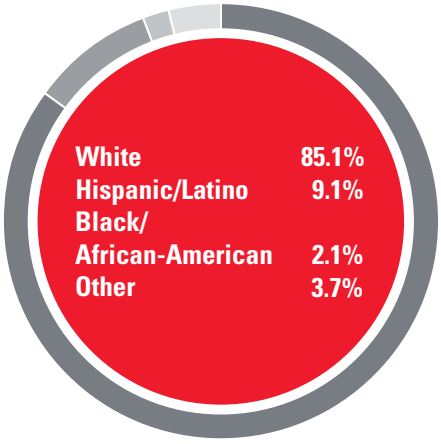
Generational Age



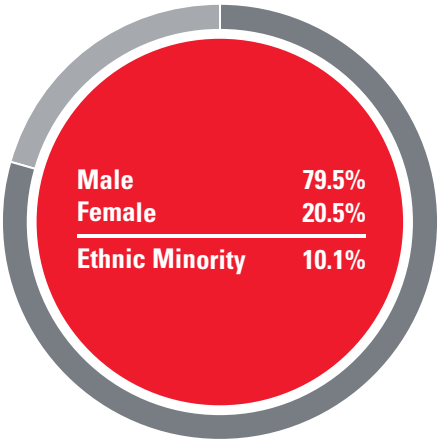
Gender



Ethnicity



Management Gender and Ethnicity



The average employee turnover in 2018 was 9.9%. About 29.7% of turnover was the result of retirements, about 56.1% were resignations and the remaining 14.2% includes turnover for other reasons, such as unsatisfactory performance, misconduct, severance or death.

Our projections show that 27.9% of our workforce will be eligible for retirement over the next five years and 41% over the next 10 years. However, we do not expect all employees to retire once they become eligible.

Workforce Planning and Analytics

Our strategic workforce planning models and process support leaders in using the opportunities that arise as a result of changes in our business objectives, including the workers required to complete budgeted work and turnover. By leveraging data and analytics, we are able to more accurately determine what the organization will need in terms of size and skill sets to achieve its objectives. The strategic workforce plan supports a more intentional approach to deploying solutions that will address our changing workforce.

In conjunction with this effort, we provide a Human Capital Report that helps leaders make data-based decisions. It is a dashboard that includes standard measures related to employee cost, performance management, and headcount and attrition trends. This information, combined with consultation with business partners, informs our leaders about their current workforce and predictive and statistical analysis provides insights into future impacts.

Attracting Top Talent

To ensure a steady stream of qualified candidates for Xcel Energy's available jobs, we proactively engage with community and educational organizations to prepare a future workforce. We are focused on helping military veterans make the transition to civilian jobs through targeted recruitment and participation in the Hiring our Heroes program. To ensure we can best support our customers' needs, we are committed to having a diverse workforce that reflects the communities we serve.

Some of our targeted recruitment activities include:

Educational Relationships

We work with a number of colleges, universities and technical schools to provide an avenue to educate students on the opportunities for stable, well-paid jobs with energy providers like Xcel Energy. As a member of the Center for Energy Workforce Development (CEWD), we also help develop training and curriculum that prepares students for skilled jobs in the energy industry. Through our partnership with CEWD, we implemented the Legacy I-3 program for high school students in the Twin Cities to build a pipeline of diverse candidates.

Internships

Through internships we ensure a pipeline for our future workforce needs. We hired 26 college interns into full-time positions with the company in 2018. We work with high schools throughout our Texas and New Mexico service areas, where we have the greatest needs. In Colorado, we have four programs in partnership with Denver Public Schools and Jefferson County high schools. In Minnesota, we continue our partnership with Step-Up Achieve and Right Track to hire high school summer interns. Through these programs, we had 60 high school interns in 2018.

Targeted Job Fairs

We seek out employment events that help us successfully identify and hire qualified employees who are customer focused, curious and innovative. We maintain relationships with several schools and local organizations within our service territory that hold job fairs for diverse populations. Partnerships like this allow us to reach prospective employees to continuously improve our candidate pool.

Search Engines

Xcel Energy markets its jobs on several key sites, including Indeed, LinkedIn and other social media platforms. In partnership with Professional Diversity Network and other industry and skill-specific boards, we target diverse, local talent and individuals that have specialized skills. We also work with local, community-based organizations to reach candidates throughout our service areas, reducing the need for candidate relocation and supporting our local economies.

Military and Veteran Outreach

We remain focused on strengthening our strategic partnerships with military veteran organizations and engaging in activities that maintain our visibility as a preferred employer for veterans. Through military-specific marketing and communications efforts and participation in more than 35 job fairs that specifically target military veterans throughout our service territory, our commitment to hiring veterans and active duty reservists remains strong.

Diversity Outreach

Through our partnerships with workforce centers in Minnesota, Colorado, Texas and New Mexico, Local Job Network and Diversity Minnesota, we are able to reach diverse job seekers in the places where they live and work. We also engage with diverse student groups such as National Society of Black Engineers, Society of Women Engineers, Society of Hispanic Professional Engineers and Society of Asian Scientists and Engineers to attract diverse entry-level employees.

Diversity and Inclusion

We believe that a diverse and inclusive workforce makes our company stronger. Our commitment to diversity and inclusion goes beyond human resource policies and practices — it is an integral part of who we are, how we operate and how we see our future.

Our inclusive work culture embraces all employees and provides them with equal access to employment opportunities and development. To us, diversity is more than ethnicity, gender, age, race, national origin, disability, religion and sexual orientation. It includes differences in thought processes, educational backgrounds, work experiences, personalities, lifestyles and cultural backgrounds.

Each Xcel Energy employee is empowered to make a difference when it comes to creating an inclusive environment. We encourage our employees to remember that:

Diversity Exists: Inclusion is My Responsibility.

Diversity and Inclusion Education

Xcel Energy's commitment to diversity and inclusion is instilled in employees from their first day on the job, as part of our new employee orientation program. Employees receive ongoing education in these areas, and in 2018, 813 employees and leaders throughout our service territory participated in a new half-day diversity and inclusion education session. The classes are designed to provide knowledge, insight and skills to manage diverse teams and create an inclusive culture. The company goal is to have 100% of employees through the program within three years.

Business Resource Groups and the Council for Diversity and Inclusion

Our 11 Business Resource Groups give Xcel Energy employees an inclusive and supportive venue to unite for personal and professional growth. They offer opportunities for cultural exchange and community outreach and helping solve business challenges. Additionally, through the Council for Diversity and Inclusion, leaders of our Business Resource Groups collaborate with leaders from our business areas to help address key challenges and achieve goals.

- **ECN (Employee Connection Network):** Connects new and existing employees and helps broaden all employees' understanding of Xcel Energy through networking opportunities, meet ups and community service events.
- **GCEEE (General Counsel Employee Excellence and Equality Committee):** Aids the general counsel in fostering a spirit of inclusiveness throughout the company.
- **GenNext:** Aims to support employees through employee education, collaboration and development.
- **GROW:** Identifies and implements innovative ideas and strategies for recruiting, developing, promoting and retaining women in non-traditional work roles in our Energy Supply business area.
- **MOVE (Military Ombudsmen for Veterans and Employees):** Sustains awareness on issues of interest to veterans and active military employees in our workforce and programs and policies that support the welfare of veterans and their families.
- **SAGE (Supportive Association for Gay/Lesbian/Bisexual/Transgender Employees):** Works to help the company become and remain a leader in this area of workforce diversity by addressing issues relating to sexual orientation and gender identification.
- **SOURCE (Strategic Organization Utilizing Resources for Career Enhancement):** Promotes career development, continued education, training and cultural awareness with a focus on African Americans.
- **Tribal Wind:** Supports diverse workforce initiatives and the Native American population through business initiatives such as recruiting, retention, professional development and cultural awareness.
- **WIN (Women's Interest Network):** Focuses on issues of interest to women, such as professional development and work/life balance.
- **!Xcelente¡:** Increases visibility of Latino employees within the company and community while also promoting professional development and sharing Latino culture through awareness, inclusion and celebration.

- **XE WiN (Women in Nuclear):** Explores and develops programs that help all employees working within our nuclear organization to expand their leadership skills, network and create positive visibility for the nuclear industry within the communities we serve.

Performance Management

Last year was the third year for Connect 4 Performance, our performance management approach for non-bargaining employees who make up over half of our workforce. Connect 4 Performance enables employees to align their individual goals with the priorities of Xcel Energy through simple, meaningful and frequent conversations with their leaders. Throughout the year, employees and leaders work together to identify opportunities that support employee professional development while helping achieve the company's strategic priorities. Employees are encouraged to record their development goals and regularly update and discuss progress and ideas with their leaders.

Employee Engagement

After pausing from our traditional approach to measuring engagement through an annual survey, Xcel Energy spent 2018 developing a comprehensive plan to measure our employee engagement and sentiment. In 2019, we are introducing a new platform that allows employees to provide feedback digitally giving leaders real-time results. This new approach will provide us the flexibility to gather employee feedback at different career points and conduct pulse surveys on engagement.

We help employees stay engaged through a number of channels, including regular webcasts with our senior leadership team, an intranet site that is updated daily, a regular company news magazine for employees and retirees, rewards and recognition programs, company-sponsored volunteer opportunities and our annual Day of Service.

Employees are continuously encouraged to offer feedback to Xcel Energy leadership through a variety of methods. They can submit anonymous comments and questions during regular leadership webcasts and face-to-face meetings, and respond to blogs and articles that our leaders publish throughout the year.

Workforce Relations

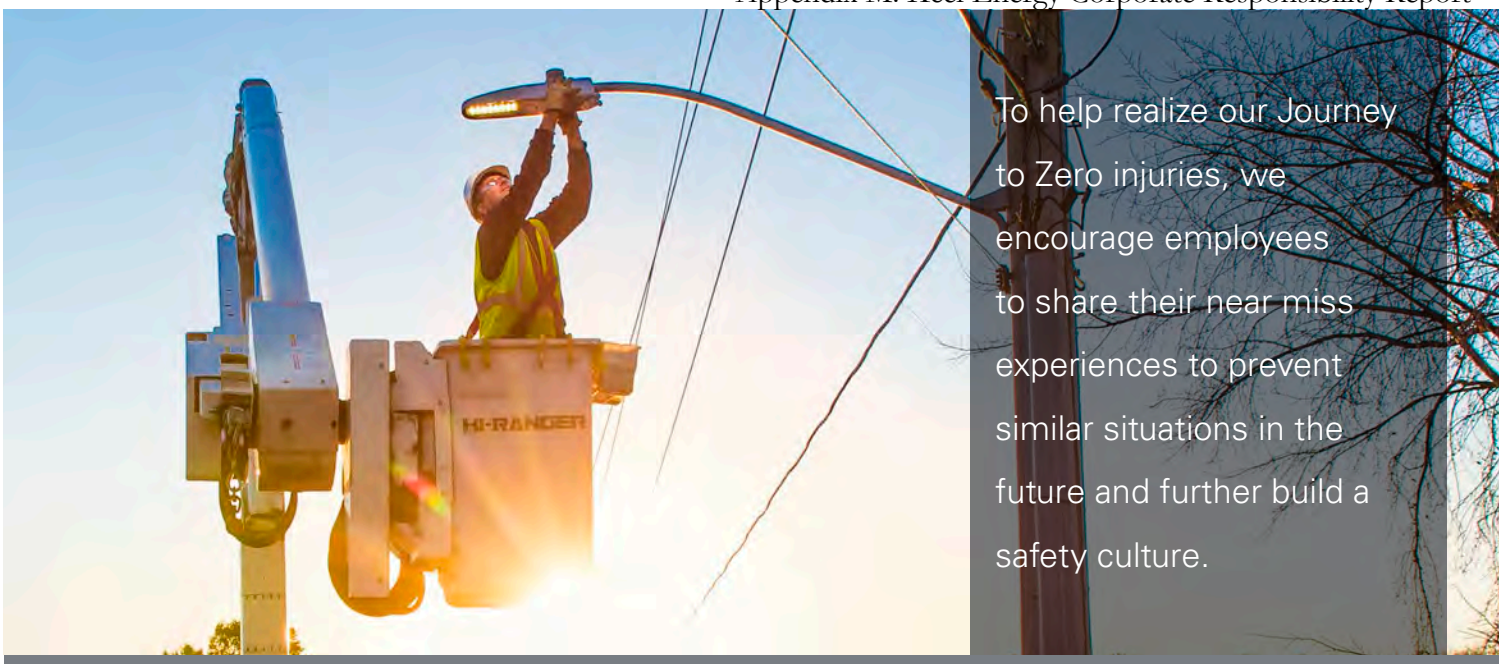
Xcel Energy is committed to providing all employees with a safe, rewarding workplace that values their contributions and ensures fair treatment. We respect our employees' right to organize if desired, and approximately half of our workforce is currently represented by unions.

While each collective bargaining agreement is negotiated with a specific local union, we include equal opportunity clauses in all our bargaining contracts. We also operate in compliance with the policies and regulations established by the National Labor Relations Board, the statutes of the National Labor Relations Act and the guidance of the federal Department of Labor.

Xcel Energy recognizes that all parties benefit by coming together to achieve mutual goals, so we meet frequently with our unions to discuss new and ongoing issues. Employee safety is a mutual focus for both bargaining units and the company. Bargaining unit employees fully support and participate in the company's safety advisory councils, committees, training and other programs.

Interim bargaining has been used for the past 18 years to improve union relations and promote collaboration on business challenges that impact our operations and workforce. We also hold regular meetings between management and labor unions to address grievances with the goal of resolving issues between the parties.

In early 2018, Xcel Energy (Public Service of Colorado) reached an agreement with the International Brotherhood of Electrical Workers (IBEW), Local 111 the Union representing our employees in Colorado.



To help realize our Journey to Zero injuries, we encourage employees to share their near miss experiences to prevent similar situations in the future and further build a safety culture.

Employee safety

Our journey to zero

When we refreshed our corporate values in 2018 to reflect our core beliefs, there was never a doubt that staying safe would remain a top priority.

Given the nature of our business, our employees face numerous hazards while performing their jobs. That is why we continue to instill a culture that values safety through the work of our safety committees, company policies, and training and ongoing awareness campaigns.

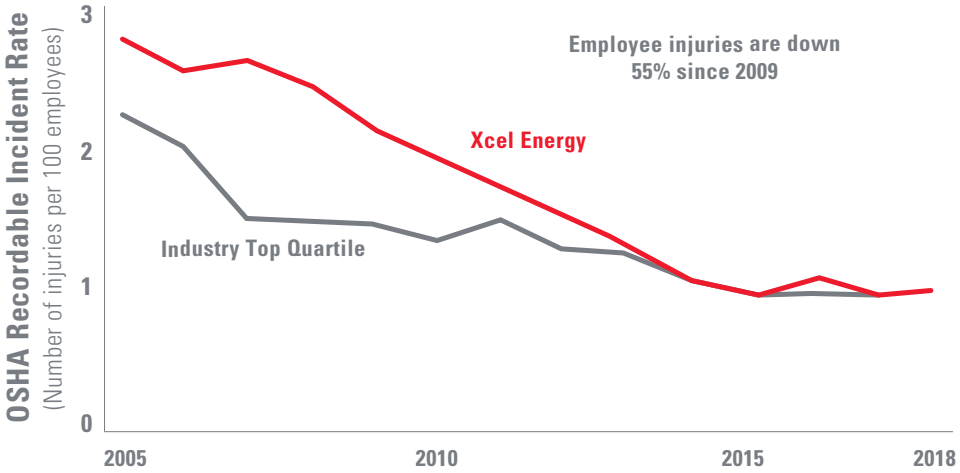
Our Journey to Zero is not just a slogan or program but is a commitment that all employees will return home from work injury free every day. It is about building a safer work environment by putting safety at the forefront of everything we do. Starting with top leadership, we continue to actively demonstrate support for safety throughout the organization. We strive to advance a safety culture through strategic behavioral safety programs and initiatives that encourage employees to take personal responsibility for their safety and the safety of others.

2018 Results

- Our employee safety performance ranks in the top-quartile for our industry. We have reduced OSHA recordable injuries by 55% and injuries classified as Days Away, Restricted and Transferred by 59% since embarking on our Journey to Zero.
- All contract employees receive safety training from their employers as a requirement of working with Xcel Energy. Plus, job briefings and job-site safety reviews occur daily. The total safety incident rate for contract workers in 2018 was down by almost 30%, even though the number of hours that contractors worked nearly doubled.
- We conducted Safety Leadership Training for all employees who are most at risk because they work directly with the delivery of electricity and natural gas.

- We continued to encourage employees to share their safety experiences and to learn from one another. Through a special campaign, we increased our near-miss sharing by 150% over 2017.
- The American Gas Association recognized our annual performance with the 2018 AGA Safety Achievement Award for excellence in employee safety.

Our Journey to Zero commitment entered into its ninth year in 2018 and continued to make significant progress in keeping employees safe. Although, as the name of this effort implies, we won't be satisfied until 100% of employees go home injury free.



Managing Employee Safety

Xcel Energy has 21 corporate safety policies in place to address occupational safety and health issues. These policies apply to all company bargaining and non-bargaining unit employees, as well as contractors. Our policies cover a wide range of topics — from working in confined and enclosed spaces to preparing for and responding to emergency situations.

As part of our corporate values, and to protect our employees and the public, working safely is the first consideration while planning or performing work. It is the role of Xcel Energy management to foster, develop, implement and provide training and communication about safety programs that will help reduce occupational injuries and illnesses at work. We expect employees to report unsafe acts, behaviors or conditions to management in a timely manner so that we may address these safety concerns. Any retaliation against an employee who, in good faith, reports a safety violation or suspected violation is strictly prohibited. All employees are empowered to stop work if they see unsafe practices

Our corporate safety organization manages implementation of regulatory compliance, provides technical consultation to business areas, tracks and communicates the company's safety performance, and fosters our safety philosophy and core value. The vice president of Safety and Workforce Relations leads this organization and reports to the chief human resources officer, who reports directly to the president, chairman and CEO. Xcel Energy's Operations, Nuclear, Environmental and Safety committee for the board of directors oversees the company's safety strategy and performance.

There are three key components to our safety and health culture that include:

- **Communication:** Within each business area, we verify that OSHA-required written programs are current and maintained at our facilities. Employees must be thoroughly briefed on site-specific hazards and protective measures prior to starting any job at an Xcel Energy operating facility or on electric and natural gas transmission and distribution lines and equipment. Finally, we establish a system of hazard analysis, which includes hazard identification and control in each business area, and we communicate this system to all affected employees.
- **Safety Committees:** Our safety committees are organized and represented by bargaining unit and non-bargaining unit employees and management. The expectations for these committees are outlined by management and periodically audited to track progress and effectiveness. Managers in each business area provide support for safety committee findings and recommendations that align with our corporate values.
- **Training:** Each business area and Corporate Safety develop training plans annually to include OSHA-required training and required elements of our Corporate Safety and Industrial Hygiene programs. We maintain thorough records of all training, including recording the names and dates of employees who complete required safety training.

We provide effective safety and health communications in various formats, including verbal instructions, written documents and posters, safety committee meetings and multimedia presentations, such as video and computer-based training. Through these various media, all employees have access to required safety and health training, policies, programs and safety manuals, as well as federal or state required communications. All Xcel Energy employees are expected to actively participate in the company's safety and health training and communications program.

Safety Initiatives

We continued a number of important safety initiatives in 2018, while also launching new initiatives to help keep employees safe.

24/7 Safety

Our 24/7 Safety campaigns focus on maintaining a safety mindset around the clock, helping employees to be safe both on and off the job. The 2018 campaign focused on intervening when you see something unsafe and some of the common household and public hazards to watch out for.

Ergonomics

Musculoskeletal Disorders (MSDs or strains and sprains and cumulative trauma disorders) are the leading type of injury at Xcel Energy, with sprains and strains representing more than 41% of our injuries. Several ergonomics training modules were initiated in 2018 to help improve this, including the Eyes on Ergo training module, Ergo Tips pocket guides and videos, prevention exercises and a Five-week Workplace Athlete Challenge.

Near Miss Sharing

Sharing near misses with coworkers provides a learning opportunity that can prevent similar situations in the future. To encourage employees to share their stories, we do not pursue discipline for employees who report near misses, and we carried out a campaign in 2018 that included video testimonials, posters and articles.

Safety Blitzes

After recognizing certain injury trends, company leaders set out to connect with employees to hear their views and suggestions about safety. Three safety blitzes were held in 2018 and a commitment was made by leaders to spend more time visiting with employees in 2019, as well.

Safety Leadership Training

To help reduce serious life-changing incidents, the Safety Leadership Training program was conducted in 2018 for all at-risk employees. The program was designed to transform how employees view their role in safety because everyone is a leader when it comes to safety.

Safety Promise

Xcel Energy's Safety department hosted a series of events in 2018 offering employees' families an opportunity to ask their loved ones to work safely on camera. The employees were then given the opportunity to make a safety promise on camera. These requests and promises were shared in various formats, encouraging everyone to make a personal commitment to their safety and the safety of those around them.

Slips, Trips and Falls

Slips, trips and falls are avoidable, yet each year they make up a significant number of Xcel Energy's OSHA recordable injuries. We enhanced our Slips, Trips and Falls Toolkit in 2018 to include even more videos, training and guides detailing strategies for these incidents and minimizing the chance of injury when falling.

Labor practices

Total Rewards for employees

As our industry becomes more competitive, it is vital that we continue to offer current and prospective employees an attractive package of pay, benefits and professional development.

Xcel Energy is committed to providing employees with market-competitive compensation and benefits. We use best practices and benchmarking to ensure the programs we offer are aligned with the market and attractive to our workforce, while also finding ways to manage costs to keep our compensation and benefits programs financially viable.

We have reviewed and made changes to our contracts with benefit providers to help manage costs at their source rather than change plan design or increase cost to our employees.

2018 Results

- Forbes recognized Xcel Energy as one of the World's Top Regarded Companies and World's Best Employers, as rated by employees.
- We developed a new parental leave policy that allows non-bargaining employees up to an additional four weeks paid time off to care for a new addition — whether it is through birth, adoption or foster care.
- Employees participated in 440,000 internal learning opportunities as recorded through our Learning Management System.
- Our tuition reimbursement program supported 256 employees with their continuing education, with annual reimbursements totaling $806,755.
- We identified 286 "ready now" successors to key positions around the company — potential successors that possess the necessary skills to make a seamless transition if needed into a role for which they have been identified.

Employee Total Rewards

Xcel Energy's Total Rewards package includes base and variable compensation, along with benefits like health and well-being, retirement and pension, paid time off, recognition and talent development. We have a pay-for-performance philosophy, recognizing and providing larger rewards to our best performers. Base pay is influenced by job descriptions and external market pay data, as well as the employee's skills, experience and job performance. Bargaining unit employees are paid in accordance with their collective bargaining agreements.

Our annual incentive plan includes three award opportunities:

- Annual Incentive Program (AIP) Year-end
- I Deliver
- Innovator awards

These awards are given to exempt, non-bargaining employees who went above and beyond and who achieved results that were aligned with Xcel Energy's corporate goals. Our non-exempt employees are eligible for Spot-On bonus awards in recognition of above-and-beyond results in their responsibilities. Employees and leaders can also recognize one another through an online system, and when appropriate, give points-based awards that can be redeemed for merchandise and gift cards.

We provide a Total Rewards Statement that shows our employees the full value of the pay and benefits they receive. It offers a personalized snapshot of pay and benefits information, as well as links to additional program and service information. Employees can access their individual statements online.

Benefits

A significant portion of our investment in employees is made through a benefits package that remains competitive in the marketplace. Offering a comprehensive approach to well-being, Xcel Energy provides programs that address the physical, emotional and financial welfare of employees.

We are committed to supporting the health of employees and offer a medical plan that provides comprehensive coverage, encouraging preventive care so health issues can be identified.

Our Employee Assistance Program connects employees with free, confidential support to resolve a variety of issues including mental health counseling, elder care, financial and legal advice.

Xcel Energy continues to offer defined benefit pension plan along with a 401(k) savings plan, which demonstrates our commitment to partnering with employees to meet their long-term financial goals. Unlike many employers who have frozen pension plans or reduced contributions to 401(k) accounts, we continue to contribute to these plans at market-appropriate levels to indicate our commitment to help employees save for the future.

Xcel Energy Benefits Package for Eligible Non-bargaining Unit Employees*

Health Benefit Plans

- High Deductible Healthcare Plan (HDHP)
  - Reasonable and affordable premiums
  - Includes a Health Savings Account (HSA) employees can contribute pre-tax dollars
  - In aggregate, Xcel Energy pays approximately 75% of medical costs
- Dental plan
  - Xcel Energy offers a basic and enhanced dental plan
- Vision plan
  - Xcel Energy offers access to a vision plan
- Wellness Program
  - Financial incentives to encourage healthy lifestyles
  - Wellness coaching including tobacco cessation, weight management, diabetes management, onsite yoga and flu shots
  - Fitness center reimbursements

Retirement Plans

- Pension plan
  - 5% cash balance plan for new employees and legacy formulas for other employees
  - 100% paid by Xcel Energy
- 401(k) savings plan
  - Savings Plan allows employees to save for their future through automatic payroll deductions (pre-tax, Roth 401(k) after-tax or a combination of both)
  - Variety of investment options (cash, bond and stock investments)
  - Company matching contributions

Income Protection

- Life Insurance
  - Xcel Energy covers the full cost of basic life insurance
  - Offers voluntary supplemental and dependent life insurance coverage
- Paid Time Off
  - Xcel Energy covers the full cost of short-term and long-term disability for eligible employees

Work/Life Balance Programs

- Employee Assistance Program (EAP)
- Paid Time Off
  - Vacation/PTO
  - Sick leave

- Transit pass subsidies
- Adoption assistance
- Parental leave allows employees up to an additional four weeks paid time off
- Flexible Spending Accounts
  - Dependent care
  - Medical
  - Transportation

Professional Development Programs

- Tuition reimbursement
- Variety of internal and external development opportunities

*Xcel Energy employees are eligible for benefits based on employee group and status (regular full-time and regular part-time non-bargaining). Bargaining unit benefits are based on the contract negotiated with the specific local union.

Professional Development

Total Rewards is more than pay and benefits. It also includes providing employees opportunities for professional development. Xcel Energy is committed to professional development and maintaining an environment where learning and growth can occur. Employees are ultimately responsible for owning and managing their own professional development. However, we expect managers to encourage development through feedback, coaching and support.

With this in mind, we offer employees resources and tools to support their personal and professional development, including a Learning Management System (LMS), which provides e-learning, virtual and traditional training options. We also provide employees with development planning tools, assessments and suggestions for practicing new skills and behaviors.

2018 Professional Development Opportunities

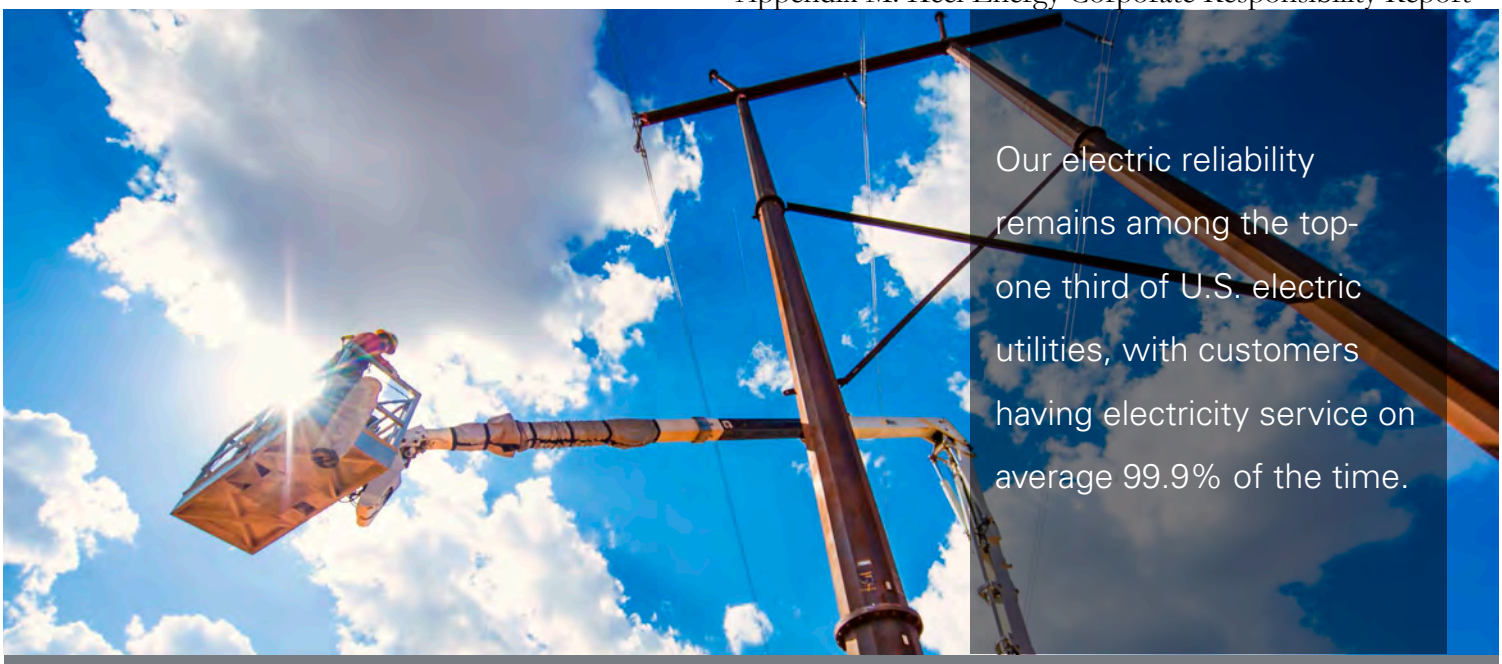
Learning Programs	Opportunities
Online Courses	We offer an extensive catalog of online courses for employees to complete, ranging from technical and computer application training to professional and management training to compliance-related education and more. Some of these training programs are mandatory.
Classroom Courses	Employees can choose to attend a number of different training programs that are taught in person, ranging from safety and compliance-related classes to professional development classes to technical trainings. Depending on job responsibilities, some of these courses are mandatory.
Career Development Assignment Program	The Career Development Assignment Program is an intentional effort to support the development of high-performing employees through cross-functional experience aligned to business needs. Employees may be pre-identified through succession planning or, in some cases, the opportunity may be posted.

2018 Leadership Development Opportunities

Programs	Opportunities
Succession Planning	Talent Review identifies individuals who might be successors for critical positions at Xcel Energy. Through this systematic process, executives and managers discuss assessments regarding the long-term performance, leadership potential and career aspirations of their employees. Working in teams, they determine the developmental readiness of each employee, create customized development plans and identify talent gaps. Potential "ready now" successors are identified for key positions around the company. This ensures there are successors that possess the necessary skills to make a seamless transition into the role for which they have been identified. In 2018, about 202 key positions were identified and nearly 2,300 leaders and individual contributors were assessed during Talent Review.
Coaching in the Moment	Coaching in the Moment is a course that teaches leaders how to coach employees by using insightful observations, shifting their worldviews and empowering them to take meaningful action. Offered both in a classroom and online setting, this training is transforming how our leaders interact with their team members by helping them learn to resolve their own dilemmas.
Leadership Essentials	Leadership Essentials is an online portal accessible to all employees that features over 25 learning topics, such as managing relationships, influencing and development planning. Each topic contains informational content, practice activities, and links to curated internal and external resources such as helpful articles and videos.
Leading the Call	Leading the Call is a small cohort-based executive development program for high potential, senior leaders. A cohort will meet regularly over several months to engage on topics such as culture, leading change, self-awareness, cross-functional and enterprise thinking, and to prepare for the highest levels of leadership. To put learning into action, they also divide into small groups to address real business challenges. In 2018, a cohort of 17 leaders went through the program.

Equal Employment Opportunity and Non-discrimination Policies

Our corporate Code of Conduct prohibits all forms of discrimination and promotes equal employment opportunities. We have Equal Employment Opportunity and Non-Discrimination policies in place that apply to all Xcel Energy operating companies and subsidiary companies. Xcel Energy provides equal opportunity in hiring, training, compensation, promotion, termination, transfer and all other terms and conditions of employment, without regard to race, color, religion, creed, national origin, gender, age, disability, veteran status, sexual orientation or any other protected class status in accordance with applicable federal, state and local laws.



Energy reliability, fuel diversity, nuclear generation, security, emergency preparedness and advanced grid

Reliable and secure energy

We provide 24/7 convenience for millions of customers who depend on us for the fundamentals — reliable, affordable and safe energy from an increasingly cleaner mix of resources.

Above all else, our fundamental purpose is to provide customers with safe, clean, reliable and affordable energy. We continually invest to strengthen and upgrade our infrastructure — the generating plants, power lines, pipelines and other systems that serve customers. This includes diversifying our energy supply to provide energy from a reliable mix of resources while managing cost, environmental impact and making sure we don't depend too heavily on any one energy source. As we decide where to invest, we naturally consider projects that address all these considerations while providing the best overall value for all stakeholders — addressing the interests of regulators, policy makers, communities, customers and investors.

To run and maintain our system, we must also invest in our people to cultivate a culture of continuous improvement where we strive to work better and smarter for our customers. Among our operations employees, we have a mantra of getting better every day.

2018 Results

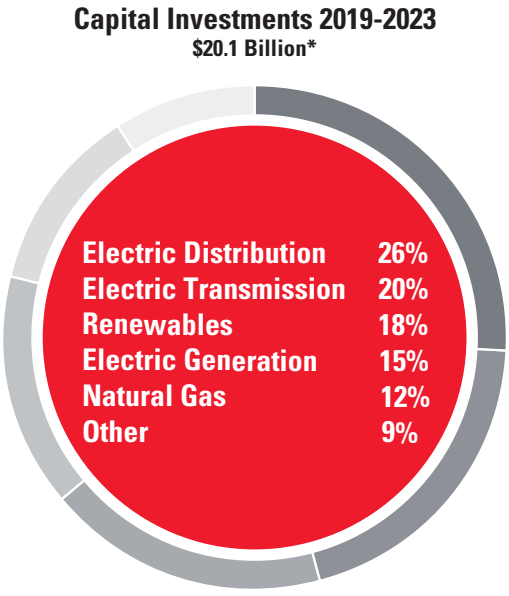
- Regulators approved our Colorado Energy Plan that is supported by a diverse coalition of stakeholders, including environmental groups, consumer advocates, municipalities and customers. Under the plan, we will retire 660 megawatts of coal-fueled generation and add 1,100 megawatts of wind, 700 megawatts of solar, 275 megawatts of battery storage and 380 megawatts of existing natural gas resources. We will own 500 megawatts of the new wind and all of the natural gas resources.

- We reached a $650 million agreement to purchase the Mankato Energy Center, a 760-megawatt natural gas power plant. The plant currently provides power to our customers under a purchased power agreement with Southern Power, a subsidiary of Atlanta-based Southern Company. Purchasing the plant is a great value for customers because of the cost savings and operating flexibility it can provide as we transition to clean energy and reduce reliance on coal.
- We delivered the Rush Creek wind project on time and within budget. The 600-megawatt project is our largest constructed to date. We also made progress advancing eight other wind projects across seven states to different stages of development. Xcel Energy is building and will own the projects, totaling 2,550 megawatts of capacity. In addition, we expect to own an additional 470 megawatts of wind capacity from four projects that others are building or repowering.
- Under our Advanced Grid Intelligence and Security initiative, we deployed 100 network and more than 200 advanced distribution devices, and implemented a secure, two-way private network that will function as the foundation for advanced technology in Colorado and Minnesota. This work is just the beginning of the initiative that will upgrade the power grid to better serve customers and enhance our ability to efficiently restore power and improve reliability. The initiative will create a platform that provides enhanced visibility and control of the energy grid through the integration of modern information system technology and traditional distribution systems.
- Xcel Energy was one of several companies recognized with a special 2018 Emergency Assistance Award by the Edison Electric Institute. Approximately 200 of our line workers and support personnel traveled to Puerto Rico to help restore power following the devastation of Hurricane Maria.

Investing for the Future

Over the next five years, we plan to invest $20.1 billion in projects that, in addition to ongoing maintenance and repair, will improve energy production, strengthen the energy grid, ensure security and offer customers more options.

We are investing in projects that offer the most value for customers.



*Includes the purchase of the Mankato Energy Center and the Jeffers and Community Wind North repowering projects, which are awaiting regulatory approval in 2019.

System Resource Planning

We are required by some state regulatory commissions to regularly conduct a system resource planning process. The process varies by state, but generally begins with Xcel Energy filing a proposed long-term resource plan with the public utilities commission, which is then evaluated by regulators, as well as customer, environmental and community stakeholders. The plans assess the overall resources we need to serve the energy needs of our customers. The plans also discuss many other factors associated with our generation portfolio including transmission needs and our total load obligations, which are influenced by items like energy efficiency program goals.

Once the plan is approved, it may result in the need to add resources to serve our customers. We then typically release one or more requests for proposals, which may be general or targeted toward specific resources, such as natural gas or renewable energy. As the regulatory commissions decide on the resources to be acquired, our stakeholders have the opportunity to provide input.

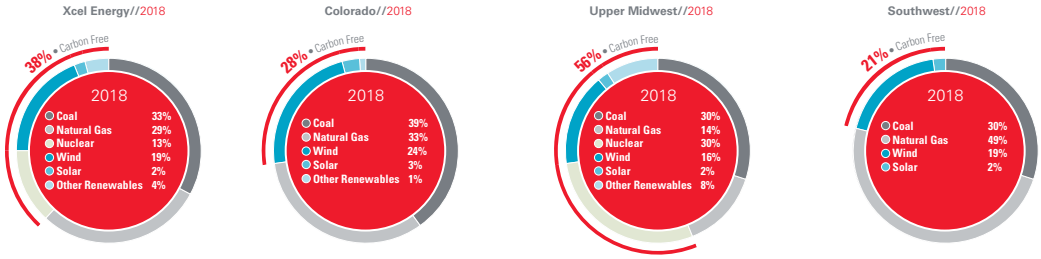
In Colorado, regulators approved the Colorado Energy Plan in August 2018, which completed phase two of our 2016 resource plan. We are now acquiring the new renewable, battery and natural gas resources that are part of the plan.

In the Upper Midwest, we are preparing to file a new resource plan in July 2019. We have announced our 2030 goal to reduce carbon emissions from the electricity that serves our customers 80% while maintaining reliability and keeping customer bills affordable. We are currently working with stakeholders on the upcoming proposal to achieve this goal.

In our southwestern states, we are only required to file a resource plan in New Mexico. In early 2018, regulators in New Mexico and Texas approved our plans to add 1,230 megawatts of new wind generation for the region in 2020. We are now implementing the wind projects, which are expected to meet customer energy needs while saving money long term through lower fuel and other costs. We anticipate filing updated resource plans in New Mexico as our system load requirements and generation portfolio continues to evolve.

Our Energy Supply

Xcel Energy provides electricity from a diverse mix of energy sources, including coal, natural gas, nuclear and renewables. We delivered more than 102 million megawatt hours of electricity to customers in 2018 produced at Xcel Energy generating plants and purchased from third-party suppliers.



Utility Operations

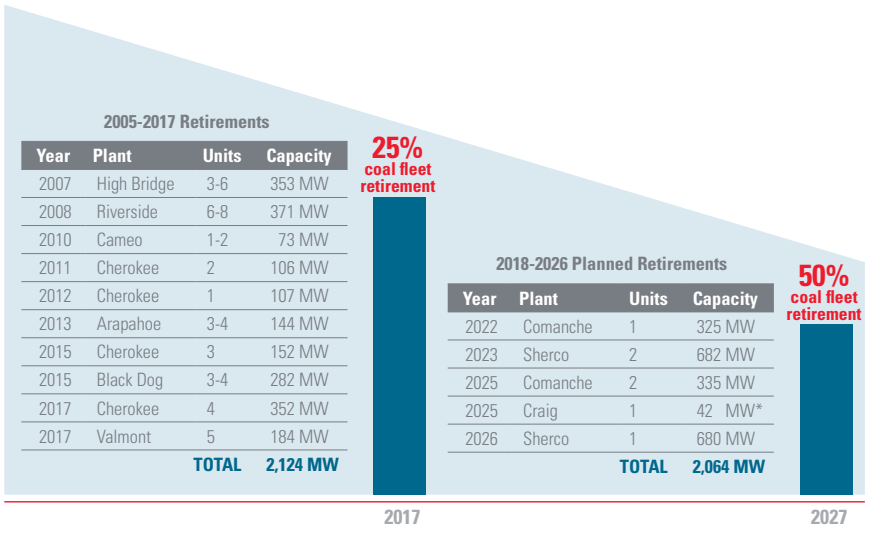
Generating Electricity

We currently own 79 generating plants that operate across our eight-state service territory with more than 18,000 megawatts of capacity. Traditionally, our generation portfolio has depended on coal, but we are transitioning our energy supply away from coal to rely more on renewable energy and energy sources that enable renewable integration, such as flexible natural gas generation. We need technologies that can be dispatched to balance the peaks when customer use exceeds renewable generation and valleys when renewable generation exceeds customer use.

By 2026, we will retire 23 coal units under approved plans, representing approximately 50% of the coal-fueled capacity we own. When we file our proposed Upper Midwest Energy Plan in July 2019 for consideration with the Minnesota Public Utilities Commission, it will include additional coal retirements. We will propose closing the Allen S. King Generating Plant in 2028 and Sherco Unit 3 in 2030 — our last remaining coal plants in the region.

As we retire resources and replace them with new ones, we are making the transition responsibly and thoughtfully for the communities and employees who are impacted. To date, we have managed plant closures through attrition and employee transfers to different company work locations. For our communities, we continue to partner on economic development opportunities, and we expect the transition will also create new jobs and economic development opportunities throughout our service area.

Xcel Energy's declining reliance on coal enables significant reductions in carbon and other emissions.



*Based on Xcel Energy's 10% ownership interest in Craig Unit 1.

We continue to invest in wind energy under our Steel for Fuel strategy, capitalizing on historic-low wind prices and available tax credits to install new wind farms — where the cost to build the projects is offset by future fuel savings. Xcel Energy is recognized as a national leader in wind energy. Currently, most of the wind power on our systems is contracted under long-term agreements with third parties, but that is changing under our Steel for Fuel strategy.

Our two nuclear generating plants in Minnesota play an essential role in our energy future, providing 1,657 megawatts of reliable, carbon-free capacity, enough to power 2.3 million homes. The plants delivered exceptional performance in 2018, generating more than 14.6 million megawatt hours of energy. It is a record for the plants, which produced power 96% of the time while reducing operating and maintenance costs by nearly 3%. Both plants also received the top rating under the Nuclear Regulatory Commission's Reactor Oversight Process that classifies the nation's nuclear reactors into categories based on safety. Our Monticello Nuclear Generating Plant was honored with the Institute of Nuclear Power Operations' Excellence Award for achieving an excellent rating on the plant's annual evaluation.

Delivering Power

Xcel Energy operates nearly 21,000 miles of power lines and more than 1,200 substations and other equipment to safely and reliably deliver electricity to customers.

Transmission lines are a vital link to bring electricity over long distances from power sources to substations closer to homes and businesses. Xcel Energy is one of the fastest growing, investor-owned transmission systems in the country.

The following are notable projects in 2018:

- As part of the Power for the Plains initiative in New Mexico and Texas, we completed nearly 250 miles of new transmission. The largest effort was the new 90-mile 345-kV Hobbs-China Draw project in New Mexico that provides a new source of bulk power to meet growing electricity demand in Eddy and Lea Counties.
- We completed the 83-mile, 345-kV transmission line between Missile Site Substation and the new Pronghorn and Rush Creek II Substations. The new line carries power from the Rush Creek wind project to Colorado business and residential customers.
- In Minot, North Dakota the 20-mile Magic City-McHenry 230-kV transmission line and new substation went into service, providing another source of electricity and improving reliability for the area. Xcel Energy crews partnered with the U.S. Fish and Wildlife Partners for Wildlife program to plant 40 acres of pollinator habitat around the new substation.
- The La Crosse-Madison Transmission Line Project, also known as the Badger Coulee Project, was completed and energized in December 2018. The approximately 180-mile, 345-kV line provides electric system reliability to benefit western Wisconsin communities, the state of Wisconsin and the entire Upper Midwest region and provides access to lower-cost power and renewable energy.

In addition to these projects, we successfully started a critical rebuild project near Boulder in difficult terrain. In three days, we hauled and set 19 steel transmission structures by helicopter to rebuild a 110-year-old 115-kV line that runs between the El Dorado Substation and the NCAR Substation in Colorado. The line is located in Boulder Open Space in an area largely inaccessible to vehicles.

Fueling Homes and Businesses

Xcel Energy is the tenth largest provider of natural gas service in the country, based on number of customers. We fuel the homes and businesses of approximately 2 million customers in Colorado, Michigan, Minnesota, North Dakota and Wisconsin, and also operate some gas transmission in South Dakota and Texas. Natural gas is an extremely safe and efficient way to heat homes, from both a cost and environmental perspective, especially in our cold weather service areas. With more than 2,200 miles of transmission and 35,000 miles of distribution pipelines already in service, we plan to add approximately 750 miles of new pipeline over the next five years.

To maintain safe and reliable gas service for everyone, we continue to upgrade and renew our natural gas pipelines and other equipment. We finished replacing all cast-iron pipes on our system in 2014. Low natural gas prices have made it possible to invest in our system and accelerate upgrades with minimal impact to customer bills.

Xcel Energy purchases natural gas from third-party producers to generate electricity and distribute to customers for use in their homes and businesses. Natural gas production is governed by federal, state and local regulations, with additional regulations under consideration. We expect all our suppliers to conduct their operations responsibly and in compliance with all regulatory requirements.

We can play an important role in ensuring natural gas is produced responsibly and as sustainably as possible. To help promote sustainable production upstream of our operations, we joined the Natural Gas Supply Collaborative — a group of the nation's large natural gas purchasers. Collaborative members have called for and are encouraging enhanced transparency from natural gas producers across 14 social and environmental metrics.

Vegetation Management

Xcel Energy's Vegetation Management department manages millions of trees across more than 47,000 miles of distribution right-of-way and nearly 21,000 miles of transmission right-of-way throughout our service territory. For 24 years, the Arbor Day Foundation has recognized our company as a Tree Line USA utility for our commitment to proper tree pruning, planting and care.

We use industry best practices such as Integrated Vegetation Management, which encompasses a progressive system of information gathering and helps us develop compliant solutions for controlling vegetation near electric and natural gas facilities. The practice helps us achieve our vegetation management goals in an environmentally sensitive, socially responsible and cost-effective manner.

In addition, pruning methods comply with standards set by the American National Standards Institute and the Tree Care Industry Association, which are endorsed by the International Society of Arboriculture.

For our distribution and transmission lines, work is generally performed on a four- to five-year cycle. In Colorado, we have established a Mountain Hazard Tree Program that helps us stay ahead of the tree mortality caused by the Mountain Pine Beetle. Our practices seek to balance our customers' need for reliable energy while respecting the natural environment that surrounds our facilities. For example, we work with landowners to determine if trees and other vegetation can be deemed compatible with safe operation of our electric lines.

In our efforts to comply with governmental regulation and to better ensure electric system reliability, our transmission line vegetation management program emphasizes the removal of incompatible vegetation to promote long-term vegetation control. In many cases, this means removing trees in areas where trees had been pruned in the past.

We employ manual and mechanized clearing techniques, as well as responsible herbicide applications. All herbicides used are products registered by the EPA and the appropriate state regulatory agency. The herbicides are applied by licensed applicators.

Safety: Grid Resilience and Security

As the use of technology and interconnected systems expands, the grid is increasingly subject to attack by those who might choose to do us harm, whether for criminal purposes or as part of an effort to undercut our national security. Ensuring our energy grid is secure from cyber and physical threats is an ever-evolving responsibility that demands our constant vigilance and is a top priority for Xcel Energy.

We continue to implement an array of efforts to increase preparedness and decrease vulnerability. Our Enterprise Security Services organization oversees coordination of all security efforts, including employee training and awareness, compliance with federal regulations and corporate security governance.

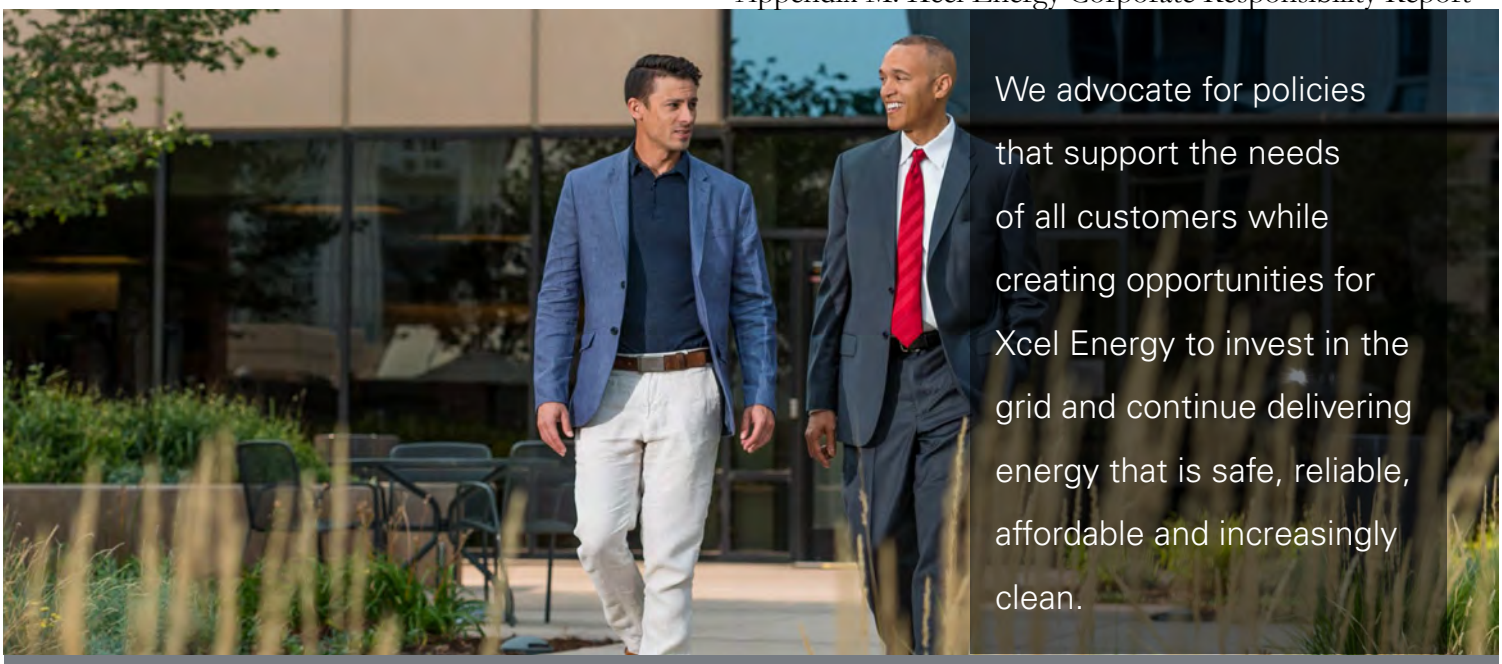
Through our state-of-the-art Cyber Defense Center, we monitor and protect our networks 24 hours a day, seven days a week. Our cyber security program is risk-based and uses known standards and best practices which encompass security controls that provide adherence to government and regulatory requirements. It includes "Defense-in-Depth" methodology that provides multi-layered safeguards to reduce or eliminate single points of failure and weakness.

While it is impossible to protect our systems and grid against every malicious attack, we are taking reasonable and prudent steps to prevent, detect and mitigate the impacts of an intrusion. We are hardening systems to limit opportunities for attack and deploying enhanced monitoring and detection systems to help us promptly identify any successful intrusion.

In 2018, we introduced the Enterprise Command Center, which provides constant monitoring for natural and man-made events that could be disruptive to Xcel Energy's ability to serve our customers, protect our assets and keep our employees safe.

We engage with other members of our industry, other segments of the economy and the government to engage in threat information sharing and test our combined capabilities to respond to an attack. Individually and in collaboration with other energy providers, we are working to prepare our employees and systems for responding to a successful attack by developing inventories of spare equipment and processes for preserving reliability in the unlikely event our key operational systems were to be compromised.

As part of our commitment to security, Ben Fowke, Xcel Energy chairman, president and CEO, is a member of the National Infrastructure Advisory Council, which advises the President on ways the nation can protect its critical infrastructure. He also participates in the Electric Sector Coordinating Council, which serves as the principle liaison between the federal government and the electric power sector on these issues.



Public policy engagement

Public policy

Xcel Energy engages in policy and regulatory issues important to ensuring our ability to provide all customers with the energy service and products they want and value.

As the energy industry continues to undergo a significant transformation, it is essential that we participate in the policy developments that will determine our future, representing the interests of our company and its many diverse stakeholders. With more than a century of experience in meeting the energy and financial needs of customers, communities and investors, we aim to share our expertise with policy makers and elected officials to better inform and guide decisions that impact the service we provide.

While we may not always share the same positions, we participate in industry, trade, business and other associations to provide our perspectives and to learn from the perspectives and experiences of others. We discuss issues and solutions with policy makers on all levels — local, state and federal. We also provide informal input and formal testimony and comments on proposed legislation and regulation.

Our policy priorities focus on advancing research of new clean energy technologies and developing the right conditions that allow technologies to be seamlessly adopted by our existing system, once they are ready. To help facilitate or accelerate our industry transformation, we are exploring targeted incentives and the right mandates that will not increase customer costs.

2018 Results

- When we announced the company's industry-leading carbon vision in late 2018, policy makers, community leaders and environmental advocates from around the country expressed their support for our new goals. We worked extensively with stakeholders on this commitment to help confirm our goals and advocate for the policy objectives for achieving them.

- We worked with public utilities commissions in all of our states to determine how cost savings associated with major tax reforms passed by the U.S. Congress in late 2017 will be shared with our customers. Overall, our average electricity rates were 0.2% lower in 2018 due to customer refunds associated with the Tax Cuts and Jobs Act.
- The President's National Infrastructure Advisory Council released its report on how the nation can best prepare for and recover from a catastrophic power outage. Xcel Energy's chairman, president and CEO Ben Fowke participates on the council, and we were significant contributors to the report, which examines how our nation can strengthen its long-term power outage prevention and recovery capabilities.
- The 2018 Farm Bill signed into law at the end of the year includes a provision that we supported to authorize the U.S. Forest Service to work with utilities to manage vegetation adjacent to transmission rights-of-way on federal lands. The program supports overall forest health and can help protect utility infrastructure from wildfires.
- The U.S. House of Representatives passed a bill in spring 2018 that allows for consolidated interim storage facilities and encourages the finalization of a permanent repository for radioactive waste from the nation's nuclear generating plants. We supported the bill and continue to work on a solution to this long-standing issue. In May 2019, our Chief Nuclear Officer testified in support of similar legislative proposals in the U.S. Senate.

Public Policy Principles

Our energy landscape is evolving, driven by new technologies and customers demanding new energy options and a reduced carbon footprint. In this new landscape, we are striving to meet the interests of individual customers while continuing to deliver safe, clean, reliable energy at an affordable cost and creating opportunities for our company to invest in the grid. To meet the challenges ahead, we follow these four core principles as we support the transformation of our energy landscape.

- **Utilities are engines for innovation and deployment at scale.** The vertically integrated utility model with regulatory oversight is well-positioned to adapt to changing energy markets, new technologies, new customer preferences and community goals. This model provides inherent system value through efficiency, optimization and economies of scale that benefit all customers and balances the allocation of risks and benefits between the utility and its customers. As such, we are well-positioned to grow the market for value-added services — such as energy storage, microgrids, electric vehicles, and solar power — and to do so at scale and in a manner that benefits all customers.
- **We can enable greater customer choice without eroding fundamental rate design principles.** Ideally, rates should reflect the cost of service provided to a customer and continue to prioritize affordability because reliable, affordable energy is essential to a strong economy and protecting low-income customers. Matching rates to price signals moves the system to a more efficient state of operation and options like time-of-use pricing can incentivize customers to shift energy use to more desirable times.
- **The grid is our economy's greatest physical asset and utilities are its stewards.** More than a collection of wires, the grid is an integrated system of plants, wires, transformers, substations, control systems, and other equipment that is foundational to our economy. In our jurisdictions, the vertically integrated utility model — from supply to delivery — is the most effective way to economically maintain a reliable and secure grid and make the investments necessary to meet customer needs and achieve environmental goals.
- **Our economy will continue to electrify and utilities should be the architects of that transition.** There are clear signs that our economy is undergoing a transformation to greater and cleaner electricity usage, and through lower-carbon electricity and electrification, we can further reduce greenhouse gas emissions. The transition must be done as part of a thoughtful, deliberate, policy process — one that builds upon past utility successes and engages customers and communities who wish to actively participate.

Our society does not need a new business model for utilities in order to meet modern day challenges. We need a modernized version of the model that has been delivering for decades. The utility industry, and Xcel Energy as a leader in the industry, is well poised to meet these challenges in direct partnership with our regulators and our customers.

Advocacy for Innovation and Developing Advanced Energy Technologies

We continue to engage in and work to address policy issues at all levels of government. One of those issues, and a significant objective for us going forward, is establishing a path for the development of advanced, carbon-free 24/7 technologies that we will need to fulfill our aspiration to serve customers with 100% carbon-free electricity by 2050.

Federal and state policies must support the development of new, carbon-free, 24/7 resources to complement our existing and growing portfolio of renewable energy, energy efficiency and demand response resources. We can also send clear signals to the market around price, capabilities and timing for when these technologies will be needed. In this way, utility resource plans provide the market signal — the state-level "technology pull" — from which the private sector and national laboratories and federal agencies can align their investments. This investment in further research and demonstration will help develop the carbon-free solutions we need at the cost and scale at which our sector will need them.

We are advocating for policies that help take advanced clean energy technologies from demonstration stage to commercialization by creating programs to manage cost and spread risk. In order for this to happen most effectively, it is important that developers leverage existing infrastructure and current market conditions. There is also opportunity to provide incentives for clean energy innovation and reducing barriers to new development. These incentives can be powerful mechanisms for deploying these technologies in the marketplace, but they require careful design. For that reason, we are working on policies that allow the efficient use of existing and new tax incentives.

Political Contributions and Lobbying

Xcel Energy has a corporate policy that sets guidelines and rules for political contributions and to ensure all contacts with government officials meet legal and ethical standards.

Our board of directors, leadership and employees must comply with all federal laws restricting the making of political contributions or expenditure using corporate funds in connection with elections for federal offices. When communicating about matters involving Xcel Energy, the board of directors, leadership and employees must accurately convey corporate messages and support the Xcel Energy brand. Xcel Energy's Political Contributions Report provides corporate contributions and dues paid to trade associations.

Employee Policy Engagement

Grassroots advocacy is important to Xcel Energy because our industry is so complex. Xcel Energy employees can help educate their friends, neighbors and community leaders by participating in:

- **Legislative Days:** We offer a special day at the capitol in each of our jurisdictions for employees to meet their elected officials and learn more about the legislative process.
- **Local events and meetings:** Employees can represent the company at community meetings and special events.
- **Political Action Committees:** Employees can voluntarily participate in seven different groups that are organized and run by employees.

Political Action Committees

Xcel Energy sponsors seven Political Action Committees or PACs organized and run by employees, six at the state level and one at the federal level. Participation in the company's PACs is completely voluntary and is part of the engagement opportunities that we offer employees.

Each of the company-sponsored PACs has its own board of directors elected by its members that make contribution decisions. All of our PACs are strictly voluntary, and there are no employment benefits based upon participation. Each complies with all applicable local, state and federal laws.

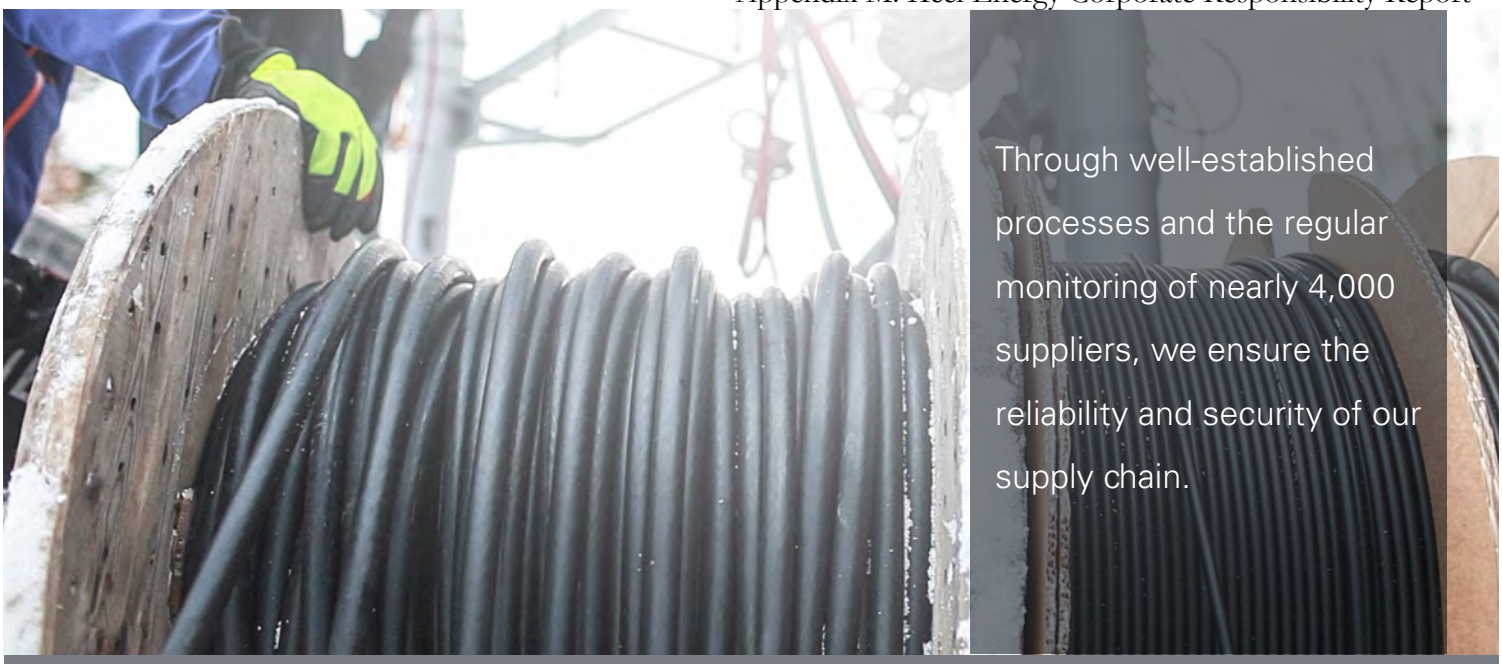
2018 Xcel Energy Political Action Committee Activity

PAC	Employees Participating	Total Employee Contributions to PAC	Total Contributions Made to Candidates*
Colorado (Western PAC)	327	$28,927	$38,375
Minnesota**	329	$48,705	$44,700
North Dakota	24	$1,945	***$6,200
South Dakota	0	$0	***$3,900
Texas/New Mexico (SCOPE)	368	$35,787	$59,050
Wisconsin	342	$36,614	$27,488
XPAC (federal PAC)	389	$246,220	$253,000

*Funds contributed by employees can accrue over multiple years and are not necessarily distributed in the same year they were contributed. Contributions vary by year and are typically lower in nonelection years or years when state legislatures are in session.

**The state PAC in Minnesota is operated outside of Xcel Energy in accordance with state law that prohibits the use of corporate resources to support the PAC; although, payroll deduction is specifically permitted in Minnesota. Activity for the Minnesota PAC is only included in this report for transparency and informational purposes.

***With the exception of 24 North Dakota state PAC-only contributors, all contributions made to both the North Dakota and South Dakota state PACs were made via funds transferred from the Minnesota state PAC in compliance with all federal, state and local campaign finance laws.



Procurement practices

Supply chain management

Suppliers play a vital role in our company's ability to manage costs, operate efficiently and provide the ongoing service that our customers value.

We continuously look for ways to improve efficiency and reduce the cost of doing business through our supply chain processes. As we negotiate favorable prices or find ways to reduce waste, we pass the savings on to customers, helping to manage their energy costs.

Much of our spending on materials and services is with local businesses, which supports economic prosperity in the communities we serve. We also look for business partners that share our priorities around safety, diversity and environmental protection and that will adhere to our Code of Conduct.

2018 Results

- We spent $533 million, directly and indirectly, with businesses owned by women, minorities or veterans, achieving our goal to spend 12.4% of total annual spending with diverse suppliers.
- Nearly 70% of our supply chain spending was with local businesses, totaling more than $2.9 billion. While not all materials and services can be sourced locally, we build relationships and set targets to support our area economies.
- Through our supply chain, we saved approximately $307 million, which was first-quartile performance in a benchmarking of peer utilities.
- The Hispanic Chamber of Commerce of Metro Denver named Xcel Energy its Corporate Advocate of the Year in early 2019 for the company's ongoing support and work with member companies. Three of our largest contractors in Colorado are chamber members, including Alvarado Construction, Campos EPC and Redeker Excavating.

Supply Chain Process

Our central Supply Chain organization is responsible for the sourcing and procurement of goods and services, materials management, fleet management and accounts payable for all of Xcel Energy's operations. The group negotiates contracts for everything from day-to-day business necessities, such as office supplies and furniture, to capital items used to construct, operate and maintain our generation and transmission assets, including transmission poles and transformers. They develop supplier and contractor management strategies and policies, handle accounts payable and execute company-wide sourcing and procurement strategies.

We employ a systematic sourcing method to deliver needed materials and services to the right place at the right time for the right price. To select suppliers, we use a five-step sourcing process that includes: preparation, request for information, request for proposal, contract evaluation and negotiation, and implementation.

Four key business objectives — each associated with specific initiatives — drive our supply chain strategy. These include:

- Maximizing investment yield
- Achieving operational excellence
- Managing risks and opportunities
- Supporting community and environmental leadership

In 2019, we expect to spend approximately $4.58 billion on materials and services that fall into 35 categories with more than 800 subcategories. These categories are used to determine risk, opportunity and negotiation leverage with suppliers. We have developed guidelines for bid analysis for all categories. Within these guidelines, up to 20% of the bid analysis weight can be allocated to social and environmental factors such as diversity, safety and environmental performance.

2018 Supply Chain Spending Categories

Battery	Engineering Services	Meters	Steel Structures
Boiler Systems	Environmental	MRO Materials	Transformers
Cable and Wire	Fleet	Other Plant Systems	Transportation Services
Chemicals Gases and Lubes	Gas Materials	Property Services	Travel Services
Circuit Breakers	HR and Benefits	Radiation Protection	Turbine and Generator Systems
Construction	IT and Telecom	Revenue Cycle	Vegetation Management
Consulting Services	Logistics Integrator	Safety	Wind
Dry Fuel Storage	Maintenance Services	Solar	Wood Poles
Electrical Materials and Equipment	Marketing and DSM	Staff Augmentation	

Risk Management

Through our Supplier Qualification program, we use services such as Dunn & Bradstreet to regularly monitor all active suppliers for Office of Foreign Assets Control, Excluded Parties List System, OSHA and EPA violations, as well as criminal proceedings and disaster events. We assess suppliers' financial health, safety and use of diverse subcontractors before contracting with them, and suppliers who will have access to our confidential data must undergo a data security review.

Periodically, we conduct key risk assessments, looking at categories such as commodity price risk, supply continuity, quality and governance processes. We also design sourcing strategies that take into account multiple fulfillment locations and supply channels that can minimize potential supply disruptions in case of extreme weather or disaster-related events.

Our company works with a broad range of suppliers. The majority of our spending is with American suppliers, but we also do significant work with American-based affiliates of foreign suppliers and a small amount of work with foreign suppliers.

We have recently implemented a program for Security Vendor Risk Assessment that focuses on exposure to cyber, information and other security risks to Xcel Energy that could result from suppliers' access to our systems, confidential information and critical infrastructure. The requirement for this additional level of scrutiny is established in sourcing and contracting processes and involves a comprehensive testing of the supplier's security environment by our Enterprise Security Services team.

All contractors that provide services or materials at our sites are required to complete a contractor health and safety questionnaire and submit five years of safety-related performance data. Our contractor safety department reviews this data and may reject a contractor or require a safety improvement plan. We continue to monitor safety performance once a contract is implemented.

Tier	Annual Spending	No. of Suppliers	% of Annual Spend
Tier 1	More than $10 million	77	73%
Tier 2	Between $4-10 million	59	8%
Tier 3	Between $1-4 million	211	10%
Tier 4	Less than $1 million	3,382	8%

In addition, all contracts include a clause requiring suppliers to abide by equal employment opportunity and affirmative action mandates prohibiting discrimination on the basis of race, color, religion, sex, national origin, actual or perceived sexual orientation or gender identity of an individual, or physical or mental disability. All suppliers are expected to comply with our Code of Conduct, which is referenced in our standard agreement language and is made available to them upon request.

Supplier Classifications

We classify our suppliers in four tiers based on a combination of overall supplier spend and their importance or risk to our operations. Critical suppliers provide essential materials and services required to support daily operations. Tier one suppliers, including those who are critical to our operations, are part of our Supplier Relationship Management program. The program enables us to build longer-term contracts with these strategic suppliers and implement continuous improvement initiatives to benefit both the supplier and Xcel Energy in terms of costs and operations. Suppliers are also tiered, based on their total spend.

We support suppliers in non-tier one spend classifications through collaborative initiatives and programs. For example, we are a founding member of the ITASCA-Project in the Twin Cities, which is dedicated to helping smaller local suppliers grow through procurement opportunities. The ITASCA-Project group is made up of chief supply chain personnel from large corporations, such as Xcel Energy, U.S. Bank, Target, United Health and General Mills, who meet monthly to discuss ideas for supporting the local economy by growing the capacity of small- and medium-sized businesses.

Supplier Diversity Program

Our corporate policies underscore our commitment to supplier diversity by recognizing that it is in our best interest to encourage a broad base of supplier relationships. Using diverse suppliers contributes to the economic growth and expansion of the communities we serve. Our policy is to offer these businesses the opportunity to compete in our procurement for products and services. We develop and strengthen business relationships with diverse suppliers by:

- Conducting outreach efforts to seek, identify and encourage supplier diversity in our procurement processes
- Facilitating alliances and partnerships
- Educating businesses about our procurement and business processes
- Identifying and encouraging subcontracting (tier two) opportunities with major suppliers when direct participation is not possible

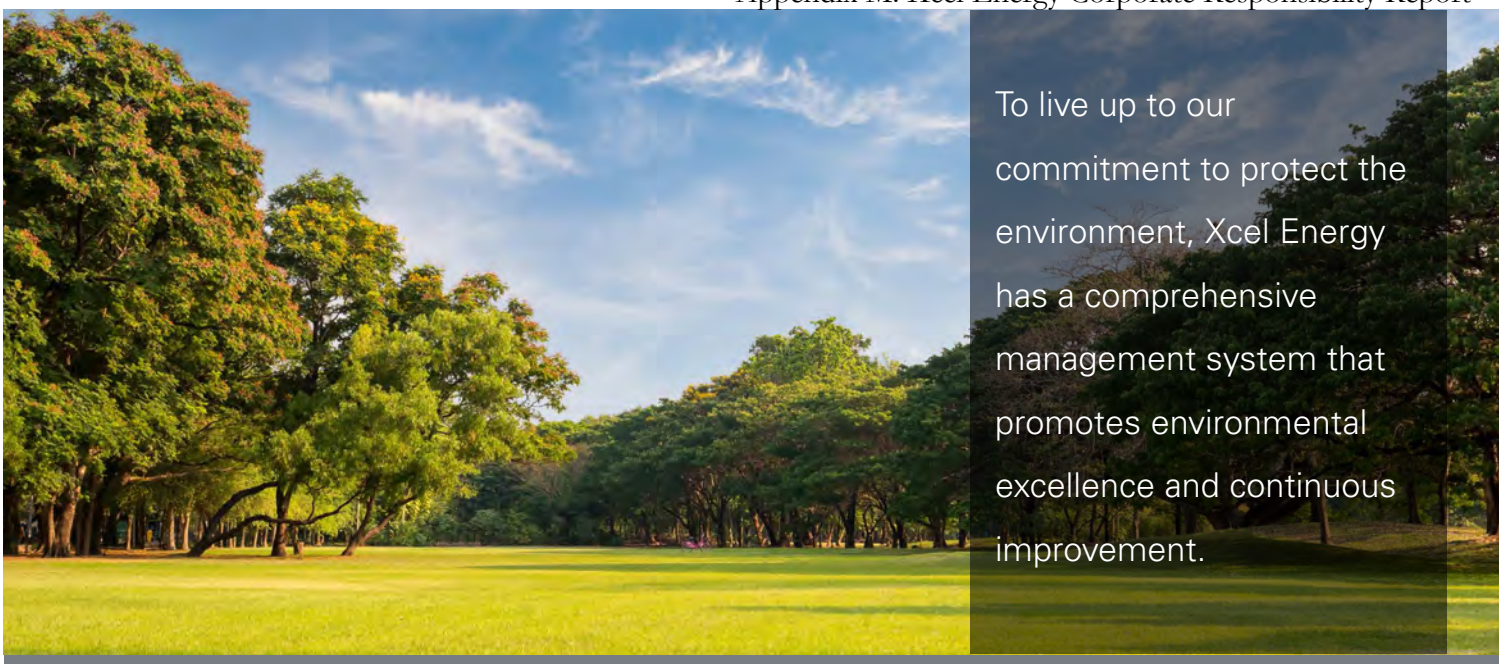
For 2019, we have set a goal of approximately $575 million, or roughly 12.5% of total spending, to spend with diverse suppliers. Most of the recent increases in our goal have been associated with Xcel Energy's continued investment in renewable energy, especially in constructing new wind farms. Wanzek, one of our diverse suppliers, is constructing multiple new wind projects on our system.

We are an active member of the Edison Electric Institute's Supplier Diversity Best Practices Group, as well as the Mountain Plains and North Central Minority Supplier Development Councils, the Women's Business Enterprise National Council, the National Association of Women Business Owners, the National Veteran Business Development Council, National Gay and Lesbian Chamber of Commerce and most local chambers of commerce in our service territory.

Annual Spending with Diverse Supplier

	2016	2017	2018
Dollars Spent	$401 million	$378 million	$533 million
% of Total Purchases	11.2%	10.5%	12.4%

Environment



Our policy and management approach

Environmental management

At Xcel Energy, protecting the environment is a priority and expectation for all employees and contractors as part of their jobs.

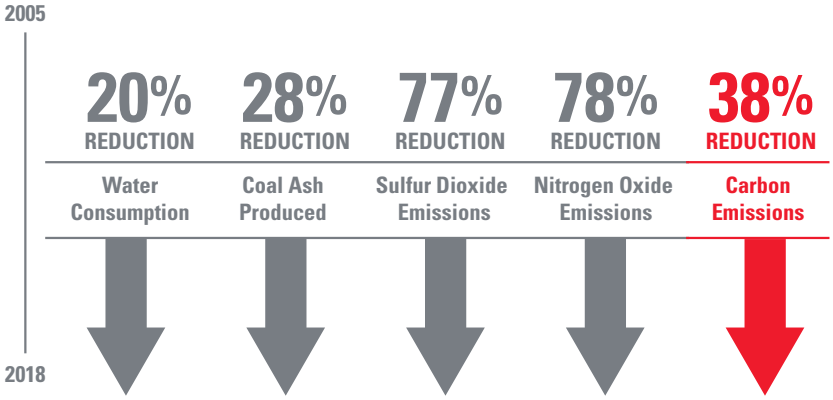
Every year we produce millions of megawatt hours of electricity and deliver millions of cubic feet of natural gas to serve our customers, fueling their homes and businesses. Our operations depend on natural resources — from fossil fuels to water and wind and solar — and they have an impact on the environment. It is an important relationship, and one that we are committed to managing carefully.

The customers and communities we serve depend on us and expect that through our daily operations we will protect our air and water, reduce waste and conserve natural resources.

2018 Results

- The Colorado Department of Public Health and Environment through its Environmental Leadership Program recognized Xcel Energy as a Gold Leader for the company's comprehensive Environmental Management System as well as its clean energy leadership and environmental stewardship.

We have significantly reduced our environmental impact since 2005.



Environmental Policy

Xcel Energy's environmental policy lays the foundation for the company's commitment and approach to protecting the environment and sets expectations for aligning our business practices with this commitment.

Our policy is to pursue environmental excellence through our corporate strategy and daily operations, striving to demonstrate leadership by doing what is right and advancing initiatives that will benefit the environment. At the same time, it is important that we balance our environmental commitment with the ability to provide customers with reliable and affordable energy.

Examples of our environmental leadership include:

- Significantly reducing carbon emissions through our proactive clean energy strategy
- Reducing other air emissions beyond what is required by regulations
- Surpassing state-level renewable standards by adding more cost-effective wind and solar
- Offering customers a robust portfolio of energy efficiency and renewable choice programs to meet unique needs and interests
- Conserving and reducing water consumption through electric generation
- Establishing more than 2,000 acres of pollinator habitat on the land we manage

As part of our decision making, we consider opportunities to reduce emissions, eliminate waste and conserve resources, including taking additional steps to protect wildlife. We also regularly monitor our operations to ensure we are acting in an environmentally responsible manner, and if appropriate, take steps to improve our efforts. We support environmental research and development, as well as environmental projects and partnerships in our communities.

To fulfill the responsibilities of our corporate environmental policy, we have more than 40 policies and procedures that ensure our ongoing environmental performance and that help to foster our commitment to environmental excellence.

All Xcel Energy employees, as well as contractors and vendors, are expected to follow these policies, and our employees are trained and empowered to take responsibility for protecting the environment through their jobs.

Environmental Principles

Engaging with stakeholders is essential to our work in addressing policy issues involving energy and the environment. As we engage on these matters with our regulators, elected officials, community leaders and others, we keep the following principles in mind:

- **Proactive solutions.** On behalf of customers, we have invested substantially in clean energy and environmental improvements. We continue to look for ways to proactively address environmental issues, especially when we can improve efficiency and reduce costs.
- **Rewarding leadership.** We believe that environmental and clean energy policy should appropriately recognize the environmental benefits of our proactive efforts made on behalf of our customers and communities.
- **Supporting technology.** Environmental and clean energy policy should drive forward the development of new, cost-effective technologies. As a national leader in wind, as well as energy efficiency and renewable choice programs, we are optimistic about the future opportunities that clean energy technologies present. Additionally, we are committed to owning these resources to improve the overall value and cost savings to our customers and stakeholders.
- **Efficiency and cost effectiveness.** The most efficient and effective response to environmental mandates is not always stack-by-stack or emission-specific compliance requirements. In some cases, compliance should be coordinated on a system-wide basis to maximize cost effectiveness and environmental benefits.
- **Flexibility.** Flexibility mechanisms, such as alternative compliance options and market-based environmental programs, should be incorporated into environmental rules. Flexibility yields real cost benefits to customers while maintaining environmental benefits.

Environmental Management System

We have a comprehensive environmental management system designed to promote environmental excellence and ensure continuous improvement and compliance with all applicable environmental requirements. Although we have not used formal certification under ISO 14001, our environmental management system aligns with and enables the nine elements of the ISO 14001 standard, including: policies, responsibilities, environmental interaction, impacts, compliance, objectives and targets, monitoring and measurement, performance review and continuous improvement.

Our management system provides:

Oversight	Board of Directors — Operations, Nuclear, Environmental and Safety Committee
	Chairman, president and CEO
	Executive Committee
	Environmental Policy department
	Environmental Services department
Risk analysis	Goals and performance indicators at corporate and operating levels
	Multidisciplinary teams for developing new compliance programs
	Environmental Audit program
	Regular risk assessments
Policies & procedures	Corporate environmental policy
	Formal, documented processes, procedures and standards
	Routine monitoring of new, evolving regulatory activity

Monitoring	Centralized and automated compliance tracking system that uses real-time data
	Monthly performance reporting
	Routine facility audits
Follow-up for compliance gaps	Tracking for corrective action and internal audit findings
Training and communication	New employee orientation
	Site and topic specific employee training and tracking
	Updates and information communicated through internal channels

Compliance Results

We strive to operate in compliance with all federal, state and local rules and regulations. However, there are occasions when regulatory agencies issue notices of violation (NOVs) or other types of notifications of potential noncompliance for alleged exceedances of permit limits or regulatory requirements. These NOVs can result in fines or penalties. Often there can be disputes about the alleged noncompliance, and even when it is our view that we remained in compliance, settlements are often reached to avoid the transaction costs of litigation and to cooperate with the regulatory agencies.

Every year as part of our internal and ongoing efforts to self-identify and self-correct any potential noncompliance issues, we conduct our own facility audits.

2018 Compliance Activity

Activity*	2016	2017	2018
Notices of Violation or Compliance Advisories	4	7	5
Penalties Paid	$25,000	$14,949	$0
External Agency Audits or Inspections	83	64	71
Internal Audits Conducted to Ensure Compliance	99	95	94

*Because of the regulatory process and timing, penalties are not typically paid in the same year that Notices of Violation or Compliance Advisories are issued.

We received five notices of violation or compliance advisories in 2018 involving activities at our facilities. All were considered minor infractions and no penalties or fines have been assessed. Of the five incidents, two involved wastewater discharges and the others related to air emissions testing, drinking water sampling and regulated waste storage.

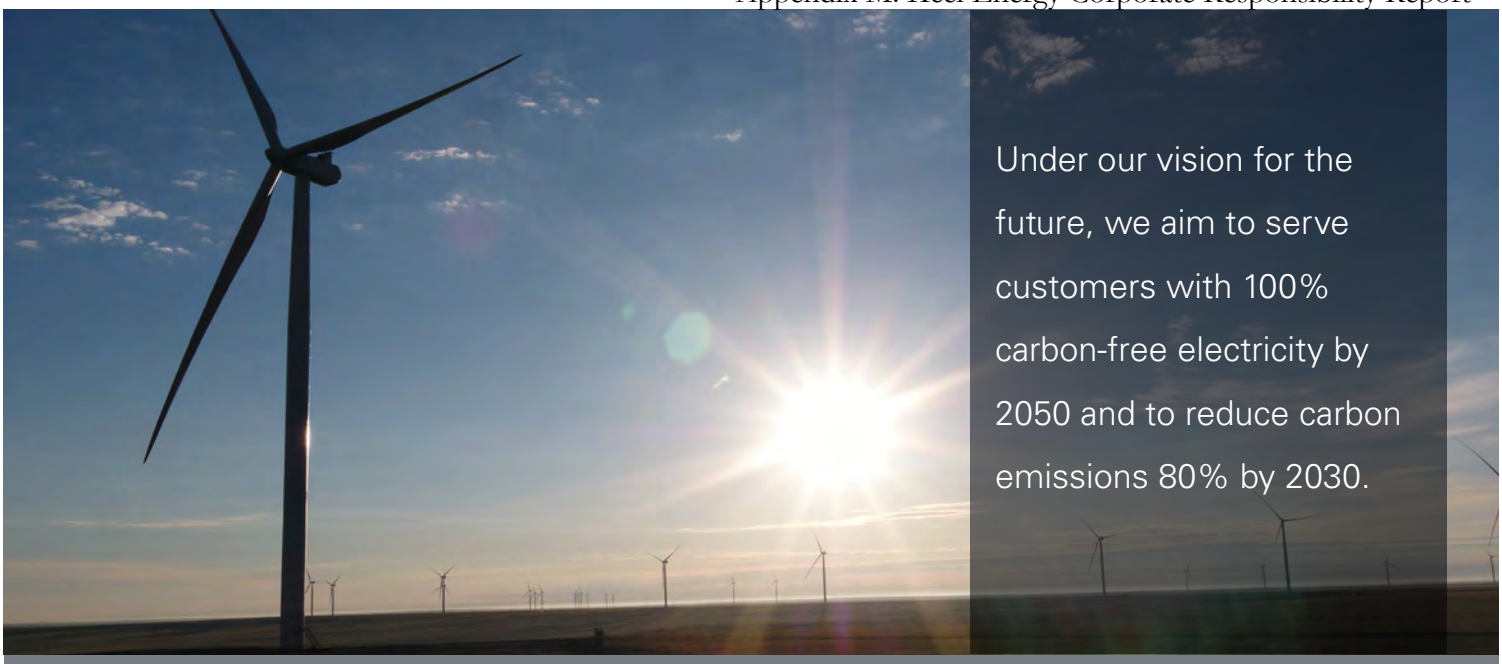
Environmental Expenditures

Environmental costs include payments for nuclear plant decommissioning, storage and ultimate disposal of spent nuclear fuel, disposal of hazardous materials and waste, remediation of contaminated sites and monitoring of discharges to the environment. As we have reduced emissions through the addition of environmental controls, the total costs of investing in and operating the controls has risen somewhat over time.

Environmental Expenditures

Expenditure Type	2016	2017	2018
Operating and Maintenance	$304	$303	$309
Capital	$93	$61	$50

More detailed information regarding nuclear decommissioning and spent nuclear fuel disposal expenses is provided in our 2018 Form 10-K.



Climate change and greenhouse gas emissions

A carbon-free future

Energy is an essential service that powers the economy and provides comfort and security. As we lead the clean energy transition, we will ensure that customers have energy when they need it, at an affordable price.

We know that climate change is an urgent issue for many of our policy makers and investors and is a growing concern of our customers who want to help make a difference. It is a priority for us as well, and is the reason we were the first major energy company in the nation to announce a vision to serve customers with 100% carbon-free electricity.

Planning for this transition to a clean energy future today will allow us to deliver the products our customers want and achieve reductions that our policy makers and investors are increasingly demanding. By acting now, we increase our ability to achieve our goals while assuring that our system remains reliable and our energy service affordable.

2018 Results

- We established our bold, new vision to provide customers with 100% carbon-free electricity by 2050 and to reduce carbon emissions 80% by 2030 from the electricity that serves our customers. To successfully make this transition, we must also maintain the reliable, affordable energy that customers expect.
- Climate modeling experts from the University of Denver, led by a lead author for the Intergovernmental Panel on Climate Change, analyzed our carbon goals and concluded they are consistent with electric sector emissions in scenarios likely to achieve the temperature targets of the Paris climate agreement.

- Our carbon emissions continue to decline. Since 2005, we have decreased carbon emissions 38% from electricity that serves our customers — an additional 3% reduction compared to 2017 levels. Our reduction levels surpass the U.S. commitment under the Paris climate agreement, which called for a 26% to 28% reduction in carbon emissions by 2025, and the EPA Clean Power Plan, which would have reduced carbon emissions 32% by 2030.
- For 13 consecutive years, our carbon reporting has been third-party verified in accordance with The Climate Registry — we are the only electric utility with this length of consecutive verified data.
- Since Xcel Energy became a member of EPA's Natural Gas STAR program in 2008, we have reduced methane emissions by more than 350 million cubic feet while expanding our miles of pipe 6%.

Our Pathway to a Carbon-free Future

As we produce energy to serve our customers, we emit greenhouse gases. Our primary source of these emissions is from the combustion of fossil fuels to generate electricity, which makes up 99% of our total greenhouse gas emissions. Nearly all of our generation-related emissions are carbon dioxide. Because of this, it makes sense that our clean energy strategy focus primarily on reducing carbon emissions from electricity.

To achieve our carbon vision, we will continue working with our states and stakeholders. Our interim goal to reduce carbon emissions 80% by 2030 is based on absolute, company-wide emissions from the electricity that serves our retail and wholesale customers, measured from a 2005 baseline. Likewise, our aspiration to serve customers with carbon-free electricity by 2050 is company-wide.

Currently, we are implementing plans to achieve our previous goal to reduce carbon emissions 60% by 2030, from 2005 levels. Our state regulatory commissions have already approved the following efforts underway:

- The Colorado Energy Plan, which calls for the early retirement of 660 megawatts of coal-fueled generation by 2026 and the addition of 1,100 megawatts wind, 700 megawatts solar, 380 megawatts existing natural gas and 275 megawatts large-scale battery storage.
- Our current 2016 to 2030 Minnesota Resource Plan, which increases renewables in the Upper Midwest and retires nearly 1,400 megawatts of coal-fueled generation by 2026. A new resource plan for the region will be proposed in summer 2019.
- Our multi-state wind expansion announced in 2017 that will add nearly 3,700 megawatts of wind energy from 12 new projects across seven states.

We also are working on plans that take us all the way to reduce carbon emissions 80%. This is not a single plan, but will happen through a series of resource plans to be approved through our state regulatory processes.

In setting our goals, we did sensitivity analysis to identify key elements and variables that could affect our plans for reaching the interim goal. There are a variety of cost-effective pathways to reduce carbon emissions 80% by 2030, and we know the following common elements will be part of the plans:

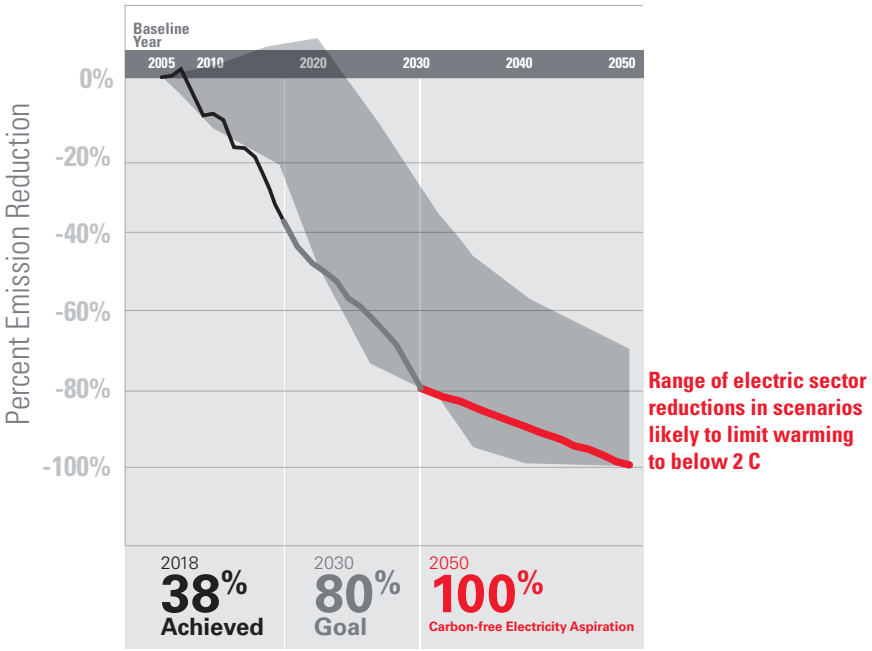
- Adding thousands of megawatts of wind and solar power to our system
- Incorporating both natural gas and storage resources to help balance high levels of renewable energy
- Deploying strategic electrification of certain end uses to help create flexible demand
- Continuing to implement industry-leading energy efficiency programs
- Seeking to operate our nuclear plants through at least the remainder of their licenses
- Retiring additional coal units or changing their operations to minimize emissions affordably and reliably
- Investing in supportive infrastructure to modernize the power grid

Looking beyond 2030 to our 2050 carbon-free aspiration, we will need new, 24/7 carbon-free technologies that are not yet commercially available at the cost and scale needed. These are technologies that can integrate high levels of renewables, balancing the peaks when customer use exceeds renewable generation and valleys when renewable generation exceeds customer use. To ensure these technologies are ready when we need them at an affordable price, there must be more research, innovation and development. Technology advancement is key to the long-term success of our strategy, and it has a long lead time for development.

Scientific Analysis

The most recent climate science informed our carbon vision, which is designed to minimize the long-term risks associated with climate change. After reviewing international and national climate reports released in 2018, we hired an IPCC lead author and other climate modeling experts with the University of Denver to understand how our vision relates to global temperature goals. They consulted the newest International Panel on Climate Change emission scenarios database and analyzed carbon emissions for the electric sector in industrialized countries, within the scenarios that have a high (66% or greater) probability of achieving the 2 C goal and those more likely than not (50% or greater) to achieve the 1.5 C goal.

Xcel Energy's carbon goals align with scenarios likely to limit warming to 2 C.



The dark gray shaded area in the chart above represents the range from the highest to the lowest of these emission scenarios. The climate modeling experts then compared Xcel Energy's carbon emission reduction trajectory, including carbon reductions to date and the 2030 and 2050 goals. Based on their analysis, our reduction targets are clearly consistent with — even on the low end of — the electric sector reductions in scenarios that achieve the international 2 C goal. Even more encouraging, this analysis shows that our emission trajectory is also consistent with the more aggressive 1.5 C goal.

Driving Change

We believe reducing carbon emissions reliably and affordably must be the top priority of our clean energy transition. To achieve this, we need to be disciplined and focus on efforts that will produce the greatest carbon reductions at the lowest cost to customers.

We have identified the following drivers that will make the change possible:

- **Protect energy reliability and affordability.** Our goals rely on maintaining these service fundamentals and cannot be achieved without them.
- **Support from our states and stakeholders.** We will need the support of stakeholders and state regulators to implement the resource plans that will achieve our goals.
- **A constructive policy environment and framework.** Reducing carbon emissions at the lowest cost should be the policy objective. To that end, we are advocating for policies that encourage economical large-scale clean energy development and utility ownership of resources.
- **Availability of cost-effective, carbon-free, 24/7 technologies.** There must be research and development to advance clean energy technologies, beyond renewables. We will need these technologies to eliminate the last 20% of carbon from the electricity serving our customers.

While our vision is ambitious, we believe these drivers implemented together will make it possible to transform our operations and the industry overall. Our plan is to continue working proactively and collaboratively in all these areas and to advance the solutions that emerge.

Energy and Carbon Emissions Reporting

Xcel Energy supports timely, transparent public reporting of carbon dioxide and other greenhouse gas emissions. Our comprehensive greenhouse gas reporting, from all parts of our business, is based on The Climate Registry and its Electric Power Sector Protocol, which aligns with the World Resources Institute and ISO 14000 series standards.

We joined The Climate Registry as a founding member in 2007 to help establish a consistent and transparent standard for calculating, verifying and reporting greenhouse gases. Through The Climate Registry, we annually third-party verify, register and publicly disclose our greenhouse gas emissions.

We report carbon emissions from electric generating plants that we own and from electricity that we purchase from others. We sell a small portion of the electricity we generate into the market to retailers outside our service territory. The carbon emissions from these off-system sales are excluded from our goal and associated carbon reporting because the energy does not serve our customers. Also, it is likely that companies purchasing the energy account for the emissions in their reporting, so excluding the carbon emissions associated with off-system sales from our reporting avoids double counting.

Our progress toward a carbon-free future.

Methane Emissions

Our efforts to reduce greenhouse gas emissions also include methane emissions — a primary concern for the natural gas value chain. We are actively involved in programs that work to address the supply, midstream, distribution and consumer use of natural gas that are important to maintaining the industry's ability to operate. Xcel Energy serves about 2 million customers with natural gas for heating and other energy uses critical to the colder parts of our territory, Colorado and Minnesota, and does so with minimal methane emissions.

Methane emissions make up a small part of our total greenhouse emissions — less than 1% of our total greenhouse gas emissions (190,249 metric tons CO_2e) in 2018. Nevertheless, we strive to operate the cleanest distribution system possible and minimize our methane emissions through cost-effective improvements to our natural gas system.

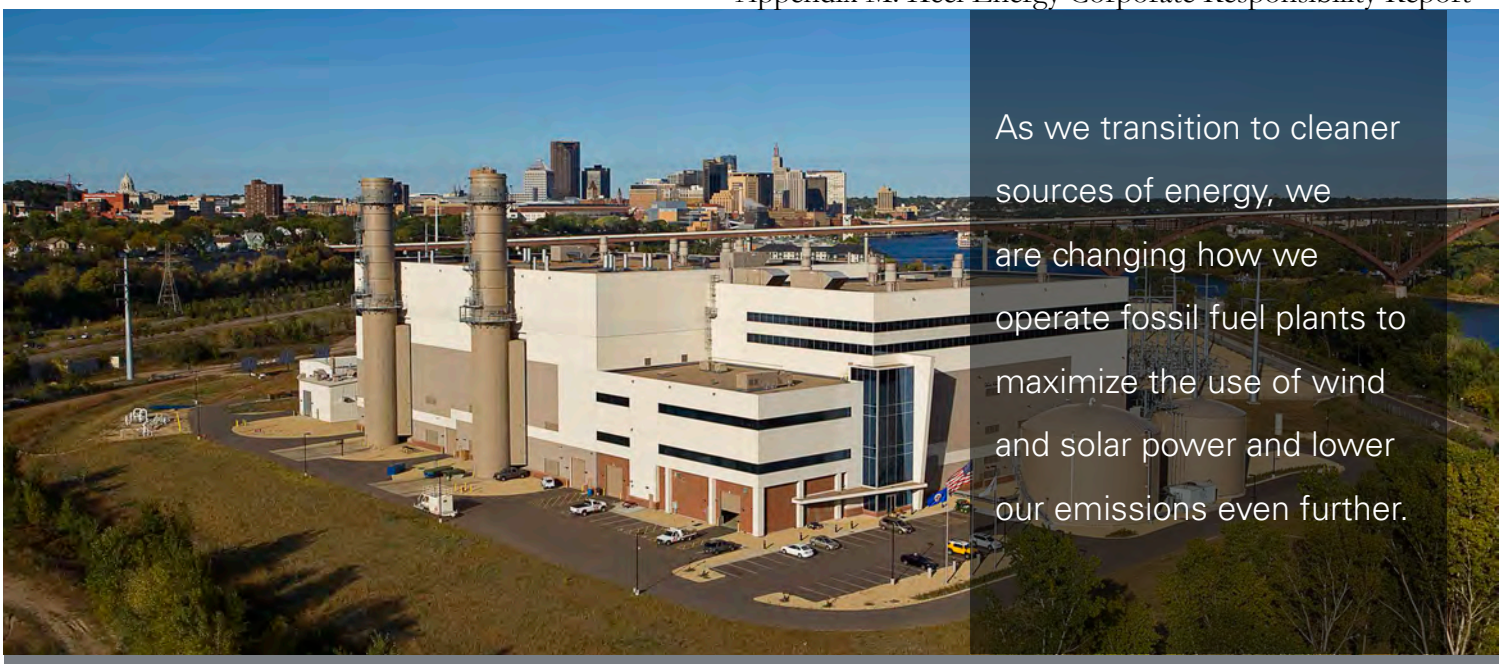
We have achieved these reductions through voluntary efforts. Since 2008, we have participated in EPA's Natural Gas STAR program, and we are a founding member of the program's Methane Challenge launched in 2016. Through the Methane Challenge, we plan to reduce methane releases more than 50% from the venting of pipelines during scheduled construction. We are also investing in operational improvements that not only reduce methane emissions but improve the overall safety and efficiency of the natural gas system for customers. These improvements include:

- **Replacing the cast iron pipe and unprotected steel pipe on our system, originally installed 50 to 100 years ago.** We replaced all 880 miles of cast iron pipe and have regulatory approval to continue removing bare-steel pipe from our system over the next five years.
- **Using pressure reductions and other methods to reduce methane emissions during pipeline maintenance and repairs.** We reduced our emissions from blowdowns on systems operating at excess of 60 psig by 89%, therefore, avoiding the release of 24 million cubic feet of gas into the atmosphere.
- **Replacing high-bleed controllers on our distribution and high-pressure pipelines.** We are currently working to replace the high-bleed controllers in our processing plants and are considering new programs to modernize the high-bleed controllers at our storage fields and compressor stations to reduce emissions at these facilities.

In addition to these programs, we are collaborating within the natural gas industry on initiatives that support our own proactive approach to operating and maintaining a natural gas system. For example, we are members of the Natural Gas Downstream Initiative, a collaborative effort with other major gas utilities, facilitated by MJ Bradley & Associates, focused on addressing the regulatory and technical issues related to the role of natural gas in a low-carbon future.

Beyond our direct distribution operations, we also recognize that the majority of greenhouse gas emissions associated with natural gas is in other parts of the value chain. This includes methane emissions from upstream sources through the production, compression and long-distance transmission of natural gas, and carbon emissions from downstream, end-use consumers. We participate in the Natural Gas Supply Collaborative, a group of natural gas producers calling for transparency and sustainability from upstream suppliers. Our industry associations, the American Gas Association and the Edison Electric Institute, are also partnering to understand methane emissions and enhance disclosures across the value chain.

For our customers who use natural gas, we are exploring opportunities to offer low-carbon solutions. We already provide a comprehensive portfolio of natural gas efficiency programs, but are exploring new technologies and methods to help our customers further reduce their carbon footprints. We see great potential for renewable natural gas to provide a lower carbon alternative and the potential for targeted, strategic electrification, such as water heaters, that could be powered with clean, renewable energy. As always, we are monitoring long-term technologies, such as hydrogen or power-to-gas, which could fundamentally shift natural gas supply and related carbon emissions.



Air quality

Reducing air and other emissions

With support from stakeholders and regulators, we are voluntarily retiring half of our coal-fueled capacity by 2026 — a step that will significantly reduce emissions.

Our largest source of air and other emissions is the combustion of fossil fuels to generate electricity, primarily from coal. For well over half a century, coal has been a steady source of low-cost, dependable electricity for our customers that we have carefully controlled and operated in an environmentally responsible manner.

Since the 1990s, we have worked with our states and other local stakeholders on proactive environmental projects that serve as a national model for addressing state air quality needs while providing operational flexibility and ensuring reliable, affordable energy for customers. We know that clean air and cleaner energy are priorities for the customers and communities we serve, and as a leader in this field, they continue to be our priorities too.

As the cost to generate electricity with natural gas and renewable sources declines and these technologies improve, the way we generate electricity is becoming progressively cleaner. We are moving away from coal to lead the transition to clean energy, especially now as we work to achieve our vision to serve customers with 100% carbon-free electricity by 2050. To fulfill this commitment, we plan to rely on the relationships we have built and our successful model for engaging stakeholders to find new solutions — solutions that will not only cut carbon, but have the added benefit of reducing other emissions and improving the environment overall.

2018 Results

- Since 2005, we have reduced carbon emissions 38% from the electricity that serves customers.
- We continued to decrease emissions of sulfur dioxide, nitrogen oxides, mercury and particulate matter to levels that were 77%, 78%, 91% and 73% lower, compared to 2005.
- Under the EPA's Toxic Release Inventory program, we have reduced releases by nearly 30%, compared to 2005 levels.

- The Colorado Department of Public Health and Environment through its Environmental Leadership Program recognized Xcel Energy as a Gold Leader for the company's comprehensive Environmental Management System as well as its clean energy leadership and environmental stewardship.
- Within our vehicle fleet, we essentially replace all sedans scheduled for retirement with electric vehicles. We estimate that our 43 plug-in hybrid electric vehicles (PHEVs) helped to avoid emission of nearly 92 metric tons of carbon emissions for the year.

Maximizing System Operations to Reduce Emissions

There is a significant shift in how we operate our power grid now compared to several decades ago. Not only are we changing the way we produce electricity, but the dispatch and operation of our generating resources is different too.

Through major clean energy initiatives in Colorado and Minnesota, we have retired coal units and replaced the power with cleaner, more flexible natural gas and wind and solar generation, and we have plans to do more. Last year, regulators approved our new Colorado Energy Plan that will retire two coal units and add thousands of megawatts of new wind, solar and battery storage, as well as existing natural gas. We also have approval to retire two coal units in Minnesota by 2026, and are moving forward with our multi-state wind initiative with 12 new wind farms to be completed in 2021.

As renewable energy gradually becomes the majority energy source on our system, we are focusing our operations to follow the wind and sun to maximize clean electricity production and do so reliably and cost effectively.

Advanced forecasting tools have dramatically improved the predictability of wind energy, making a variable energy source much more dependable. With reliable wind forecasts now available seven days in advance, we are able to make more accurate commitment and dispatch decisions associated with wind energy. Cleaner natural gas generation is an excellent companion to renewable generation. It has long managed the variability of wind-power production, with natural gas units cycling up and down as needed to help meet electric loads as wind speeds rise and fall.

Several years ago, an Xcel Energy operations team began exploring how coal units could do the same, although ramping up and down coal units is much more challenging. Traditionally, coal units have provided baseload power for our system, with the capability to run dependably 24/7. The company's coal plants began testing and learning their limitations, working around problems at lower load points and figuring out how to overcome them.

Today, this reduction in coal operations is creating additional system flexibility and helping to advance our transition to clean energy while reducing emissions and saving customers money. In 2018, our efforts to turn down and cycle off these units reduced coal generation by more than 788,000 megawatt hours, saving an estimated $1.6 million and avoiding approximately 886,000 tons of carbon dioxide, as well as other emissions.

Reducing Fleet Vehicle Emissions

Our fleet of about 7,000 vehicles includes everything from small cars to light trucks, bucket trucks, excavators and trailers. In 2014, our vehicles were equipped with telematics to reduce fuel costs and improve driver safety. Using the technology has reduced idling and fuel consumption, wear and tear on vehicles, and emissions. In 2018, we estimate that the use of telematics saved approximately 150,000 gallons of fuel at a value of more than $350,000.

Community Right to Know and the Toxic Release Inventory Program

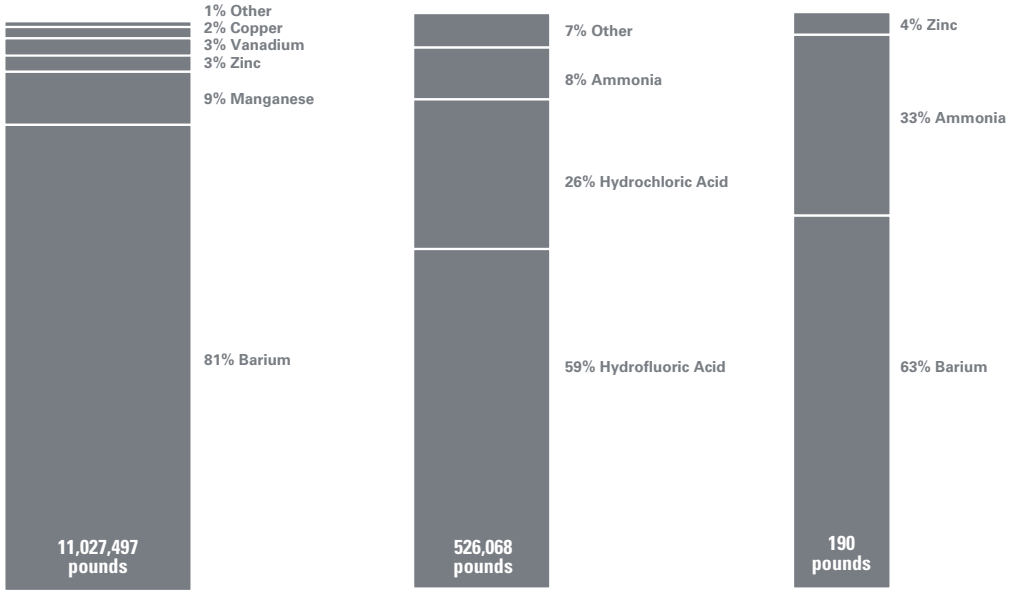
The EPA has administered the Emergency Planning and Community-Right-to-Know Act or EPCRA since 1986. The program is intended to help communities protect residents from potential chemical hazards. Under EPCRA, residents have the "right-to-know" about chemicals in their communities. Each year facilities in specific industries that manufacture, process or use the nearly 650 substances identified under the program must report their releases to air, land and water. The EPA manages the information in a publicly available database under the Toxic Release Inventory (TRI) program.

Xcel Energy supports this type of reporting and has participated since 1999 when the program was expanded to include electric utilities. We annually report to EPA our releases, which are the result of using coal, oil and refuse-derived fuel (processed municipal solid waste) to produce electricity. When these fuels are combusted, they release trace amounts of TRI reportable substances, including barium, chromium, copper, lead, manganese, mercury, nickel and zinc.

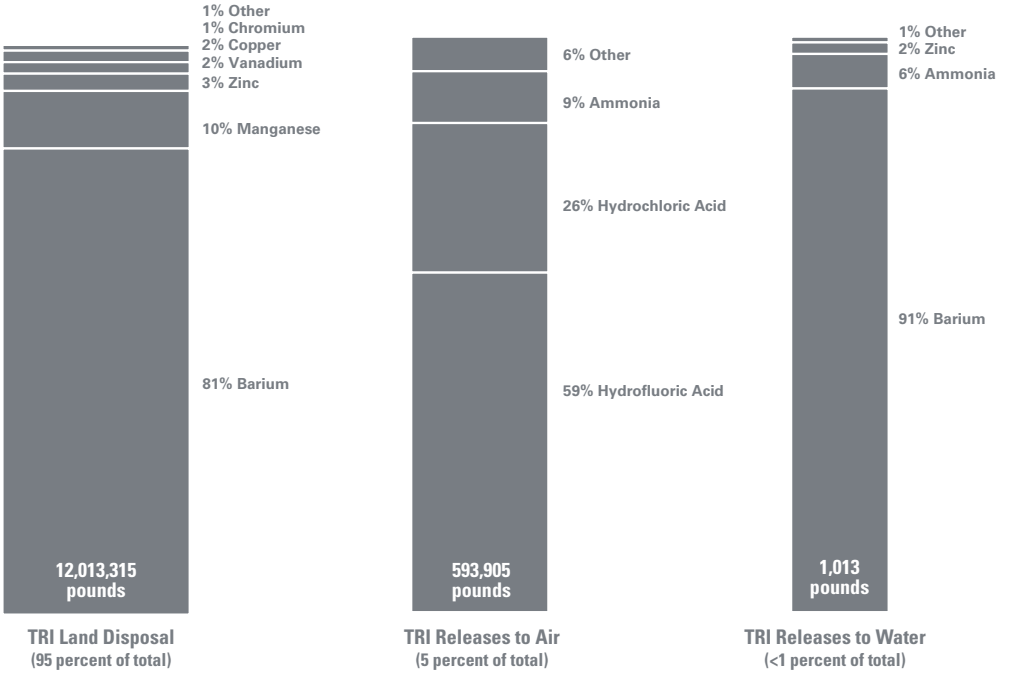
TRI reportable substances are reported by facility and release type — land, air and water. A facility's releases may change slightly from year to year based on the amount of electricity produced and the associated fuel that is consumed, as well as the fuel composition and mineralogy.

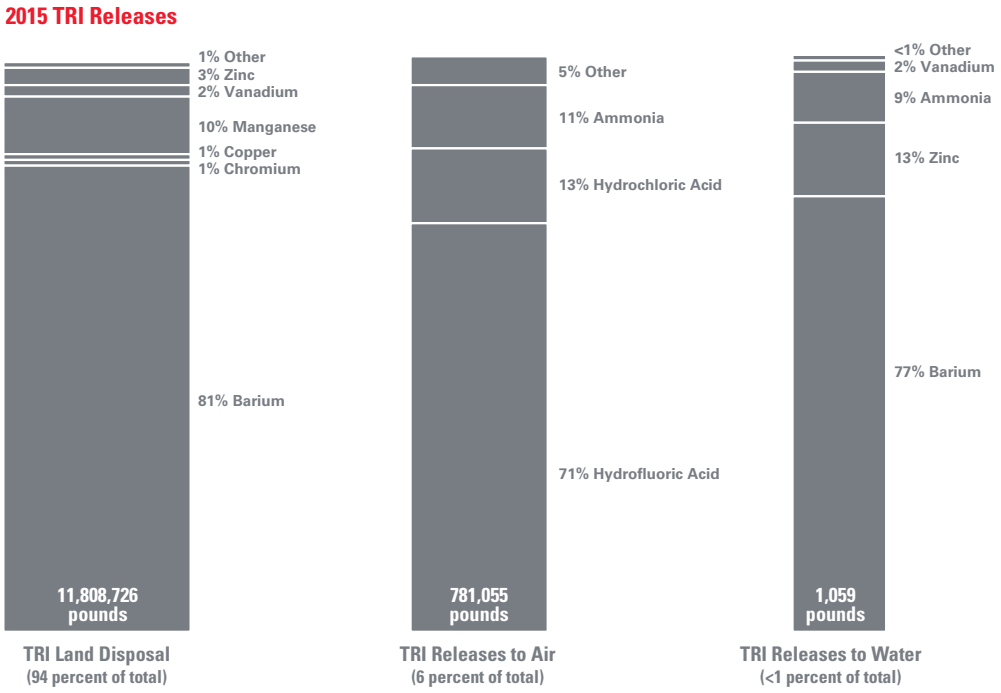
The vast majority of our TRI reportable substances are controlled at our facilities as part of the coal ash where they are contained, preventing them from entering the air. We capture about 95% of these substances and safely dispose of them in managed landfills.

2017 TRI Releases

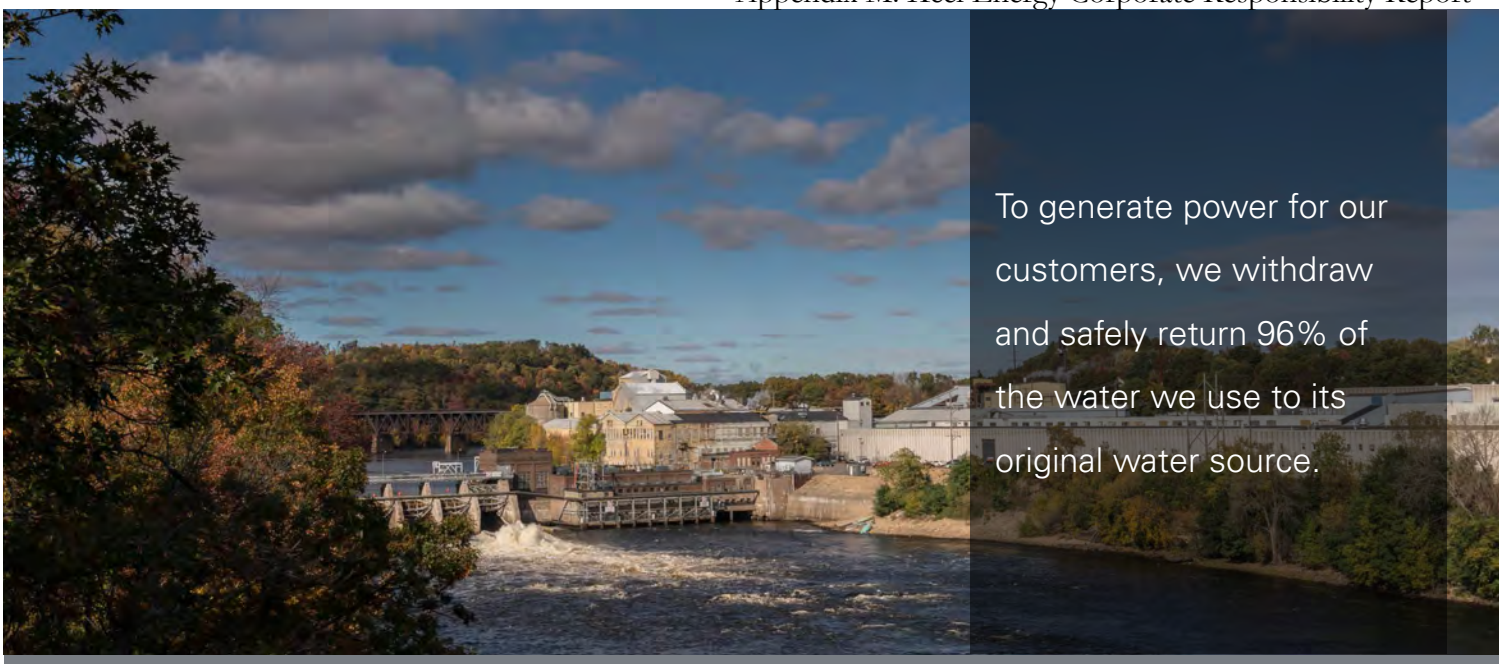


2016 TRI Releases





Releases provided here are from 11 generating plants in locations throughout our service territory. For individual plant information visit the EPA's TRI Explorer website or contact corporateresponsibility@xcelenergy.com.



Water quality, availability and management

Managing water use

We regularly collaborate with local stakeholders and water managers on innovative partnerships and agreements to ensure reliable, cost-effective water supplies for our operations while also addressing different community needs.

Water conservation and protecting water quality are priorities for us. In the more arid Western and Southwestern regions where we operate, conserving and managing our water supply is especially important given challenges we face in dry years and concerns over drought. In all regions, we continually evaluate and monitor our systems and processes to ensure the water we return to local waterways is safe and meets the discharge limits contained in our Clean Water Act permits.

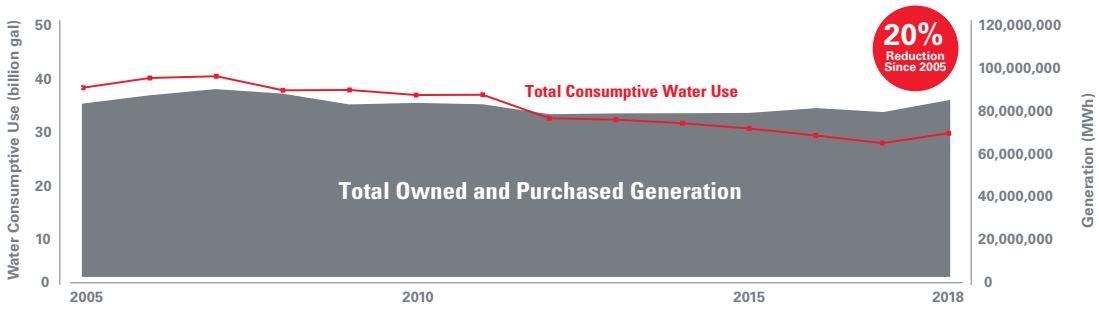
We understand that water is a fundamental, shared resource and is vital to the growth and development of our communities and to other industries, agriculture and ecosystems. As competition for water increases and weather patterns change, our water resources will become more stressed. That is why we continue to work cooperatively with our communities and states to secure responsible supply options and to save fresh water where we can.

2018 Results

- Water powers steam turbines and cools equipment at thermal electric generating plants. Our thermal plants in Colorado, Texas and New Mexico use closed-loop cooling which requires less water to operate efficiently and minimizes fresh water withdrawals by recirculating water multiple times within the system — up to 25 times at some plants.
- From 2005 to 2018, we reduced water consumption approximately 20% from the electricity we generate and purchase, while total electricity production remained generally the same over that period. We expect water consumption to continue to decrease as we retire additional coal units and rely more on wind and solar resources that require no water to produce electricity.

- We withdrew approximately 638 billion gallons of water during the year, including municipal wastewater or effluent, to generate electricity at our thermal electric and hydroelectric generating plants. From these withdrawals, our facilities consumed approximately 24 billion gallons of water and returned approximately 614 billion gallons (96%) to the original water source.
- Our Upper Midwest thermal plants use open-loop cooling where water is continuously withdrawn and directly returned. Although water withdrawals are higher with this type of cooling system, consumption is lower. Our plants with open-loop cooling systems return about 99% of the water they withdraw to its original source.
- Over the past 38 years, we have saved about 200 billion gallons of freshwater by pioneering the use of treated municipal effluent to cool the Nichols-Harrington and Jones generating plants in Texas — enough water to fill nearby Lake Meredith and then some.
- The Xcel Energy Foundation contributed more than $135,000 through its environmental stewardship focus area to nonprofit programs that support water quality, education and riparian restoration efforts. For several years, the foundation has supported the restoration work of RiversEdge West and its DesertRivers Collaborative. The program supports local land managers and efforts to restore riparian areas along the Colorado River in the Grand Valley region of Colorado and the lower Gunnison River. In Minnesota, we are a longstanding supporter of Friends of the Mississippi and currently fund its Community Stewards program. Working with agency staff, volunteers and local partners, the organization held 35 stewardship events for the year at different sites along the river.

Xcel Energy water consumption compared to electricity supply from owned and purchased generation.



Managing Water Supply

Thermal Operations in the West and Southwest

In the semi-arid and arid states where we operate — Colorado, New Mexico and Texas — we have strategic water resource plans that are updated annually to reflect our current operational requirements, local climate conditions and water use. Throughout the year we conduct a variety of activities to accurately predict and plan for future water supplies, which include:

- Forecasting plant water requirements based on anticipated electric generation
- Accounting for the water we need and use
- Monitoring snowpack reports
- Studying stream flow forecasts, seasonal climate projections and changes to the Ogallala aquifer — the primary aquifer that underlies much of the region in Texas and New Mexico that we serve

We acquire water for our thermal and hydroelectric plants through water rights and other agreements Our integrated portfolio of water supply resources includes owned or self-supplied water rights, reservoir storage, groundwater rights and a number of other supplies, such as municipal and recycled water supplies. We own water supplies dedicated for our own use, and in Colorado, these water rights are available depending on regional water supply conditions in accordance with the state's prior appropriation system. Our portfolio also includes water from geographically diverse areas, including trans-basin water imported from other basins. This diversity is critical for maintaining a resilient, reliable water supply in the arid, climatically variable western United States.

We have expended significant resources to improve our water supply and the resiliency of our systems. Other suppliers that we do business with have responded similarly, taking steps to improve their water supplies and adopt drought response plans for ensuring they meet their municipal and industrial water supply obligations. Further, they pursued the acquisition of geographically diverse water supplies originating in other river basins, enhancing the resiliency of their systems.

Finally, we use recycled water or treated municipal effluent where available and feasible, which minimizes the competition between water needs for power generation and needs for environmental, recreational, municipal or other industrial uses. Recycled water use has the added benefit of increasing the reliability of our water supply because it is virtually drought proof and preserves billions of gallons of fresh water.

Thermal Operations in the Upper Midwest

In Minnesota and Wisconsin where we operate thermal plants, water is more abundant and these facilities are permitted to withdraw and return water to nearby rivers and other waterways. While this helps to minimize water consumption, we still take a strategic approach to water use in these areas by monitoring weather patterns and using meteorological forecasting models to predict and ensure an adequate water supply during times when unusually dry conditions are likely to persist.

During these rare dry periods or drought years, we evaluate the use of alternative cooling options for each facility and implement prudent, temporary measures to provide supplemental thermal cooling. In times of energy emergencies, our permits have provisions that allow some plant operating flexibility, along with additional environmental monitoring requirements to ensure the protection of fish and other aquatic life.

2018 Water Use by Source (Billions of Gallons)

Source	Withdrawn	Consumed	Returned
South Platte River Basin	*5.18	4.48	0.70
Arkansas River Basin	*4.56	3.72	0.84
Yampa River Basin	1.32	1.32	0.00

*Includes transbasin diversions

**Does not include groundwater from these locations

Hydroelectric Operations

Xcel Energy operates 26 hydroelectric plants, including six in Colorado, one in Minnesota and 19 in Wisconsin, with enough capacity to power more than 280,000 homes. Although these plants use water to produce electricity, the only water loss is through natural evaporation from reservoirs. We work with environmental and wildlife agencies to ensure plans are in place for monitoring watering quality, protecting aquatic life, ensuring minimum stream flow, preventing erosion, and controlling noxious weeds and other invasive plants. Many of our hydroelectric plants offer public recreational opportunities and some are stocked with fish.

Xcel Energy's hydroelectric plants operate on the following waterways; many of these are open to public recreation:

2018 Water Use by Source (billions of gallons)

Colorado	Minnesota	Wisconsin
Lower Clear Creek	Mississippi River	Chippewa River
South Fork Arkansas River		Apple River
South Clear Creek		Red Cedar River
Colorado River		Namekagon River
Animas River and tributaries		Montreal River
San Miguel River and tributaries		White River
		Flambeau River
		St. Croix River

Meeting Mutual Water Needs

Planning for and managing future water supply is essential for the states and communities we serve. We actively participate in these efforts to provide our expertise and solutions, as well as to plan for our own water needs. The following are examples of our engagement and some of the innovative partnerships and agreements we have in place.

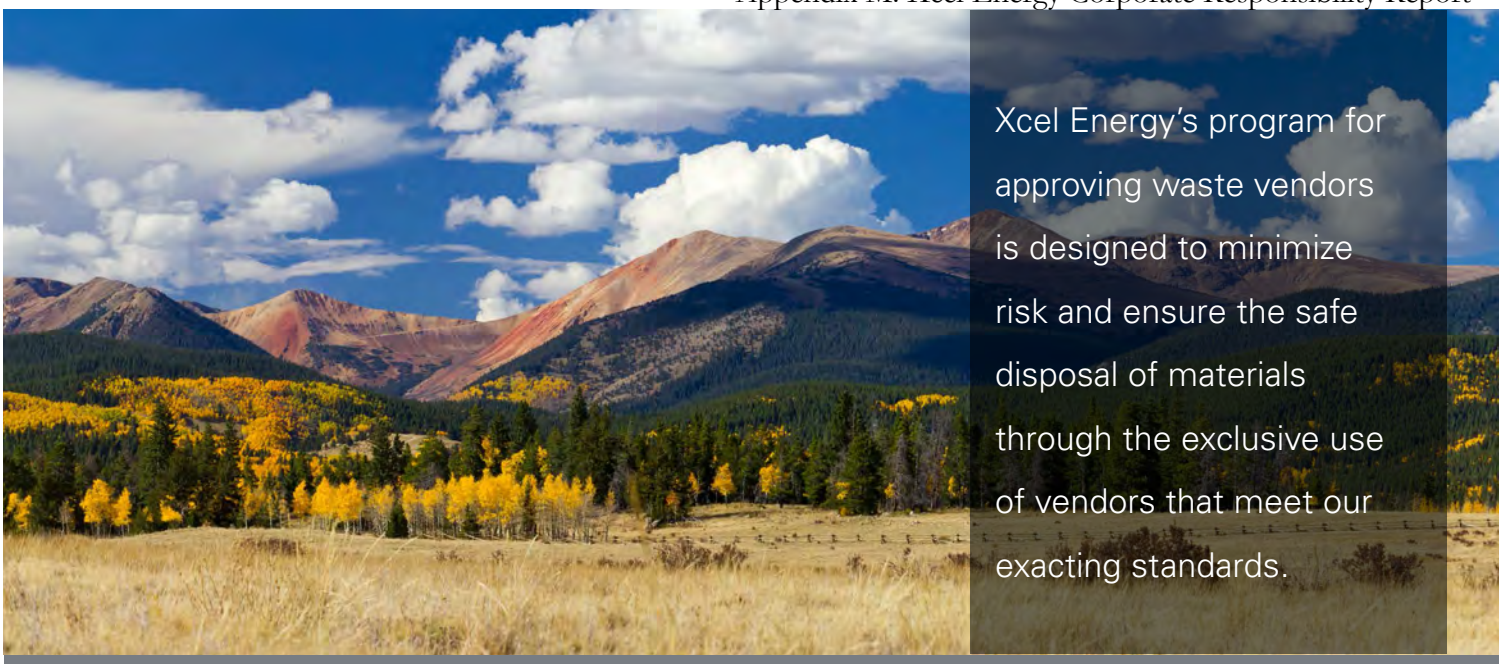
- Our Water Resources staff is actively engaged in the ongoing Colorado Water Plan process. They participate on volunteer boards and technical working groups, serve on the board of water user groups working to meet Colorado's obligations under Endangered Species Recovery programs, and participate in other water user groups working to craft policy and legislation to better adapt Colorado's water supplies to changing conditions. For decades, they have served on boards and as officers overseeing nine ditch companies in Colorado where the company owns significant water rights. Through these organizations, conflicts involving water are often identified and amicably resolved.
- We own very senior water rights on the Colorado River that are used to operate the Shoshone Hydroelectric Generating Plant. To help meet water needs within the city of Denver, along the Front Range and for some users on the Western slope, we established an agreement in 2006 to "relax" a portion of our water requirements for Shoshone during dry years. Colorado experienced below-average moisture in 2013, which is the most recent year that we executed on the agreement. We reduced Shoshone's water use by more than half and allowed water to be stored for critical uses, benefitting users throughout the state.

- We have agreements with the cities of Longmont and Westminster in Colorado to exchange high quality water under our water rights with their lowest quality water or effluent, which we use at our area power plants. It's similar to a practice we pioneered in Texas where we use recycled municipal effluent for cooling at our power plants.
- In dry years, Colorado farmers typically lack the full water supply needed to produce marketable crops. Through a mutually beneficial agreement, we buy limited quantities of water that farmers have available and use it in our power plants. Under this arrangement, farmers are compensated, helping them financially during dry years.
- In the Southwest, our Water Resources staff serves on regional groundwater planning committees to better manage critical resources like the Ogallala Aquifer which is the region's primary water supply and underlies much of our service area.
- Xcel Energy is a member of the Minnesota Sustainable Growth Coalition, a business-led partnership of 33 businesses and organizations working to promote a circular economy in the state. The coalition focuses on energy, water and waste issues to optimize use of resources, minimize waste and conserve resources. In the water area, the coalition is working on "greening gray infrastructure" or promoting infrastructure and practices designed to mimic the natural water cycle.

Maintaining Water Quality

All of our large plants in Texas and New Mexico, as well as several plants in Colorado, are zero-discharge facilities — no process water is discharged from the plant site. Instead, it can be reused for growing crops or disposed through evaporation ponds.

Other plants, especially those in Minnesota and Wisconsin, use once-through cooling where water is taken from a river or other waterway and returned to the environment. At all our plants where we return or discharge water, we systematically treat, monitor and analyze the water to ensure we are meeting discharge requirements and to protect fish and other aquatic life.



Waste management

Preventing and managing waste

We follow the same high standards outlined in our corporate environmental policy to responsibly reduce, reuse or dispose of our waste.

Our primary waste streams result from producing and delivering energy. This includes the coal ash that is left from burning coal to generate electricity, and the materials and equipment that come from the maintenance and repair of our transmission and distribution systems, as well as our natural gas system.

The best way to manage waste is to prevent it, and we have programs in place to help with this. We also look for opportunities to recycle or reuse waste as appropriate. When we must dispose of waste, we take steps to ensure that it is safely and properly disposed, which requires that our employees have the right training and follow the proper guidelines and procedures and that we use licensed facilities where applicable.

2018 Results

- We continue to reduce coal ash production as we transition to cleaner energy sources. Our generating plants produced 28% less coal ash for the year, compared to 2005.
- Approximately 19% of the coal ash our plants produced was reused. At our Texas generating plants, 100% of the coal ash is beneficially used, replacing products that would normally be produced from natural resources.
- We recycled nearly 23,000 tons of material from our operations, including more than 18,000 tons of wire and scrap metal.
- Altogether, we disposed of almost 10,000 tons of regulated waste from our operations, including 47 tons of hazardous waste.

Coal Ash Management

Coal-fueled generating plants produce coal combustion residuals or byproducts commonly referred to as coal ash. Xcel Energy's generating plants consumed about 23.2 million tons of coal in 2018, supplied from mines in Colorado and the Powder River Basin of Wyoming.

Our plants operate in states that have regulated coal ash for many years. We store and dispose of ash in impoundments or ponds and landfills in accordance with these regulations, which specify construction standards and operating requirements including routine inspections and groundwater monitoring.

The following are important facts about our coal ash management:

- More than half of our coal operations are in arid regions where groundwater is scarce or at a greater depth, a favorable geologic condition that mitigates the risks of impacts from ash storage or disposal.
- We reduced our number of coal ash repositories in 2018 by about 30%, from 13 to nine. We now manage three impoundments and six landfills. This is the result of shutting down coal units and actively removing ash impoundments that are no longer needed.
- Only 18% of the total ash our plants produced in 2018 was permanently disposed in impoundments.
- Our three active impoundments include a three-acre incised pond, a 17-acre bottom ash pond, and a 100-acre ash disposal impoundment. This larger impoundment is built to state-of-the-art standards and meets stringent safety requirements, according to an EPA inspection.

Throughout our system, we try to recycle coal ash whenever possible for beneficial use, such as in concrete products, roadbed material, soil stabilization, engineered-fill material and more. As we install and operate new emission controls at our plants, such as scrubbers and activated carbon for controlling mercury emissions, the ash composition changes, making it potentially less desirable for beneficial use.

Coal Ash Summary (estimated in tons)

	2016		2017		2018	
	Produced	Reused	Produced	Reused	Produced	Reused
Colorado	934,063	127,657	731,740	91,996	987,652	37,510
Southwest	274,785	274,785	289,391	289,391	207,092	207,092
Upper Midwest	699,401	55,982	649,662	43,531	775,237	121,675
TOTAL	1,908,249	458,424	1,670,793	424,918	1,969,981	366,277

EPA's Final Rule for Managing and Disposing Coal Ash

The final Coal Combustion Residuals Rule became effective in October 2015 and regulates coal ash as a non-hazardous waste under Subtitle D of the Resource Conservation and Recovery Act (RCRA-D). It establishes minimum national standards for the design, operation and closure of landfills and surface impoundments. Beneficial use of coal ash as defined under the regulation is exempted. Although it has undergone a number of changes since being enacted, Xcel Energy's facilities are well positioned to meet the rule's requirements without significant impact to operations and cost.

Our company completed our second annual groundwater monitoring reports required by the rule in January of 2019. We identified two sites in Colorado where there are impoundments or landfills present and where a statistically significant increase of certain constituents exists in the groundwater. However, at one of these locations, we have already removed the coal ash from the impoundment. Furthermore, the groundwater monitored at those two sites is directly adjacent to the impoundments or landfills and does not indicate any impact to local drinking water. We have

kept county officials informed of the situation, and are currently conducting additional groundwater sampling and initiating an assessment of corrective measures as prescribed by the rule to evaluate whether corrective action is required at these facilities. If applicable, we will be informing stakeholders on that process.

Waste Management

Xcel Energy's central Environmental Services department facilitates the company's waste management program, which is supported by facilities that generate regulated wastes. Environmental Services staff routinely visits these facilities and provides training and job aides to ensure facility personnel understand their waste management responsibilities. Our largest facilities have specific personnel trained to properly manage waste.

We have a program for approving waste vendors that is designed to minimize risk and ensure the safe disposal of materials through the exclusive use of vendors that meet our exacting standards. A team comprised of Environmental Services, Supply Chain, Legal, Risk Management and Investment Recovery employees meets quarterly to discuss the program and any relevant vendor issues. Vendors contracted to manage the higher risk wastes, such as hazardous waste, are audited on a routine basis.

Material Recycling and Reuse

We are committed to preventing pollution and reducing waste as part of our business planning and decision making processes. Some of our waste materials can be recycled, reused or may consist of parts and materials that can be reclaimed. Not only is the recovery of these materials good for the environment, but it also can help manage the cost of generating and delivering energy.

We began a major effort in 2016 to recycle "cobra head" style streetlights after launching a five-year project to replace these older lights with new energy-efficient LED fixtures throughout our territory. We are investing in the new technology to support the energy goals of the communities we serve and to reduce operating costs. The new LED fixtures use about 40% to 60% less electricity than high pressure sodium lights and have a longer operating life, which means fewer replacements and less maintenance.

We could have potentially sold the fixtures for reuse, but we agreed not to put these older, less efficient lights back on the street. Instead, we are recycling the lights after removing and properly disposing of environmentally sensitive components.

We will begin a multi-year project in 2019 to replace gas and electric meters as part of our Advanced Grid Intelligence and Security strategic initiative. Depending on regulatory and planning considerations, we could replace up to 5.5 million meters. We are developing a plan for managing and recycling the old meters as part of the sourcing effort for this project.

Global market conditions have negatively impacted the recyclables market, and in 2019, we saw a sharp decline in the market for recycled cardboard and plastic. We constantly look for viable and environmentally responsible recycling opportunities. The vendors that we choose to recycle these materials are selected by a competitive bid process. Waste recycling vendors that handle sensitive materials, such as oil and batteries, are reviewed using the same approved vendor process that is used for the disposal of wastes.

Material Recycling Summary (in Tons)

	2016	2017	2018
Cardboard		72	21
Batteries[1]		49	76
Plastic	53	72	2
Scrap metal	20,841	13,390	18,334
Used oil	3,609	3,635	4,320

1 Large lead-acid batteries recycled for reclaiming lead.

Waste Disposal

The waste we generate must be disposed at properly licensed facilities based on the waste type. All of the vendors that we contract to manage regulated wastes are part of our approved vendor program and are required to have a valid contract established in accordance with Xcel Energy's Supply Chain. The regulated wastes identified below are disposed at licensed facilities that have been vetted for financial viability, a positive compliance record and proper insurance.

The waste summary below generally represents normal operating conditions in 2018. In addition, we completed two significant environmental projects that resulted in the one-time generation of special wastes that are excluded from the totals below. We closed a water treatment pond at the Black Dog Generating Plant, which resulted in the disposal of 4,992 tons of coal and coal ash tainted sediments. We also completed remediation of a legacy manufactured gas plant site in Fargo, North Dakota that resulted in 46,000 tons of nonhazardous contaminated soils.

Waste Disposition Summary (in Tons)

	2016	2017	2018
Hazardous	31	50	47
Universal[1]	78	112	163
PCB related[2]	517	415	670
Asbestos	546	448	326
Special[3]	16,978	8,363	8,716

1 Universal waste includes regulated waste such as fluorescent light bulbs, rechargeable batteries and mercury switches.

2 PCBs (polychlorinated biphenyls) are chemicals controlled under the Toxic Substances Control Act. PCBs were historically used in transformer oil.

3 Special waste includes oily materials recovered from our operations, such as rags, filters, soil and water.

PCB Phase-out Effort

We have been phasing out PCB-containing equipment from our transmission and distribution system for many years. The Toxic Substances Control Act of 1979 defines PCB equipment as equipment containing oil having a PCB concentration of 500 parts per million (ppm) or more, while PCB-contaminated equipment has oil with a PCB concentration of 50 to 499 ppm.

Xcel Energy has made dedicated efforts to remove all known PCB equipment from its system, including transformers, capacitors and other regulated categories of equipment. This equipment was targeted, removed and replaced with non-PCB equipment.

Other phase-out efforts include the replacement of regulated equipment with non-PCB equipment as systems are upgraded. Any regulated equipment removed from the field is disposed of and replaced with non-PCB equipment unless there are extenuating circumstances associated with the design or procurement of the equipment. Xcel Energy personnel are trained on PCB regulations and the proper identification, handling, removal and disposal of this equipment to facilitate phase-out efforts. Aside from PCBs that are occasionally discovered during facility upgrade projects in small sealed or previously untested specialized equipment, most of the PCB and PCB-contaminated equipment left on our system is the result of cross-contamination occurring during manufacturing or maintenance activities prior to or shortly after the adoption of the Toxic Substances Control Act.

PCB Contaminated Equipment and Oil Removed from the Xcel Energy System

	2016	2017	2018
PCB and PCB-contaminated oil (gallons disposed)	21,378	36,632	33,311
PCB and PCB-contaminated equipment (units removed from service)	632	815	1,235

Legacy Manufactured Gas Plant Projects

In the late1800s until the mid-1900s, gas was manufactured using coal, oil and petroleum. It was used as natural gas is today, primarily for heating, cooking and street lighting. EPA estimates that thousands of manufactured gas plants or MGP facilities operated in the United States between 1815 and 1960. They were owned by municipalities and corporations, including predecessor companies to today's electric utilities. MGPs produced a variety of wastes and byproducts, including coal tar. Some of the waste and byproducts were sold for reuse or disposed off-site, and some were left at plant sites.

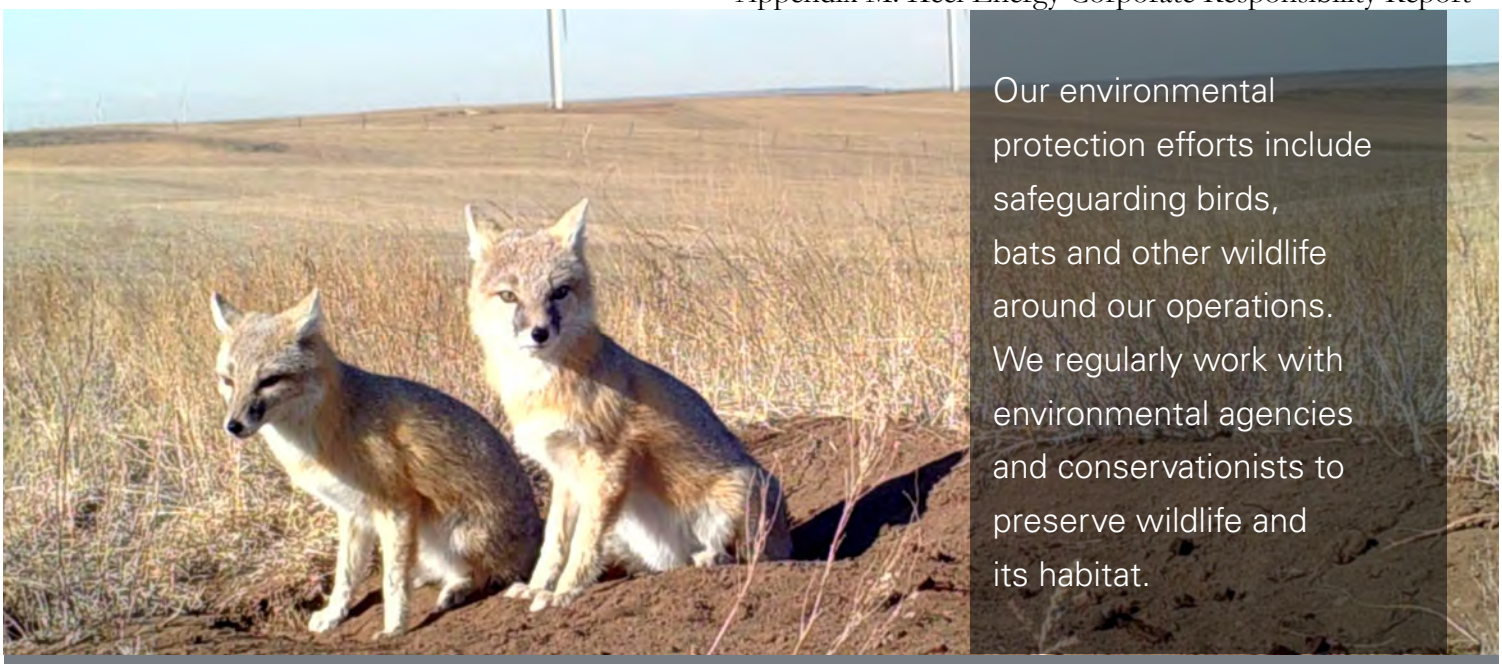
Given the extensive history of our operating companies — going back more than 100 years — Xcel Energy has inherited legacy MGP sites. All the plant facilities were closed and dismantled many years ago, and some of the properties where MGPs once operated have been sold. Over the years, Xcel Energy has worked cooperatively with environmental agencies and communities to successfully investigate and remediate former MGP sites when necessary.

Ashland

We successfully completed the remedial phase of an eight-year cleanup project along the lakefront of Lake Superior in Ashland, Wisconsin, which was one of the busiest industrial ports in the country during the late 1800s and early 1900s. A final site cap, as prescribed by the Record of Decision (ROD), will be installed at the site in 2019. It was the site not only of a legacy MGP, but other industrial operations. The MGP was operated at the site from 1885 to 1947 and provided gas for street lighting and businesses. Later, the site was used for a city-owned landfill and waste water treatment plant. We have owned a portion of the Ashland site since 1986.

The $200 million project was done under the supervision of EPA and the Wisconsin Department of Natural Resources. It involved more than 460,000 hours of work and employed best-in-class techniques, innovative technologies and a first-of-its-kind strategy to safely remove impacted lake sediments from the lakefront.

The effort included a unique agreement for cost recovery that effectively managed customer impact. In addition, numerous issues were successfully negotiated and litigated, including the recovery of more than $50 million in insurance and third-party settlements to reduce overall cost. Working closely with state and federal agencies, the project was environmentally sound and economically balanced. Throughout the effort, we maintained strong community relations with the city, customers, elected officials and local Native American tribes. With the project completed, the Ashland community can now move forward with waterfront-redevelopment plans.



Our environmental protection efforts include safeguarding birds, bats and other wildlife around our operations. We regularly work with environmental agencies and conservationists to preserve wildlife and its habitat.

Wildlife protection and biodiversity

Managing wildlife and habitat

We have a long history of working proactively with wildlife agencies and conservationists on special programs, research studies and regulatory efforts designed to protect wildlife and its habitat.

Our operations cover thousands of miles of transmission and power line right-of-ways, as well as the lakes, rivers and acres of land that surround our generating plants and wind farms. Given our footprint, we must take care and coexist responsibly with wildlife and the natural habitat that surrounds our facilities.

We consider our impact on wildlife as we upgrade, design and build facilities. For power line and plant construction projects, we evaluate our projects to determine possible impacts and take appropriate steps to help avoid and minimize potential risks. If we do have impacts, we have programs in place to document and report incidents to regulatory agencies, and then determine what actions we can take to prevent future issues.

2018 Results

- Under our Avian Protection Plans, 2,700 electric transmission and distribution power-line locations have been retrofitted with equipment to protect birds.
- We continued to support pollinator habitat on Xcel Energy property, especially in the Upper Midwest where we planted 47 acres of new habitat through three volunteer projects with agency and nonprofit partners. We even completed a demonstration garden at our downtown Amarillo headquarters by filling planters that surround the building with plants that are visually appealing and pollinator friendly.

- Our popular Bird Cam website had more than 1.3 million views with visitors tuning in to watch bald eagles, great horned owls and peregrine falcons. As early as 1989, we began working with the nonprofit Raptor Resource Project to install nest boxes at several of our Minnesota generating plants to help restore the peregrine falcon to the Mississippi River Valley. With the program's success, we began installing web-based cameras to share live video of the birds and their nesting habits. Our Bird Cam program grew from there.
- Through the Xcel Energy Foundation, we contributed nearly $436,000 in environmental stewardship grants to support organizations and programs that work to protect and enhance our natural environment.
- Former Vice President Walter Mondale, representatives from the National Park Service, and elected officials and community leaders from Minnesota and Wisconsin honored Xcel Energy for the company's donation of more than 24,000 acres of land along the St. Croix and Namekagon Rivers, which led to the creation of the Wild and Scenic Rivers Act of 1968. Events were held throughout Minnesota and Wisconsin in 2018 to recognize the 50th anniversary of the Act.

Avian Protection Plans

Xcel Energy was the first utility in the country to enter into a historic agreement with the U.S. Fish and Wildlife Service to proactively address potential issues involving birds and power-line structures, while helping the company comply with federal avian protection laws. Our utility operating companies entered into separate voluntary memorandums of understanding with USFWS in 2002 to collaborate on developing Avian Protection Plans.

Transmission and distribution lines and equipment can be attractive to birds for roosting and building nests and can pose a collision and electrocution hazard that may result in death or injury of the birds. In addition, threatened and endangered avian species and eagles are protected by the federal Endangered Species Act and the Bald and Golden Eagle Protection Act, respectively. Our Avian Protection Plans are a critical initiative for protecting birds and complying with these federal wildlife protection laws.

As part of its plan, each operating company developed a schedule for retrofitting facilities determined to pose a higher risk for bird injuries or deaths. Since then, we've had great success completing the retrofits in a timely manner, as called for under the plans. All of the initially identified retrofits have been completed in our Colorado, Texas and New Mexico service territories. In our Upper Midwest service territory, we have finished the highest priority lines and poles and are working through the next level of retrofit projects. Additionally, all of our facility design standards have been revised so that new or modified construction meets industry standards to prevent or mitigate avian incidents.

Xcel Energy employees are required under the plans to report injured or dead birds using the company's online reporting form. We then analyze whether reasonable retrofits or the installation of additional avian controls can minimize the risk of avian incidents at the location in the future. This reporting and evaluation process is another step in complying with federal avian protection laws and demonstrating our commitment to taking responsible actions for avian protection.

Helping Pollinators

Xcel Energy has been supporting the development and maintenance of pollinator habitats for over 30 years. With our Upper Midwest service territory coinciding with the Monarch Migration Corridor from Minnesota to Texas, we see tremendous potential to be a leader in helping pollinators.

The company currently has over 2,100 acres of pollinator habitat in Minnesota, North Dakota and Wisconsin. We have 44 active sites ranging from 0.25 to 800 acres on various company property including under transmission lines, around substations, power plants, community solar gardens, a wind project and company office sites. We are supporting and initiating projects that make a difference in the lives of pollinators, restoring native prairie ecosystems and targeting pollinator species of concern including the monarch butterfly, rusty patched bumblebee, and karner blue butterfly.

We can't achieve success on our own. We have many partners including state and federal agencies, communities and non-profit organizations. In 2018, we planted 40 acres of pollinator habitat around our Magic City Substation in Minot, North Dakota in collaboration with the U.S. Fish & Wildlife Service Partners for Wildlife. We partnered with Great River Greening and Xcel Energy employee volunteers to seed four acres of milk weed outside our Blue Lake Power Plant in Shakopee, Minnesota. An additional 16 acres will be planted in 2019 with the goal of creating a seed bank. We also partnered with the city of Burnsville, Minnesota in 2018 to plant three acres of pollinator habitat under transmission lines in an area where a new natural gas pipeline was installed leading to the Black Dog Generating Plant.

In Colorado, employee volunteer groups are partnering with nonprofit organizations to educate our employees on the importance of pollinator species and supporting projects for the development and maintenance of pollinator habitats in our communities. Partner organizations include the Butterfly Pavilion, Volunteers for Outdoor Colorado and the Colorado Pollinator Network.

Xcel Energy and the contractors we employ do not use chemicals that are harmful to beneficial insects in our vegetation management practices to control brush, trees and weeds on our rights-of-way and properties. This includes not using neonicotinoids, which is of special concern to people working to improve bee populations.

As we move forward with the pollinator initiative, we are focusing on developing habitat that can be sustained, allowing time for the sites to develop. Our primary goal is to continue to educate the communities we serve on the importance of the pollinators in their daily lives while utilizing company property to make a difference.

Responsible Wind Development

Wind energy is an important and growing part of our energy mix, especially as we look to build and operate more company-owned wind farms. Through wind, we are reducing carbon and other emissions and improving the environment in ways that ultimately support and protect wildlife. But, wind farms must be properly located, constructed, operated and monitored to minimize impacts to wildlife and protected species.

Project Siting and Development

Before construction, we carefully select wind farm sites to ensure impacts to birds, bats and other wildlife are minimized to the fullest extent practicable. This includes following the USFWS's Land-based Wind Energy Guidelines, conducting wildlife and habitat surveys and following other best practices. As part of this, we work with wind project developers, the USFWS and appropriate state wildlife and natural resource agencies during siting and permitting to ensure turbine locations are not in critical habitat for threatened and endangered species. If issues are identified, we work with the appropriate agencies to avoid or minimize impacts.

Our Sagamore Wind project in New Mexico is an example of our commitment to responsible wind development. The project developer sited turbines in locations that avoid and minimize impacts, and we are voluntarily entering into a conservation agreement. We have signed a letter of intent with the Lost Draw Conservation Bank to purchase preservation and restoration credits for the Lesser Prairie-Chicken (LPC) pending project approval and transfer of ownership.

Our participation in the Lost Draw Conservation Bank will help support LPC conservation by expanding, improving, and protecting high-quality LPC habitat. The bank is expected to restore thousands of acres of habitat by reconverting agricultural fields and removing tall woody species such as mesquite. It will eliminate existing fragmentation, such as pivot irrigation, wind mills, and other tall structures, and provide permanent protection of this high-quality habitat using easements held by a New Mexico land trust.

Construction

Pre-construction surveys are conducted prior to excavation for road or foundation construction, cable installation or crane relocation. This helps ensure that potential wildlife impacts can be minimized during wind farm construction. During construction of the Rush Creek wind project in Colorado, pre-construction surveys located burrowing owl nests in prairie dog colonies. Buffer zones were identified and marked to allow construction to continue while protecting the owls.

These surveys provide opportunities to identify other potential wildlife impacts due to indirect construction activity. At Rush Creek, for example, construction activity along a section of access road was restricted to protect an active swift fox den. We will also try to maintain existing trees and abandoned buildings on these sites when possible to avoid disturbing bat roosting habitat.

Wind Farm Operations

Once a wind farm is built, we continue to perform studies and monitor wind turbine operations. Our wind farms have detailed Bird and Bat Conservation Plans, which provide a framework for how we study, monitor and minimize impacts over the life a project — from wind farm planning to construction to the operation and maintenance and decommissioning.

Despite all these efforts, wildlife can be unpredictable, and there are no guarantees. We report injuries or fatalities to USFWS and appropriate state agencies. If protected avian species build nests in close proximity to existing wind turbines, we will evaluate what actions are needed to avoid and minimize impacts and engage our state and federal wildlife experts to ensure we take the right steps.

In addition to the wind farms we own, we also purchase a significant amount of wind capacity. We expect our third-party wind suppliers to perform similar permitting, reporting, reviews and studies of their wind farm operations.

Preserving Native American Cultural Resources

Protecting significant tribal cultural resources during the siting, construction and operation of our wind facilities is a priority. We voluntarily work with interested tribes to identify tribal cultural resources in areas where there are potentially important resources and may modify the final wind facility design to avoid impacts as much as possible. During construction, tribal cultural resource monitors may be used to help with the unexpected discovery of artifacts, ensuring they are evaluated and managed in a culturally appropriate manner.

During development and construction of the Foxtail wind project, we worked closely with the Standing Rock Sioux Tribe and others because the facility is sited near the Whitestone Hill State Historic Site in North Dakota, which was identified early in the development process as a historical site with major significance to a number of Tribes.

Enticing Ospreys to Alternative Nest Sites

Ospreys are federally protected raptors that have been successfully reintroduced in the Midwest, following decades of restoration and conservation efforts. Ospreys like distribution poles and transmission structures for nesting, but nests built on utility poles can pose a threat to the birds and may cause outages and damage to electrical equipment. Xcel Energy frequently erects alternative nest platforms that are taller than nearby lines in known osprey nesting areas to provide more attractive and safer nesting sites, while protecting system reliability. We also work closely with communities and civic groups to help them evaluate utility poles near high-quality osprey habitat, to identify alternative sites and assist with building and installing safe osprey nest platforms.

Lesser Prairie-Chicken Conservation Agreement

We voluntarily entered into a conservation agreement with the Western Association of Fish and Wildlife Agencies (WAFWA) pursuant to the Lesser Prairie-Chicken Range-Wide Conservation Plan to help protect this species of prairie grouse.

Rangelands in our Colorado, New Mexico and Texas service areas provide important habitat for the LPC. To participate in the conservation agreement, we pay enrollment and mitigation fees based on our anticipated development activity. We also take conservation measures, following avoidance, minimization and mitigation practices during operation, maintenance and new construction activities. As an example, we may bury distribution lines within the buffers of active breeding areas and use special types of pole construction in certain LPC habitat areas.

The goal of the WAFWA conservation plan is to increase the population of the species from about 17,000 birds in 2013 to 67,000 birds across Colorado, Kansas, New Mexico, Oklahoma and Texas. These efforts appear to be working — in 2018, WAFWA reported that there has been a steadily increasing LPC population trend over the last years.

July 1, 2019

—Via Electronic Filing—

Anne Sell
Minnesota Department of Commerce
85 Seventh Place East, Suite 280
St. Paul, MN 55101

RE: ANNUAL ELECTRIC UTILITY REPORT
DOCKET NO. E999/M-19-11

Dear Ms. Sell:

Northern States Power Company, doing business as Xcel Energy, submits the enclosed 2018 Electric Utility Annual Report required under Minn. Rule 7610.0130. Our Annual Report consists of the enclosed pages as well as individually uploaded live spreadsheets.

Private and Trade Secret Data Justification
This report contains private data on individuals such as the names, addresses, and usage of our largest electric customers. This information is maintained by the Company as private customer data, and for this reason, pursuant to Minn. Stat. §13.679, we have removed this data from the public version of our filing.

Please note that this report also contains Trade Secret information protected by the Minnesota Data Practices Act. That information has economic value, actual or potential, from not being generally known to, and not being readily ascertainable by proper means by other persons and is subject to efforts by the Company to protect the information from public disclosure. Xcel Energy maintains this information as a trade secret based on its economic value from not being generally known and not being readily ascertainable by proper means by other persons who can obtain economic value from its disclosure or use. For this reason, we ask that the data be treated as non-public data pursuant to Minn. Stat. § 13.37, subd. 1(b).

The forecast purchase and resale energy information has economic value to Xcel Energy, its customers, suppliers, and competitors. Because Xcel Energy competes for purchased energy, fuel and transportation services in a competitive marketplace, disclosure would directly harm Xcel Energy by making its delivered supply costs less competitive. For this reason, pursuant to Minn. Stat. § 13.37, subd. 2, we have removed this data from the public version of our filing.

We have electronically filed this document with the Minnesota Public Utilities Commission. Please feel free to contact me at (612) 330-6935 or gail.baranko@xcelenergy.com if you have any questions regarding this report.

Sincerely,

/s/

GAIL A. BARANKO
MANAGER, REGULATORY PROJECT MANAGEMENT

Enclosures

7610.0320 - Forecast Methodology

NSP Electric – Minnesota Annual Report
Peak Demand and Annual Electric Consumption Forecast

OVERALL METHODOLOGICAL FRAMEWORK

Xcel Energy prepared its forecast by major customer class and jurisdiction, using a variety of statistical and econometric techniques. The NSP System serves five jurisdictions. Minnesota, North Dakota and South Dakota are served by Northern States Power Company, a Minnesota corporation (NSP). Wisconsin and Michigan are served by Northern States Power Company, a Wisconsin corporation (NSPW). The overall methodological framework is "model oriented". The NSP and NSPW Systems operate as an integrated system. The forecast is referred to as the 2018v2.1 Forecast.

SPECIFIC ANALYTICAL TECHNIQUES

1. Econometric Analysis. Xcel Energy used econometric analysis to develop jurisdictional MWh sales forecasts at the customer meter for the following sectors (exceptions to this are noted in bullet 2):
    a. Residential without Space Heating;
    b. Residential with Space Heating;
    c. Small Commercial and Industrial;
    d. Large Commercial and Industrial (Minnesota only);
    e. Public Street and Highway Lighting (Minnesota only);
    f. Sales to Public Authorities (Minnesota only).

    Xcel Energy also used econometric analysis to develop the total system MW peak demand forecast.
2. Trend analysis was used for all other sectors, which includes North Dakota, South Dakota, Wisconsin and Michigan Large Commercial and Industrial; North Dakota, South Dakota, Wisconsin and Michigan Public Street and Highway Lighting; North, Dakota, South Dakota, Wisconsin and Michigan Other Sales to Public Authorities; and Interdepartmental sales (all jurisdictions).
3. Loss Factor Methodology. Loss factors by jurisdiction were used to convert the sales forecasts into system energy requirements (at the generator).
4. Judgment. Judgment is inherent to the development of any forecast. Whenever possible, Xcel Energy used quantitative models to structure its judgment in the forecasting process.

The sales forecasts are estimates of MWh levels measured at the customer meter. They do not include line or other losses. The various jurisdictional class forecasts are summed to yield the total system sales forecast. Native energy requirements are measured at the generator and include line and other losses. Xcel Energy creates native energy requirements based on the sales forecasts. A system loss factor for each jurisdiction, developed based on average historical losses, is applied to the sales forecast to calculate total losses. The sum of the MWh sales and the MWh losses equals the native energy requirements. The native energy requirements, along with peak producing weather and binary variables, then are used as independent variables within an econometric model to forecast MW peak demand for the

Xcel Energy North System.

MODELS USED

1. ***Residential Econometric Models.*** Sales to the residential sectors represent 29.7% of total NSP System electric sales in 2018. Residential sales are divided into with space heating and without space heating customer classes for Minnesota, North Dakota, and South Dakota. Econometric regression models using historical data are developed for each residential sector. A variety of independent variables are used in the models, including:
    - Number of customers;
    - Real Personal Income or Real Personal Income per Capita for respective jurisdiction;
    - Gross State Product;
    - Total Employment for respective jurisdiction;
    - Price of oil (WTI crude);
    - Actual heating and temperature humidity index (THI) degree days;
    - Number of monthly billing days;
    - Price of electricity ($/kWh).
2. ***Small Commercial and Industrial Econometric Models.*** The small commercial and industrial sector represents 43.7% of NSP System electric sales in 2018. The models are econometric regressions using historical data. The models include a combination of variables, including the following:
    - Number of small commercial and industrial customers;
    - Gross Metro Product for respective jurisdiction;
    - Gross State Product (North Dakota only);
    - Employment for respective jurisdiction;
    - Real Personal Income per Capita for respective jurisdiction;
    - Actual heating and temperature humidity index (THI) degree days;
    - Number of monthly billing days.
3. ***Large Commercial and Industrial Econometric Model.*** Sales to the large commercial and industrial sector represent 26.0% of NSP System electric sales in 2018. The regression model uses historical data and the following explanatory variables:
    - U.S. Industrial Production Index;
    - Number of monthly billing days.
4. ***Others.*** Sales to the "Others" sector represent 0.6% of NSP System electric sales in 2018. This sector includes Public Street and Highway Lighting (PSHL), Sales to Public Authorities (OSPA) and Interdepartmental (IDS) sales. Regression models are used to estimate sales for the PSHL and OSPA classes (Minnesota only), using historical data and a combination of variables, including the following:
    - Number of customers;
    - Population for Minneapolis St. Paul MSA;
    - Number of monthly billing days.
5. ***Municipals.*** As of 2014 there are no longer any municipal customers for whom NSP or NSPW provides firm service.

6. ***Peak Demand Model.*** An econometric model is developed to forecast base peak demand for the entire planning period. The model includes a combination of variables, including the following:
    - Weather normalized native energy requirements;
    - Peak producing weather by month.

METHODOLOGY STRENGTHS AND WEAKNESSES

The strength of the process Xcel Energy used for this forecast is the richness of the information obtained during the analysis. Xcel Energy's econometric forecasting models are based on sound economic and statistical theory. Historical modeling and forecast drivers are based on economic and demographic variables that are easily measured and analyzed. The use of models by class and jurisdiction gives greater insight into how the NSP System is growing, thereby providing better information for decisions to be made in the areas of generation, transmission, marketing, conservation, and load management.

With respect to accuracy, forecasts of this duration are inherently uncertain. Planners and decision makers must be keenly aware of the inherent risk that accompanies long-term forecasts. They must also develop plans that are robust over a wide range of future outcomes.

DATA FOR FORECASTS

Data Definitions

The following is a list of definitions of the variables used in Xcel Energy's econometric models.

Jurisdiction Abbreviations

M or MN	State of Minnesota
N or ND	State of North Dakota
S or SD	State of South Dakota
W or WI	State of Wisconsin
Mi or MI	State of Michigan

Monthly MWh Sales Series

SLS_Reswo(Juris)	Residential without space heating for given jurisdiction
SLS_ResSH(Juris)	Residential with space heating for given jurisdiction
SLS_SmCI(Juris)	Small commercial and industrial for given jurisdiction
SLS_LgCI(Juris)	Large commercial and industrial for given jurisdiction

Monthly Customer Series

Cust_Reswo(Juris)	Residential without space heating for given jurisdiction
Cust_ResSH(Juris)	Residential with space heating for given jurisdiction
Cust_SmCI(Juris)	Small commercial and industrial for given jurisdiction
Cust_LgCI(Juris)	Large commercial and industrial for given jurisdiction

Monthly Economic and Demographic Series

HH_(Juris)	Number of Households in given jurisdiction
NR_(Juris)	Total Population in given jurisdiction
CGMP_(MSA)	Real Gross Metro Product for given metropolitan statistical area
CGSP_(State)	Real Gross State Product for given state
EE_(Juris)	Total employment in given jurisdiction
EEMFG_(Juris)	Manufacturing employment in given jurisdiction
CYP_(Juris)	Real Personal Income in given jurisdiction
CYPNR_(Juris)	Real per capita Personal Income in given jurisdiction
(Juris)TotRes_RAP	Real Average Price for electric sales to residential customers

Monthly Data Variables used in Demand Model

THI12(Month)Cust	Temperature Humidity Index @12:00 noon multiplied by total retail customers
THI15(Month)Cust	Temperature Humidity Index @15:00 (3:00 PM) on the peak day multiplied by total retail customers
HDD(Season)	Normal Heating Degree Days on the day of the Peak multiplied by a binary variable for the season (winter – Wtr, shoulder month – sh)
WNActEnergy_LpYrAdj_12MoSum	12 month rolling sum of the weather normalized net energy requirements adjusted to remove the effect of leap years

Monthly Weather Variables

H65_bill (Juris) (Month)	HDD base 65 for given jurisdiction and month
T65_bill (Juris) (Month)	THI DD base 65 for given jurisdiction and month

Other Monthly Variables

BillDaysCellnet21	Billing Month Days

Monthly Binary Variables

Jan	Binary variable for the month of January
Feb	Binary variable for the month of February
Mar	Binary variable for the month of March
Apr	Binary variable for the month of April
May	Binary variable for the month of May
Jun	Binary variable for the month of June
Jul	Binary variable for the month of July
Aug	Binary variable for the month of August
Sep	Binary variable for the month of September
Oct	Binary variable for the month of October
Nov	Binary variable for the month of November
Dec	Binary variable for the month of December

Xcel Energy used internal and external data sources to create its MWh sales and MW peak demand forecast.

Historical MWh sales are taken from Xcel Energy's internal company records, fed by its billing system. Historical coincident net peak demand data is obtained through company records. The load management estimate is added to the net peak demand to derive the base peak demand.

Weather data (dry bulb temperature and dew points) were collected from the National Oceanic and Atmospheric Administration for the Minneapolis/St. Paul, Fargo, Sioux Falls, and Eau Claire areas. The heating degree-days and THI degree-days were calculated internally based on this weather data.

Economic and demographic data was obtained from the Bureau of Labor Statistics, U.S. Department of Commerce, and the Bureau of Economic Analysis. Typically they are accessed from IHS Global Insight, Inc. data banks, and reflect the most recent values of those series at the time of modeling.

DEMAND-SIDE MANAGEMENT PROGRAMS

The regression model results for the residential and commercial and industrial classes were reduced to account for the expected impacts of demand-side management (DSM) programs. The DSM methodology implemented for both the State of Minnesota and the State of South Dakota utilizes a transparent method for projecting the impacts of energy efficiency and load management on sales forecasts. There are three distinct steps to this process:

- Collect and calculate historical and current effects of DSM on observed sales
- Project the forecast using observed data with the impact of DSM removed (i.e. increase historical sales to show hypothetical case without DSM)
- Adjust the forecast to show the impact of all current and planned DSM in future years.

The Company's Saver's Switch program results in short-term interruptions of service designed to reduce system capacity requirements rather than permanent reductions in energy use, so it is not considered here.

Adjustments equivalent to those made to sales have also been made to the historical monthly energy and peak demand used in the peak demand regression model and to the resulting peak demand forecast.

BEHIND-THE-METER DISTRIBUTED SOLAR GENERATION

In response to the establishment of a Solar Energy Standard (SES) by the Minnesota Legislature an increased emphasis has been placed on distributed solar generation. A forecast of the expected impact on demand and energy has been developed based on new programs designed to meet goals established for the SES. The Minnesota class-level sales forecasts and the system peak demand forecast were adjusted to account for the impacts of customer sited behind-the-meter solar installations on the NSP System. This process of adjusting the sales and peak demand forecasts for behind-the-meter solar generation is similar to the adjustments made for DSM programs. There are three distinct steps to this process:

- Collect and calculate historical and current effects of behind-the-meter solar generation on observed sales and peak demand

- Project the forecast using observed data with the impact of behind-the-meter removed (i.e. increase historical sales to show hypothetical case without behind-the-meter solar generation)
- Adjust the forecast to show the impact of all current and planned behind-the-meter solar generation in future years.

PLUG-IN ELECTRIC VEHICLE CHARGING

The residential sales and peak demand forecasts also are adjusted to account for the increasing use of plug-in electric vehicle charging. The forecast adjustment for the monthly consumption of electricity for electric vehicle charging is based on a model that incorporates the stock of electric vehicles, electricity consumption per vehicle, an adoption rate for this technology, and financial incentives. The peak demand forecast adjustment is based on monthly electric vehicle energy consumption, daily consumption profile, and the time of day the monthly peak hour occurs.

DATA ADJUSTMENTS AND ASSUMPTIONS

1. Weather Adjustments. Xcel Energy adjusted its monthly weather data to reflect billing schedules. Therefore, the monthly weather data corresponds exactly with the billing month schedule.

2. Economic Adjustments. All price data and related economic series were deflated to 2009 constant dollars.

3. Large Customer Adjustments. The large commercial and industrial sales model results have been adjusted to account for announced changes in operations for large customers.

ASSUMPTIONS AND SPECIAL INFORMATION

Xcel Energy believes that its process is a reasonable and workable one to use as a guide for its future energy and load requirements. The underlying assumptions used to prepare Xcel Energy's median forecast are as follows:

1. Demographic Assumption. Population or household projections are essential in the development of the long-range forecast. The forecasts of customers are derived from population and household projections provided by IHS Global Insight, Inc., and reviewed by Xcel Energy staff. Xcel Energy customer growth mirrors demographic growth over the forecast period.

2. Weather Assumption. Xcel Energy assumed "normal" weather in the forecast horizon. Normal weather is defined as the average weather pattern over the 20-year period from 1998-2017. The variability of weather is an important source of uncertainty. Xcel Energy's energy forecasts are based on the assumption that the normal weather conditions will prevail in the forecast horizon. Weather-related demand uncertainties are not treated explicitly in this forecast.

3. Loss Factor Assumptions. The loss factors are important to convert the sales forecast to energy requirements. Xcel Energy uses a historical average loss factor for each jurisdiction, and assumes it will not change in the future.

FORECAST COORDINATION

Xcel Energy reports its energy and peak demand forecasts to the Midwest ISO (MISO). MISO then combines the forecasts of all its member utilities. Xcel Energy also reports its forecast to the Public Service Commission of Wisconsin as part of its Strategic Energy Assessment (SEA) process. In this process, the Wisconsin portion of the total Xcel Energy System load is combined with other Wisconsin electric utilities to form a statewide Wisconsin forecast.

7610.0410 – Future Facility Additions
7610.0420 – Future Facility Retirements

The Company's most recent, completed, Resource Plan (Docket No. E002/RP-15-21) was approved by Minnesota Public Utilities Commission (MPUC or the Commission) through an Order issued January 11, 2017. The next Resource Plan will be filed on July 1, 2019.

The Order to close the 2016-2030 Upper Midwest Resource Plan docket identified it reasonable to acquire 1000 MW of wind resources, manage solar acquisition to 650 MW between 2016-2021 through Community Solar Gardens and other acquisitions, retire Sherco units 1 & 2 in 2026 and 2023, respectively, identified a need for an additional 750 MW of intermediate capacity in 2026, and acquire an additional 400 MW of demand response by 2023.

The Company fulfilled the Ordered wind with the acquisition of resources through ownership and power purchase agreements. On September 22, 2016, the Company issued a Request For Proposals (RFP) for 1000 MW wind resources. The Company filed petitions (Docket No. E002/M-16-777, E002/M-17-694) to build, own, and operate an additional 1850 MW wind. These resources will achieve Commercial Operation between 4th quarter of 2019 and 4th quarter of 2021. Orders granting approval were received from the Minnesota Commission in September 2017 and May 2018, respectively.

Project	Fuel	Size	COD	Location	Type
Blazing Star 1	Wind	200 MW	2019	Lincoln County, MN	Self-Build
Blazing Star II	Wind	200 MW	2020	Lincoln County, MN	Self-Build
Foxtail	Wind	150 MW	2019	Dickey County, ND	Self-Build
Freeborn	Wind	200 MW	2020	Freeborn County, MN and Worth & Mitchell Counties, IA	Self-Build
Crowned Ridge	Wind	300 MW	2019	Codington County, SD	PPA
Crowned Ridge	Wind	300 MW	2019	Codington County, SD	BOT
Lake Benton	Wind	100 MW	2019	Pipestone County, MN	BOT
Clean Energy #1	Wind	100 MW	2019	Mercer & Morton Counties, ND	PPA
Dakota Range	Wind	300 MW	2021	Watertown, SD	Self-Build

Note: The Wind Petitions (Docket Nos. E002/M-16-777 and E002/M-17-694) provide additional information regarding these resources, including accredited capacity value, accredited capacities and production, and estimated costs.

The Company is on track to fulfill the Ordered solar acquisition through the Community Gardens (CSG) program. As of June 3, 2019, 559 MW of CSG

resources are connected. The program forecasts exceed 650 MW by 2019 year end.

The 2019 Review of Remaining Lives (Docket No. E,G002/D-19-161) – an annual review of the remaining lives depreciation of its electric and gas production and gas storage facilities service lives and salvage rates – updated the Remaining Life forecast for all Northern States Power Company – Minnesota (NSPM) units. This remaining life is associated with Financial End of Life for rate making purposes. Projections for the 2019-2029 timeframe are listed below. This is a tentative schedule, subject to change, pending the outcome of future Annual Review of Remaining Lives filings and the next Resource Plan filing.

Projected Plant Retirements*			
Year	**Unit/Site**	**Size (MW)****	**Fuel Type**
2019	Granite City	47	Natural Gas
2019	Bayfront 4	20	Natural Gas
2023	Blue Lake Units 1 thru 4	160	Oil
2024	Sherco Unit 2	765	Coal
2026	Wheaton	250	Oil/Natural Gas
2027	Sherco Unit 1	765	Coal
2027	Inver Hills	281	Natural Gas
2028	Red Wing	23	Refused Derived Fuel (RDF)
2028	Wilmarth	25	Refused Derived Fuel (RDF)

Notes:
* Years indicated represent the financial end-of-life as identified in the above referenced Remaining Lives docket. Financial end-of-life dates may be adjusted to coincide with the MISO Planning Year, ending May 31st.
** Size represents nameplate or contracted value of the resource.

The following list outlines current Power Purchase Agreements (PPA) and their scheduled termination dates.

Projected PPA Retirements			
Year	**Unit/Site**	**Size (MW)****	**Fuel Type**
2019	Koda/Rahr	12	Biomass
2019	Renewable PPAs	24	Renewable
2020	Manitoba Hydro	73	Hydro
2020	Renewable PPAs	1	Renewable
2021	Renewable PPAs	1	Renewable
2022	Renewable PPAs	7	Renewable
2023	Renewable PPAs	22	Renewable

2023	St. Paul CoGen	25	Biomass
2024	Renewable PPAs	13	Renewable
2025	Renewable PPAs	21	Renewable
2025	Manitoba Hydro	827	Hydro
2025	Invenergy	312	Natural Gas
2026	Mankato 1*	277	Natural Gas
2026	Renewable PPAs	10	Renewable
2027	Renewable PPAs	44	Renewable
2028	LS Power	235	Natural Gas
2028	Renewable PPAs	7	Renewable
2029	Renewable PPAs	17	Renewable

*Termination year may change pending a decision in MPUC Docket No. IP6949,E002/PA-18-702 regarding the proposed acquisition.

Xcel Energy proposes to fulfill future electric generating resource needs through our resource planning process and subsequent resource acquisition processes. The specific generation technology, location of future generation facilities, and mix of utility-owned, PPAs, and other resources are subject to approval by the Commission.

Energy discount is available to qualified low income customers under this schedule subject to the provisions contained in the Low Income Energy Discount Rider.

DEFINITION OF PEAK PERIODS
The on peak period is defined as those hours between 9:00 a.m. and 9:00 p.m. Monday through Friday, except the following holidays: New Year's Day, Good Friday, Memorial Day, Independence Day, Labor Day, Thanksgiving Day, and Christmas Day. When a designated holiday occurs on Saturday, the preceding Friday will be designated a holiday. When a designated holiday occurs on Sunday, the following Monday will be designated a holiday. The off peak period is defined as all other hours. Definition of on peak and off peak period is subject to change with change in Company's system operating characteristics.

OPTIONAL TRIAL SERVICE
Customers may elect time of day service for a trial period of three months. If a customer chooses to return to non-time of day service after the trial period, the customer will pay a charge of $20.00 for removal of time of day metering equipment.

TERMS AND CONDITIONS OF SERVICE

1. Customer selecting the above time of day rate schedule will remain on this rate for a period of not less than 12 months, except as provided under Optional Trial Service. While served under this schedule, the Residential Service rate is not available.

2. This schedule is also subject to provisions contained in Rules for Application of Residential Rates.

3. Time of Day Metering Charge per Month Option (Closed): For any customer who prior to November 1, 1988, elected to pay a non-refundable payment of $310.00 in lieu of the time of day metering charge, the monthly customer charge is reduced by $2.00.

MINNESOTA ELECTRIC RATE BOOK - MPUC NO. 2

RESIDENTIAL TIME OF USE PILOT PROGRAM Section No. 5
SERVICE 1st Revised Sheet No. 4.1
RATE CODE A72, A74

PILOT PROGRAM DESIGN
This is an experimental rate design for the residential Time of Use Pilot Program to be applied for two years from the effective date of this rate schedule. Participating customers will have received Residential Service without electric space heating prior to the Pilot, and may elect a return to the Residential Service rate schedule following the Pilot.

AVAILABILITY
A maximum of 10,000 customers will be selected to receive service with this rate schedule. The Company will determine pilot participants that receive service through the Hiawatha West, Midtown, or Westgate substations. Pilot participants will not include customers that are on net metering service or have other interconnected distributed generation on their premise, or customers that also receive Energy Controlled (Non-Demand Metered) Service, Residential Electric Vehicle Service, Limited Off-Peak Service, or customers that are medical equipment-dependent. Pilot participants may elect to opt out of participation in this Pilot for a specific premise.

DETERMINATION OF CUSTOMER BILLS
Customer bills shall reflect energy charges (if applicable) based on customer's kWh usage, plus a customer charge (if applicable), plus demand charges (if applicable) based on customer's kW billing demand as defined below. Bills may be subject to a minimum charge based on the monthly customer charge and / or certain monthly or annual demand charges. Bills also include applicable riders, adjustments, surcharges, voltage discounts, and energy credits. Bill Protection may also apply. Details regarding the specific charges applicable to this service and Bill Protection are listed below.

RATE

Customer Charge per Month		
Overhead (A72)	$8.00	
Underground (A74)	$10.00	
Energy Charge per kWh		
June – September		
On-Peak Period	$0.22576	R
Mid-Peak Period	$0.09013	R
Off-Peak Period	$0.02784	R
Other Months		
On-Peak Period	$0.19266	R
Mid-Peak Period	$0.07515	R
Off-Peak Period	$0.02784	R

In addition, customer bills under this rate are subject to the following adjustments and/or charges.

FUEL CLAUSE
Bills are subject to the adjustments provided for in the Fuel Clause Rider.

SERVICE (Continued) Original Sheet No. 4.2
RATE CODE A72, A74

RESOURCE ADJUSTMENT
Bills are subject to the adjustments provided for in the Conservation Improvement Program Adjustment Rider, the State Energy Policy Rate Rider, the Renewable Development Fund Rider, the Transmission Cost Recovery Rider, the Renewable Energy Standard Rider and the Mercury Cost Recovery Rider. N

ENVIRONMENTAL IMPROVEMENT RIDER
Bills are subject to the adjustments provided for in the Environmental Improvement Rider.

MONTHLY MINIMUM CHARGE
Customer Charge.

SURCHARGE
In certain communities, bills are subject to surcharges provided for in a Surcharge Rider.

LOW INCOME ENERGY DISCOUNT RIDER
Bills are subject to the adjustment provided for in the Low Income Energy Discount Rider.

REVENUE DECOUPLING MECHANISM RIDER
Bills are subject to the adjustments provided for in the Revenue Decoupling Mechanism Rider.

The following are terms and conditions for service under this tariff.

LATE PAYMENT CHARGE
Any unpaid balance over $10.00 is subject to a 1.5% late payment charge or $1.00, whichever is greater, after the date due. The charge may be assessed as provided for in the General Rules and Regulations, Section 3.5.

LOW INCOME ENERGY DISCOUNT
Energy discount is available to qualified low income customers under this schedule subject to the provisions contained in the Low Income Energy Discount Rider.

BILL PROTECTION
Billing charges considered for bill protection will include customer and energy charges, fuel cost charges and if applicable, the Residential Controlled Air Conditioning and Water Heating Rider discounts. Bill protection will be considered only for customers that have been pilot participants at the same residential location for 12 months from the effective date of this rate schedule, based on the first 12 months of participation in the pilot program. Any Pilot program billing charge in excess of 10 percent of the corresponding billing charge that would have been applied had the customer not been a pilot participant will be credited to the customer's account, including any applicable taxes. The bill protection in this paragraph will terminate after the first 12 months of participation in the pilot program.

Customers that have received LIHEAP assistance within the 12 months prior to participation in the pilot program will have bill protection determined monthly for the first 12 months of pilot participation for any billing charges in excess of the corresponding billing charge that would have been applied had the customer not been a pilot participant. This will be determined on a monthly basis for the first 12 months of pilot participation. For the second 12 months of pilot participation, the bill protection will continue to be provided for these LIHEAP assistance customers for billing charges in excess of 10 percent of the corresponding billing charge on an annual basis for the second 12 months of pilot participation. Customers that start to receive LIHEAP assistance after their participation in the pilot has begun will receive monthly bill protection up to the first 12 month anniversary of the pilot, and shall receive annual bill protection for the second 12 month period of the pilot. Customers who opt out or leave the pilot area will forego the annual protection otherwise offered for this second 12 month period. N

DEFINITION OF PEAK PERIODS
The On-Peak period is defined as those hours between 3:00 p.m. and 8:00 p.m. Monday through Friday, except the following holidays: New Year's Day, Good Friday, Memorial Day, Independence Day, Labor Day, Thanksgiving Day, and Christmas Day. When a designated holiday occurs on Saturday, the preceding Friday will be designated a holiday. When a designated holiday occurs on Sunday, the following Monday will be designated a holiday. The Mid-Peak period is defined as all hours not defined as On-Peak or Off-Peak periods. The Off-Peak period is defined as those hours between midnight (12:00 a.m.) and 6:00 a.m. every day. N

RESIDENTIAL CONTROLLED AIR CONDITIONING AND WATER HEATING RIDER
Customers that received service with the Residential Controlled Air Conditioning and Water Heating Rider in combination with Residential Service prior to participation in the pilot will have a revised discount for Company controlled central air conditioning or electric water heating that is specific to the pilot program. The controlled air conditioning discount is a monthly $10 credit applied during the billing months of June through September. The controlled electric water heating discount is a monthly $2 credit during each billing month. Pilot customers will receive these revised credits in place of percent discounts and are subject to all other terms of the Residential Controlled Air Conditioning and Water Heating Rider.

TERMS AND CONDITIONS OF SERVICE

The off-peak period is defined as all other hours. Definition of on-peak and off-peak period is subject to change with change in Company's system operating characteristics.

COMMUNICATION COSTS
The Company will maintain separate accounting of the information, education, advertising and promotion costs associated with electric vehicles as provided in Minn. Stat. §216B.1614, subd.2, paragraph (c) 2 by deferring the costs to a tracker account, and will petition the Minnesota Public Utilities Commission to recover the qualifying costs.

TERMS AND CONDITIONS OF SERVICE
1. Residential Electric Vehicle Service shall be separately served and metered and must at no time be connected to facilities serving customer's other loads. Metering may be installed as a sub-meter behind the customer’s main meter, in which case consumption under this rate schedule will be subtracted from the main meter for purposes of billing customer’s non-Electric Vehicle electricity usage.
2. The customer shall supply, at no expense to the Company, a suitable location for meters and associated equipment used for billing. Installations must conform to the Company’s specifications.
3. Company may require customer to provide access for Company-owned equipment for the recording and wireless communication of energy usage.
4. The rate contemplates that this service will utilize existing facilities with no additional major expenditures. Customer shall reimburse Company for any expenditure for facilities necessary to serve this load which would not otherwise be required to serve customer's load.
5. This schedule is also subject to provisions contained in Rules for Application of Residential Rates.
6. Customers that elect the Windsource program in calendar year 2015 for at least three (3) 100 kWh blocks or their entire usage on this schedule may receive a one-time $25 bill credit or gift card of the same value.

CANCELED

Northern States Power Company, a Minnesota corporation
Minneapolis, Minnesota 55401
MINNESOTA ELECTRIC RATE BOOK - MPUC NO. 2

ENERGY CONTROLLED SERVICE Section No. 5
(NON-DEMAND METERED) 30th Revised Sheet No. 9
RATE CODE A05

AVAILABILITY
Available to residential and commercial customers with permanently connected interruptible loads of up to 50 kW that would be under Company control. The types of loads served would include dual fuel space heating, water heating, and other loads subject to Company approval.

DETERMINATION OF CUSTOMER BILLS
Customer bills shall reflect energy charges (if applicable) based on customer's kWh usage, plus a customer charge (if applicable), plus demand charges (if applicable) based on customer's kW billing demand as defined below. Bills may be subject to a minimum charge based on the monthly customer charge and / or certain monthly or annual demand charges. Bills also include applicable riders, adjustments, surcharges, voltage discounts, and energy credits. Details regarding the specific charges applicable to this service are listed below.

RATE

	Residential	Commercial & Industrial	
Customer Charge	$4.95	$4.95	
Energy Charge per kWh	$0.04487	$0.04487	R
Optional			
June - September	$0.10301	$0.09256	R
Other Months	$0.04487	$0.04487	R

OPTIONAL ENERGY CHARGE
This option is available to customers with heat pump installations for non-interruptible service during June through September billing months.

In addition, customer bills under this rate are subject to the following adjustments and/or charges.

FUEL CLAUSE
Bills are subject to the adjustments provided for in the Fuel Clause Rider.

RESOURCE ADJUSTMENT
Bills are subject to the adjustments provided for in the Conservation Improvement Program Adjustment Rider, the State Energy Policy Rate Rider, the Renewable Development Fund Rider, the Transmission Cost Recovery Rider, the Renewable Energy Standard Rider and the Mercury Cost Recovery Rider.

ENVIRONMENTAL IMPROVEMENT RIDER
Bills are subject to the adjustments provided for in the Environmental Improvement Rider.

MONTHLY MINIMUM CHARGE
Customer Charge.

SURCHARGE
In certain communities, bills are subject to surcharges provided for in a Surcharge Rider.

REVENUE DECOUPLING MECHANISM RIDER
Bills are subject to the adjustments provided for in the Revenue Decoupling Mechanism Rider.

The following are terms and conditions for service under this tariff.

LATE PAYMENT CHARGE
Any unpaid balance over $10.00 is subject to a 1.5% late payment charge or $1.00, whichever is greater, after the date due. The charge may be assessed as provided for in the General Rules and Regulations, Section 3.5.

TERMS AND CONDITIONS OF SERVICE

1. The controllable load shall be permanently wired, separately served and metered, and at no time connected to facilities serving customer's firm load.

2. The duration and frequency of interruptions shall be at the discretion of Company. Interruption will normally occur at such times:
   a. When Company is required to use generation equipment or to purchase power that results in production costs in excess of $70 per MWh,
   b. When Company expects to establish an annual system peak demand, or
   c. At such times when, in Company's opinion, the reliability of the system is endangered.

3. Customer selecting Energy Controlled Service (Non-Demand Metered) must have a Company approved electric space heating system and must remain on this service for a minimum term of one year.

4. Customer selecting Energy Controlled Service (Non-Demand Metered) must be prepared for interruptions that will last longer than 12 hours per occurrence. Company shall not be liable for any loss or damage caused by or resulting from any interruption of service.

5. Electricity must be the primary source of energy for dual fuel space heating installations. Customer must have available alternative energy sources capable of supplying up to 30% of the annual heating needs during any heating season.

6. Customer's water heating system served under this rate must be designed and sized to be capable of providing customer's hot water needs for the full duration of the potential interruption periods.

For all customers, the minimum charge shall be the applicable customer charge.

SURCHARGE
In certain communities, bills are subject to surcharges provided for in a Surcharge Rider.

LATE PAYMENT CHARGE
Any unpaid balance over $10.00 is subject to a 1.5% late payment charge or $1.00, whichever is greater, after the date due. The charge may be assessed as provided for in the General Rules and Regulations, Section 3.5.

TERMS AND CONDITIONS OF SERVICE

1. Limited Off Peak Service shall be separately served and metered and must at no time be connected to facilities serving customer's other loads.

2. Company will not be liable for any loss or damage caused by or resulting from any interruption of service.

3. Customer selecting Limited Off Peak Service must remain on this service for a minimum term of one year, unless customer transfers to another interruptible service rate.

4. Customer has the option of directly controlling own load or allowing Company load control. If customer chooses Company load control, customer must:
   a. Provide a load-break switch or circuit breaker equipped with electronic trip and close circuits allowing for remote operation of customer's switch or circuit breaker by Company,
   b. Wire the trip and close circuits into a connection point designated by Company to allow installation of remote control equipment by Company, and
   c. Provide a continuous 120 volt AC power source at the connection point for operation of Company's remote control equipment.

5. A charge of $0.360 per kWh shall be applied to non-authorized energy used outside of the energized time period specified in this tariff. If this energy use occurs during three or more billing months, the Company reserves the right to remove customer from Limited Off Peak Service. R

6. The rate contemplates that this service will utilize existing facilities with no additional major expenditures. Customer shall reimburse Company for any expenditures for facilities necessary to serve this load which would not otherwise be required to serve customer's load.

RULES FOR APPLICATION OF RESIDENTIAL RATES

Section No. 5
7th Revised Sheet No. 13

1. The Residential Service, Residential Time of Day Service and Residential Time of Use Pilot Program are the only rates available to residential customers for domestic purposes in a single private residence. Energy Controlled Service (Non-Demand Metered), Limited Off Peak Service, Residential Electric Vehicle Service, Residential Electric Vehicle Pilot Service and Automatic Protective Lighting Service rate schedules are also available to qualifying residential customers. N

2. Normal service under the Residential Service, Residential Time of Day Service and Residential Time of Use Pilot Program rate schedules is single phase service rendered through one meter. Three phase service or service through more than one meter will be provided upon a one-time payment of an amount to reimburse Company for the additional investment. If customer is served through more than one meter, each meter will be separately billed. N N

3. Electric space heating charges are applicable only when customer's electric space heating equipment is used as customer's primary heating source.

4. Underground service charges will apply where the underground facilities are owned by Company, and Company has not been fully reimbursed for the added cost of such underground facilities.

5. Standby and Supplementary Service is available for any residential customer subject to the provisions in the General Rules and Regulations, Section 2.4. The Company's meter will be ratcheted to measure the flow of power and energy from Company to customer only.

6. A customer using electric service for domestic and non-domestic purposes jointly may combine such use through one meter on such rates as are available to general service customers.

7. The Residential Service and Residential Time of Day Service rate schedules are available to farm installations which were served on the separate Farm Service rate schedule prior to its cancellation on November 1, 1988. Residential Service and Residential Time of Day Service to these qualifying farm customers is limited to 120/240 volts single phase service rendered through one meter. Motors and other equipment which interfere with service to neighboring customers and all transformer type welding machines larger than 25 kilovolt-amperes are not permitted as part of this service.

MINNESOTA ELECTRIC RATE BOOK - MPUC NO. 2

AUTOMATIC PROTECTIVE LIGHTING SERVICE Section No. 5
RATE CODE A07 21st Revised Sheet No. 14

AVAILABILITY
Available to all types of customers except for municipal street lighting purposes.

DETERMINATION OF CUSTOMER BILLS
Customer bills shall reflect energy charges (if applicable) based on customer's kWh usage, plus a customer charge (if applicable), plus demand charges (if applicable) based on customer's kW billing demand as defined below. Bills may be subject to a minimum charge based on the monthly customer charge and / or certain monthly or annual demand charges. Bills also include applicable riders, adjustments, surcharges, voltage discounts, and energy credits. Details regarding the specific charges applicable to this service are listed below.

RATE

Designation of Lamp	Monthly Rate Per Unit	
Area Units		
100W High Pressure Sodium	$7.57	R
175W Mercury (1)	$7.57	R
250W High Pressure Sodium	$12.07	R
400W Mercury (1)	$12.07	R
Directional Units		
250W High Pressure Sodium	$14.37	R
400W High Pressure Sodium	$17.98	R
1,000W Mercury (1)	$27.82	R

(1) Available to existing installations only.

D

In addition, customer bills under this rate are subject to the following adjustments and/or charges.

SERVICE INCLUDED IN RATE
Company shall own, operate, and maintain the lighting unit including the fixture, lamp, ballast, photoelectric control, mounting brackets, and all necessary wiring. Company shall furnish all electric energy required for operation of the unit.

FUEL CLAUSE
Bills are subject to the adjustments provided for in the Fuel Clause Rider.

AUTOMATIC PROTECTIVE LIGHTING SERVICE (Continued) Section No. 5
RATE CODE A07 11th Revised Sheet No. 15

RESOURCE ADJUSTMENT
Bills are subject to the adjustments provided for in the Conservation Improvement Program Adjustment Rider, the State Energy Policy Rate Rider, the Renewable Development Fund Rider, the Transmission Cost Recovery Rider, the Renewable Energy Standard Rider and the Mercury Cost Recovery Rider.

ENVIRONMENTAL IMPROVEMENT RIDER
Bills are subject to the adjustments provided for in the Environmental Improvement Rider.

SURCHARGE
In certain communities, bills are subject to surcharges provided for in a Surcharge Rider.

The following are terms and conditions for service under this tariff.

LATE PAYMENT CHARGE
Any unpaid balance over $10.00 is subject to a 1.5% late payment charge or $1.00, whichever is greater, after the date due. The charge may be assessed as provided for in the General Rules and Regulations, Section 3.5.

TERM OF AGREEMENT
Agreement shall be for a term of three years. If not then terminated by at least 30 days' written notice by either party, the agreement shall continue until so terminated.

TERMS AND CONDITIONS OF SERVICE
1. Service available subject to the provisions for Automatic Protective Lighting Service of the General Rules and Regulations, Section 5.4.

2. The lamp shall be lighted and extinguished by a photoelectric control furnished by the Company. The hours of burning shall be from approximately one-half hour after sunset until one-half hour before sunrise, every night.

3. If illumination of a lamp is interrupted and said illumination is not resumed within 72 hours from the time Company receives notice thereof from customer, one-thirtieth of the monthly compensation for such unit shall be deducted for each night of non-illumination after such notice is received.

4. Company reserves the right to discontinue service if equipment is abused.

5. Company will convert mercury vapor lighting units to high pressure sodium upon failure of the mercury vapor ballast.

MONTHLY MINIMUM CHARGE
Customer Charge, or Customer Charge plus Demand Charge if served at Direct Current.

SURCHARGE
In certain communities, bills are subject to surcharges provided for in a Surcharge Rider.

LOW INCOME ENERGY DISCOUNT RIDER
Bills are subject to the adjustment provided for in the Low Income Energy Discount Rider.

REVENUE DECOUPLING MECHANISM RIDER
Bills in rate codes A09, A10, and A11 are subject to the adjustments provided for in the Revenue Decoupling Mechanism Rider.

The following are terms and conditions for service under this tariff.

LATE PAYMENT CHARGE
Any unpaid balance over $10.00 is subject to a 1.5% late payment charge or $1.00, whichever is greater, after the date due. The charge may be assessed as provided for in the General Rules and Regulations, Section 3.5.

TERMS AND CONDITIONS OF SERVICE FOR ALTERNATING CURRENT CUSTOMERS
Company shall install a demand meter for a customer when:
1. Customer's connected load is estimated to be 20 kW or greater,
2. Customer is served single phase and has a service entrance capacity greater than 200 amperes,
3. Customer is served three phase at 120/208 or 120/240 volts and has a service entrance capacity greater than 200 amperes,
4. Customer is served three phase at 240/480 or 277/480 volts and has a service entrance capacity greater than 100 amperes, or
5. Customer's average monthly kWh use for four consecutive months exceeds 3,500 kWh.

If a demand meter is installed in accordance with the above, the customer may remain on the Small General Service schedule as long as customer's maximum demand is less than 25 kW. When the customer achieves an actual maximum demand of 25 kW or greater, the customer will be placed on the General Service schedule in the next billing month. A customer with a billing demand of less than 25 kW for 12 consecutive months will be given the option of returning to the Small General Service schedule.

DETERMINATION OF CONNECTED LOAD FOR DIRECT CURRENT SERVICE
The nameplate rating shall be the basis of determining the connected load and shall be assumed to be one kW for each hp of nameplate rating. In any case, where there is reasonable doubt as to correctness of manufacturer's rating or where insufficient or no rating exists, the Company may fix the rating by test. For billing purposes, the demand shall be rounded to the nearest 0.1 kW.

The following are terms and conditions for service under this tariff.

LATE PAYMENT CHARGE
Any unpaid balance over $10.00 is subject to a 1.5% late payment charge or $1.00, whichever is greater, after the date due. The charge may be assessed as provided for in the General Rules and Regulations, Section 3.5.

DEFINITION OF PEAK PERIODS
The on peak period is defined as those hours between 9:00 a.m. and 9:00 p.m. Monday through Friday, except the following holidays: New Year's Day, Good Friday, Memorial Day, Independence Day, Labor Day, Thanksgiving Day, and Christmas Day. When a designated holiday occurs on Saturday, the preceding Friday will be designated a holiday. When a designated holiday occurs on Sunday, the following Monday will be designated a holiday. The off peak period is defined as all other hours. Definition of on peak and off peak period is subject to change with change in Company's system operating characteristics.

OPTIONAL TRIAL SERVICE
Customers may elect time of day service for a trial period of three months. If a customer chooses to return to non-time of day service after the trial period, the customer will pay a charge of $25.00 for removal of time of day metering equipment.

TERMS AND CONDITIONS OF SERVICE
1. Customer selecting the above time of day rate schedule will remain on this rate for a period of not less than 12 months. While served under this schedule, the Small General Service rate is unavailable.

2. Company shall install a demand meter for a customer when:
   a. Customer's connected load is estimated to be 20 kW or greater,
   b. Customer is served single phase and has a service entrance capacity greater than 200 amperes,
   c. Customer is served three phase at 120/208 or 120/240 volts and has a service entrance capacity greater than 200 amperes,
   d. Customer is served three phase at 240/480 or 277/480 volts and has a service entrance capacity greater than 100 amperes, or
   e. Customer's average monthly kWh use for four consecutive months exceeds 3,500 kWh.

   If a demand meter is installed in accordance with the above, the customer may remain on the Small General Time of Day Service schedule as long as customer's maximum demand is less than 25 kW. When the customer achieves an actual maximum demand of 25 kW or greater, the customer will be placed on the General Time of Day Service schedule in the next billing month. A customer with a billing

RATE CODE A12, A16, A18, A22 12th Revised Sheet No. 24.1

TERMS AND CONDITIONS OF SERVICE (Continued)

demand of less than 25 kW for 12 consecutive months will be given the option of returning to the Small General Time of Day Service schedule.

3. Optional Metering Service: Optional metering is available subject to the provisions in the General Rules and Regulations, Section 1.5, for the following applications:

   a. Kilowatt-hour Metered Service: For applications where a non-time of day meter is used, the time of day metering charge will be waived and the applicable lower monthly Customer Charge shall apply.

   b. Unmetered Service: For applications where no metering is installed, the applicable lower monthly Customer Charge shall apply. If requested by Company, the customer agrees to receive one or more combined bills for all their unmetered service locations. For purposes of applying the appropriate customer service charge, one customer service charge shall be applied for every point of delivery. A point of delivery shall be any location where a meter would otherwise be required under this schedule.

   c. Low Wattage Unmetered Service: For applications where customer owns and operates multiple electronic devices in at least 500 locations within Company's Minnesota electric service area. Such electronic devices are: 1) individually located at each point of delivery, 2) rated at less than 400 Watts, and 3) operated with a continuous and constant load level year round. Each individual electronic device must not in any way interfere with Company operations and service to adjacent customers. This optional metering service is not applicable to electric service for traffic signals, civil defense, or lighting. Company reserves the right to evaluate customer requests for this optional metering service to determine eligibility.

      The monthly fixed charge under this optional metering service shall be $0.30 per device for devices with a rating of 100 Watts or less. For devices with a rating over 100 Watts but less than 400 Watts, the monthly fixed charge shall be $1.20 per device. R

      In place of metered usage for each device, customer will be billed for the predetermined energy usage in kWh per device. The energy charge shall equal the sum of the predetermined energy usage for customer's low wattage devices in service for the billing month multiplied by the Constant Hourly Energy Charge applicable for the billing month.

      Customer shall contract for this optional metering service through an electric service agreement with Company.

GENERAL SERVICE Section No. 5
RATE CODE A14 31st Revised Sheet No. 26

AVAILABILITY
Available to any non-residential customer for general service where customer is not required to be on a time-of-day rate schedule. Once the customer's 15-minute measured demands are equal to or greater than 1,000 kW for at least 4 of the past 12 consecutive months, the customer will be transferred to the General Time of Day service.

DETERMINATION OF CUSTOMER BILLS
Customer bills shall reflect energy charges (if applicable) based on customer's kWh usage, plus a customer charge (if applicable), plus demand charges (if applicable) based on customer's kW billing demand as defined below. Bills may be subject to a minimum charge based on the monthly customer charge and / or certain monthly or annual demand charges. Bills also include applicable riders, adjustments, surcharges, voltage discounts, and energy credits. Details regarding the specific charges applicable to this service are listed below.

RATE

Customer Charge per Month	$25.64		
Service at Secondary Voltage	Oct-May	Jun-Sep	R
Demand Charge per Month per kW	$10.49	$14.79	
Energy Charge per kWh	$0.03407		R
Energy Charge Credit per Month per kWh			
All kWh in Excess of 400 Hours Times the Billing Demand	$0.01518		R

	January - December		
Voltage Discounts per Month	Per kW	Per kWh	
Primary Voltage	$0.80	$0.00105	R
Transmission Transformed Voltage	$1.55	$0.00267	R
Transmission Voltage	$2.35	$0.00277	R

Once the customer's 15-minute measured demands are equal to or greater than 1,000 kW for at least 4 of the past 12 consecutive months, the customer will be transferred to the General Time of Day service.

DETERMINATION OF CUSTOMER BILLS
Customer bills shall reflect energy charges (if applicable) based on customer's kWh usage, plus a customer charge (if applicable), plus demand charges (if applicable) based on customer's kW billing demand as defined below. Bills may be subject to a minimum charge based on the monthly customer charge and / or certain monthly or annual demand charges. Bills also include applicable riders, adjustments, surcharges, voltage discounts, and energy credits. Details regarding the specific charges applicable to this service are listed below.

RATE

Customer Charge per Month		$25.64	
Service at Secondary Voltage	Oct-May	Jun-Sep	R
Demand Charge per Month per kW	$11.00	$15.54	
Energy Charge per kWh		$0.03577	R
Energy Charge Credit per Month per kWh			
All kWh in Excess of 400 Hours Times the Billing Demand		$0.01593	R

Voltage Discounts per Month	January - December Per kW	Per kWh	
Primary Voltage	$0.80	$0.00108	R
Transmission Transformed Voltage	$1.55	$0.00274	R
Transmission Voltage	$2.35	$0.00285	R

In addition, customer bills under this rate are subject to the following adjustments and/or charges.

FUEL CLAUSE
Bills are subject to the adjustments provided for in the Fuel Clause Rider.

RESOURCE ADJUSTMENT
Bills are subject to the adjustments provided for in the Conservation Improvement Program Adjustment Rider, the State Energy Policy Rate Rider, the Renewable Development Fund Rider, the Transmission Cost Recovery Rider, the Renewable Energy Standard Rider and the Mercury Cost Recovery Rider.

GENERAL SERVICE (Continued) Section No. 5
RATE CODE A14 8th Revised Sheet No. 27

ENVIRONMENTAL IMPROVEMENT RIDER
Bills are subject to the adjustments provided for in the Environmental Improvement Rider.

SURCHARGE
In certain communities, bills are subject to surcharges provided for in a Surcharge Rider.

LOW INCOME ENERGY DISCOUNT RIDER
Bills are subject to the adjustment provided for in the Low Income Energy Discount Rider.

The following are terms and conditions for service under this tariff.

LATE PAYMENT CHARGE
Any unpaid balance over $10.00 is subject to a 1.5% late payment charge or $1.00, whichever is greater, after the date due. The charge may be assessed as provided for in the General Rules and Regulations, Section 3.5.

DETERMINATION OF DEMAND
The adjusted demand in kW for billing purposes shall be determined by dividing the maximum actual demand in kW by the power factor expressed in percent but not more than a 90% power factor and multiplying the quotient so obtained by 90% and rounding to the nearest whole kW. In no month shall the demand to be billed be considered as less than current month's adjusted demand in kW or 50% of the greatest monthly adjusted demand in kW during the preceding 11 months. In no month shall the billing demand be greater than the value in kW determined by dividing the kWh sales for the billing month by 100 hours per month.

The greatest monthly adjusted demand in kW during the preceding 11 months shall not include the additional demand which may result from customer's use of standby capacity contracted for under the Standby Service Rider.

MAXIMUM DEMAND
The maximum actual demand in kW shall be the greatest 15 minute load during the month for which bill is rendered.

POWER FACTOR
For three phase customers with services above 200 amperes or above 480 volts, the power factor for the month shall be determined by permanently installed metering equipment. For all single phase customers and three phase customers with services 200 amperes or less, a power factor of 90% will be assumed.

Northern States Power Company, a Minnesota corporation
Minneapolis, Minnesota 55401
MINNESOTA ELECTRIC RATE BOOK – MPUC NO. 2

GENERAL SERVICE (Continued) Section No. 5
RATE CODE A14 7th Revised Sheet No. 28

OFF SEASON LOAD SERVICE
The optional Off Season Load Service is available under this schedule subject to the provisions contained in the Off Season Load Rider.

STANDBY SERVICE
Standby Service and Supplemental Generation Service are available under this schedule subject to the provisions contained in the Standby Service Rider or Supplemental Generation Service Rider.

COMPETITIVE SERVICE
Competitive Service is available under this schedule subject to the provisions contained in the Competitive Response Rider.

MINIMUM DEMAND TO BE BILLED
The monthly minimum billing demand shall not be less than provided above.

SPLIT SERVICE
When approved by Company, customer's service may be split between General Service and General Time of Day Service rates. Only Company approved storage space cooling and storage space heating equipment qualifies for the General Time of Day Service portion of a split service installation. The thermal storage equipment shall be permanently wired, separately served and metered, and at no time connected to the general service portion of the split service installation. Each portion of customer's split service installation will be considered separately for all other rate application purposes.

GENERAL SERVICE (Continued) Section No. 5
RATE CODE A14 5th Revised Sheet No. 28.1

TERMS AND CONDITIONS OF SERVICE

1. Alternating current service is provided at the following nominal voltage:
   a. Secondary Voltage: Single or three phase from 208 volts up to but not including 2,400 volts,
   b. Primary Voltage: Three phase from 2,400 volts up to but not including 69,000 volts,
   c. Transmission Transformed Voltage: Three phase from 2,400 volts up to but not including 69,000 volts, where service is provided at the Company's disconnecting means of a distribution substation transformer, or
   d. Transmission Voltage: Three phase at 69,000 volts or higher.

   Service voltage available in any given case is dependent upon voltage and capacity of Company lines in vicinity of customer's premises.

2. Transmission Transformed Service is available only to customers served by an exclusively dedicated distribution feeder. Customer will be responsible for the cost of all facilities necessary to interconnect at the Company's disconnecting means of a distribution substation transformer.

3. Transmission Service is available at transmission voltage, subject to the terms and conditions contained in the Company's General Rules and Regulations, Section 5.1(B).

4. Customer selecting General Service will remain on this rate for a period of not less than 12 months.

5. If a customer has a billing demand of less than 25 kW for 12 consecutive months, the customer will be given the option of returning to the Small General Service schedule.

In addition, customer bills under this rate are subject to the following adjustments and/or charges.

FUEL CLAUSE
Bills are subject to the adjustments provided for in the Fuel Clause Rider.

RESOURCE ADJUSTMENT
Bills are subject to the adjustments provided for in the Conservation Improvement Program Adjustment Rider, the State Energy Policy Rate Rider, the Renewable Development Fund Rider, the Transmission Cost Recovery Rider, the Renewable Energy Standard Rider and the Mercury Cost Recovery Rider.

ENVIRONMENTAL IMPROVEMENT RIDER
Bills are subject to the adjustments provided for in the Environmental Improvement Rider.

SURCHARGE
In certain communities, bills are subject to surcharges provided for in a Surcharge Rider.

LOW INCOME ENERGY DISCOUNT RIDER
Bills are subject to the adjustment provided for in the Low Income Energy Discount Rider.

The following are terms and conditions for service under this tariff.

LATE PAYMENT CHARGE
Any unpaid balance over $10.00 is subject to a 1.5% late payment charge or $1.00, whichever is greater, after the date due. The charge may be assessed as provided for in the General Rules and Regulations, Section 3.5.

DEFINITION OF PEAK PERIODS
The on peak period is defined as those hours between 9:00 a.m. and 9:00 p.m. Monday through Friday, except the following holidays: New Year's Day, Good Friday, Memorial Day, Independence Day, Labor Day, Thanksgiving Day, and Christmas Day. When a designated holiday occurs on Saturday, the preceding Friday will be designated a holiday. When a designated holiday occurs on Sunday, the following Monday will be designated a holiday. The off peak period is defined as all other hours. Definition of on peak and off peak period is subject to change with change in Company's system operating characteristics.

(Continued on Sheet No. 5-31)

Northern States Power Company, a Minnesota corporation
Minneapolis, Minnesota 55401
MINNESOTA ELECTRIC RATE BOOK - MPUC NO. 2

GENERAL TIME OF DAY SERVICE (Continued) Section No. 5
RATE CODE A15, A17, A19 8th Revised Sheet No. 31

DETERMINATION OF ON PEAK PERIOD DEMAND
The actual on peak period demand in kW shall be the greatest 15-minute load for the on peak period during the month for which the bill is rendered. The adjusted demand in kW for billing purposes shall be determined by dividing the actual on peak demand by the power factor expressed in percent but not more than 90%, multiplying the quotient so obtained by 90%, and rounding to the nearest whole kW. In no month shall the on peak period demand to be billed be considered as less than the current month's adjusted on peak period demand in kW, or 50% of the greatest monthly adjusted on peak period demand in kW during the preceding 11 months. In no month shall the on peak billing demand be greater than the value in kW determined by dividing the kWh sales for the billing month by 100 hours per month.

The greatest monthly adjusted on peak period demand in kW during the preceding 11 months shall not include the additional demand which may result from customer's use of standby capacity contracted for under the Standby Service Rider.

DETERMINATION OF OFF PEAK PERIOD DEMAND IN EXCESS OF ON PEAK PERIOD DEMAND
The actual off peak period demand in kilowatts shall be the greatest 15-minute load for the off peak period during the month for which the bill is rendered rounded to the nearest whole kW. In no month shall the off peak period demand for billing purposes be considered as less than the current month's actual off peak period demand in kW, or 50% of the greatest monthly actual off peak period demand in kW during the preceding 11 months.

The greatest monthly adjusted off peak period demand in kW during the preceding 11 months shall not include the additional demand which may result from customer's use of standby capacity contracted for under the Standby Service Rider.

The off peak period demand in excess of on peak period demand in kW to be billed shall be determined by subtracting the billing on peak period demand from the actual off peak period demand as defined above only the off peak period demand is greater.

POWER FACTOR
For three phase customers with services above 200 amperes, or above 480 volts, the power factor for the month shall be determined by permanently installed metering equipment. For all single phase customers and three phase customers with services 200 amperes or less, a power factor of 90% will be assumed.

GENERAL TIME OF DAY SERVICE (Continued) Section No. 5
RATE CODE A15, A17, A19 6th Revised Sheet No. 32

COMPETITIVE SERVICE
Competitive Service is available under this schedule subject to the provisions contained in the Competitive Response Rider.

STANDBY SERVICE
Standby Service is available under this schedule subject to the provisions contained in the Standby Service Rider.

MINIMUM DEMAND TO BE BILLED
The monthly minimum on peak period billing demand shall not be less than provided above.

SPLIT SERVICE
When approved by Company, customer's service may be split between General Service and General Time of Day Service rates. Only Company approved storage space cooling and storage space heating equipment qualifies for the General Time of Day Service portion of a split service installation. The thermal storage equipment shall be permanently wired, separately served and metered, and at no time connected to the general service portion of the split service installation. Each portion of customer's split service installation will be considered separately for all other rate application purposes.

OPTIONAL TRIAL SERVICE
Customers may elect time of day service for a trial period of three months. If a customer chooses to return to non-time of day service after the trial period, the customer will pay a charge of $35.00 for removal of time of day metering equipment.

TERMS AND CONDITIONS OF SERVICE
1. Alternating current service is provided at the following nominal voltages:
   a. Secondary Voltage: Single or three phase from 208 volts up to but not including 2,400 volts,
   b. Primary Voltage: Three phase from 2,400 volts up to but not including 69,000 volts,
   c. Transmission Transformed Voltage: Three phase from 2,400 volts up to but not including 69,000 volts, where service is provided at the Company's disconnecting means of a distribution substation transformer, or
   d. Transmission Voltage: Three phase at 69,000 volts or higher.

   Service voltage available in any given case is dependent upon voltage and capacity of Company lines in vicinity of customer's premises.

MINNESOTA ELECTRIC RATE BOOK - MPUC NO. 2

GENERAL TIME OF DAY SERVICE (Continued) Section No. 5
RATE CODE A15, A17, A19 5th Revised Sheet No. 32.1

TERMS AND CONDITIONS OF SERVICE (Continued)

2. Transmission Transformed Service is available only to customers served by an exclusively dedicated distribution feeder. Customer will be responsible for the cost of all facilities necessary to interconnect at the Company's disconnecting means of a distribution substation transformer.

3. Transmission Service is available at transmission voltage, subject to the terms and conditions contained in the Company's General Rules and Regulations, Section 5.1(B).

4. Customer selecting the above time of day rate schedule will remain on this rate for a period of not less than 12 months.

5. If a customer has a billing demand of less than 25 kW for 12 consecutive months, the customer will be given the option of returning to the Small General Time of Day Service schedule.

6. Optional Metering Service: Optional metering is available subject to the provisions in the General Rules and Regulations, Section 1.5, for the following applications:
   a. Kilowatt-hour Metered Service: For applications where a non-time of day meter is used, the time of day metering charge will be waived and the applicable lower monthly Customer Charge shall apply.
   b. Unmetered Service: This rate is for applications where no metering is installed and the applicable lower monthly Customer Charge shall apply. If requested by Company, the customer agrees to receive one or more combined bills for all their unmetered service locations. For purposes of applying the appropriate customer service charge, one customer service charge shall be applied for every point of delivery. A point of delivery shall be any location where a meter would otherwise be required under this schedule.

AVAILABILITY
Available to any non-residential customer for general service who agrees to control demand to a predetermined level whenever required by Company and where customer is not required to be on a time-of-day rate schedule. Once the customer's total 15-minute measured demands (Firm plus Controllable) are equal to or greater than 1000 kW for at least 4 of the past 12 consecutive months, the customer will be transferred to the Peak Controlled Time of Day service. Availability is restricted to customers with a minimum Controllable demand of 50 kW.

DETERMINATION OF CUSTOMER BILLS
Customer bills shall reflect energy charges (if applicable) based on customer's kWh usage, plus a customer charge (if applicable), plus demand charges (if applicable) based on customer's kW billing demand as defined below. Bills may be subject to a minimum charge based on the monthly customer charge and / or certain monthly or annual demand charges. Bills also include applicable riders, adjustments, surcharges, voltage discounts, and energy credits. Details regarding the specific charges applicable to this service are listed below.

MINNESOTA ELECTRIC RATE BOOK - MPUC NO. 2

PEAK CONTROLLED SERVICE Section No. 5
RATE CODE A23 21st Revised Sheet No. 40

AVAILABILITY
Available to any non-residential customer for general service who agrees to control demand to a predetermined level whenever required by Company and where customer is not required to be on a time-of-day rate schedule. Once the customer's total 15-minute measured demands (Firm plus Controllable) are equal to or greater than 1000 kW for at least 4 of the past 12 consecutive months, the customer will be transferred to the Peak Controlled Time of Day service. Availability is restricted to customers with a minimum Controllable demand of 50 kW.

DETERMINATION OF CUSTOMER BILLS
Customer bills shall reflect energy charges (if applicable) based on customer's kWh usage, plus a customer charge (if applicable), plus demand charges (if applicable) based on customer's kW billing demand as defined below. Bills may be subject to a minimum charge based on the monthly customer charge and / or certain monthly or annual demand charges. Bills also include applicable riders, adjustments, surcharges, voltage discounts, and energy credits. Details regarding the specific charges applicable to this service are listed below.

RATE

Customer Charge per Month		$55.00	
Service at Secondary Voltage			
Energy Charge per kWh		$0.03577	R
Energy Charge Credit per Month per kWh			
All kWh in Excess of 400 Hours		$0.01593	R
Times the Sum of All Billing Demands			
Demand Charge per Month per kW	Tier 1	Tier 2

RATE CODE A23 18th Revised Sheet No. 41

D

In addition, customer bills under this rate are subject to the following adjustments and/or charges.

FUEL CLAUSE
Bills are subject to the adjustments provided for in the Fuel Clause Rider.

RESOURCE ADJUSTMENT
Bills are subject to the adjustments provided for in the Conservation Improvement Program Adjustment Rider, the State Energy Policy Rate Rider, the Renewable Development Fund Rider, the Transmission Cost Recovery Rider, the Renewable Energy Standard Rider and the Mercury Cost Recovery Rider.

ENVIRONMENTAL IMPROVEMENT RIDER
Bills are subject to the adjustments provided for in the Environmental Improvement Rider.

SURCHARGE
In certain communities, bills are subject to surcharges provided for in a Surcharge Rider.

LOW INCOME ENERGY DISCOUNT RIDER
Bills are subject to the adjustment provided for in the Low Income Energy Discount Rider.

LATE PAYMENT CHARGE
Any unpaid balance over $10.00 is subject to a 1.5% late payment charge or $1.00, whichever is greater, after the date due. The charge may be assessed as provided for in the General Rules and Regulations, Section 3.5.

DEFINITION OF PERFORMANCE FACTOR (PF)
Performance factor is defined in percentage terms as the average of the July and August calendar month unadjusted maximum Controllable Demand occurring from 1:00 p.m. to 7:00 p.m. on weekdays, or which has been permanently shifted out of normal control period times, divided by the unadjusted maximum annual Controllable Demand. Customers claiming permanent load shifts must provide verification to Company, based on NSP's established criteria.

DETERMINATION OF DEMAND
Maximum Actual Demand in kW shall be the greatest 15-minute load during the billing month.

Adjusted Demand in kW for billing purposes shall be determined by dividing the Maximum Actual Demand in kW by the power factor expressed in percent but not more than a 90% power factor and multiplying the quotient so obtained by 90% and rounding to the nearest whole kW.

(Continued on Sheet No. 5-42)

Northern States Power Company, a Minnesota corporation
Minneapolis, Minnesota 55401
MINNESOTA ELECTRIC RATE BOOK - MPUC NO. 2

PEAK CONTROLLED SERVICE (Continued) Section No. 5
RATE CODE A23 6th Revised Sheet No. 42

DETERMINATION OF DEMAND (Continued)
Predetermined Demand shall be specified and agreed to by the customer and Company. Customer's Adjusted Demand must not exceed the Predetermined Demand Level (PDL) during a control period.

Standard PDL customers must agree to a fixed demand level and limit load to that level during a control period.

Optional PDL customers must agree to reduce demand by a fixed amount during a control period. Customer's Firm Demand will vary from month-to-month while the Controllable Demand remains fixed each month. The Firm Demand will be the Adjusted Demand (based on the Maximum Actual Demand for the month) less the fixed amount of Controllable Demand. Customer's PDL will be the monthly adjusted demand less the fixed load reduction. Customers selecting the Optional PDL must either be equipped with back-up generation to provide the fixed load reduction or have a specific load that can be separately sub-metered and has an annual load factor of 90% or greater.

Firm Demand for the billing month shall be the lesser of Predetermined Demand or Adjusted Demand, except in months when customer fails to control load to Predetermined Demand Level when requested by Company. In these months, Firm Demand shall be the adjusted demand established during the control period. For optional PDL customers, Firm Demand shall be Adjusted Demand less Controllable Demand, except in months when customer fails to control the full amount of their fixed Controllable Demand. In these months the Firm Demand shall be the Adjusted Demand less the amount of Demand that was controlled as shown by meter measurement.

Controllable Demand shall be the difference between Adjusted Demand during the billing month and the greater of Predetermined Demand or Firm Demand, but never less than zero.

Minimum Demand to be billed each month as either Firm Demand, Controllable Demand or a combination of both shall not be less than the current month's adjusted demand in kW.

POWER FACTOR
The power factor for the month shall be determined by permanently installed metering equipment.

ANNUAL MINIMUM DEMAND CHARGE
The Annual Minimum Demand Charge shall be no less than six times the average monthly Firm Demand Charge per kW times the maximum Predetermined Demand, plus six times the Controllable Demand Charge per kW times the maximum Controllable Demand.

RATE CODE A23 6th Revised Sheet No. 43

TIER 1 PEAK CONTROLLED SHORT NOTICE
Tier 1 Peak Controlled Short Notice is available under this schedule subject to the provisions contained in the Tier 1 Peak Controlled Short Notice Rider.

COMPETITIVE SERVICE
Competitive Service is available under this schedule subject to the provisions contained in the Competitive Response Rider.

OTHER PROVISIONS
Peak Controlled Service is also subject to provisions contained in Rules for Application of Peak Controlled Services.

TERMS AND CONDITIONS OF SERVICE
1. Alternating current service is provided at the following nominal voltages:
   a. Secondary Voltage: Single or three phase from 208 volts up to but not including 2,400 volts,
   b. Primary Voltage: Three phase from 2,400 volts up to but not including 69,000 volts,
   c. Transmission Transformed Voltage: Three phase from 2,400 volts up to but not including 69,000 volts, where service is provided at the Company's disconnecting means of a distribution substation transformer, or
   d. Transmission Voltage: Three phase at 69,000 volts or higher.

   Service voltage available in any given case is dependent upon voltage and capacity of Company lines in vicinity of customer's premises.

2. Transmission Transformed Service is available only to customers served by an exclusively dedicated distribution feeder. Customer will be responsible for the cost of all facilities necessary to interconnect at the Company's disconnecting means of a distribution substation transformer.

3. Transmission Service is available at transmission voltage, subject to the terms and conditions contained in the Company's General Rules and Regulations, Section 5.1(B).

AVAILABILITY
Available to any non-residential customer for general service who agrees to control demand to a predetermined level whenever required by Company. Availability is restricted to customers with a minimum controllable demand of 50 kW.

AVAILABILITY-MANDATORY
Effective November 1, 2007, this rate schedule is mandatory for any Peak Controlled customer having a 15-minute measured demand equal to or greater than 1000 kW for at least 4 of the past 12 consecutive months. Customer will remain on this rate schedule on a mandatory basis unless their demand remains below 1000 kW for 12 consecutive months.

AVAILABILITY-OPTIONAL
This rate schedule is optional for any non-residential customer for general service where customer is not required to be on a time-of-day rate.

DETERMINATION OF CUSTOMER BILLS
Customer bills shall reflect energy charges (if applicable) based on customer's kWh usage, plus a customer charge (if applicable), plus demand charges (if applicable) based on customer's kW billing demand as defined below. Bills may be subject to a minimum charge based on the monthly customer charge and / or certain monthly or annual demand charges. Bills also include applicable riders, adjustments, surcharges, voltage discounts, and energy credits. Details regarding the specific charges applicable to this service are listed below.

PEAK CONTROLLED TIME OF DAY SERVICE Section No. 5
(Continued) 12th Revised Sheet No. 46
RATE CODE A24

LOW INCOME ENERGY DISCOUNT RIDER
Bills are subject to the adjustment provided for in the Low Income Energy Discount Rider.

The following are terms and conditions for service under this tariff.

LATE PAYMENT CHARGE
Any unpaid balance over $10.00 is subject to a 1.5% late payment charge or $1.00, whichever is greater, after the date due. The charge may be assessed as provided for in the General Rules and Regulations, Section 3.5.

DEFINITION OF PEAK PERIODS
The on peak period is defined as those hours between 9:00 a.m. and 9:00 p.m. Monday through Friday, except the following holidays: New Year's Day, Good Friday, Memorial Day, Independence Day, Labor Day, Thanksgiving Day, and Christmas Day. When a designated holiday occurs on Saturday, the preceding Friday will be designated a holiday. When a designated holiday occurs on Sunday, the following Monday will be designated a holiday. The off peak period is defined as all other hours. Definition of on peak and off peak period is subject to change with change in Company's system operating characteristics.

DEFINITION OF PERFORMANCE FACTOR (PF)
Performance factor is defined in percentage terms as the average of the July and August calendar month unadjusted maximum Controllable Demand occurring from 1 p.m. to 7 p.m. on weekdays, or which has been permanently shifted out of normal control period times, divided by the unadjusted maximum annual Controllable Demand. Customers claiming permanent load shifts must provide verification to Company, based on NSP established criteria.

DETERMINATION OF DEMAND
Maximum Actual On Peak Period Demand in kW shall be the greatest 15-minute load for the on peak period during the billing month.

Adjusted On Peak Period Demand in kW for billing purposes shall be determined by dividing the Maximum Actual on peak demand by the power factor expressed in percent but not more than 90%, multiplying the quotient so obtained by 90%, and rounding to the nearest whole kW.

Maximum Actual Off Peak Period Demand in kW shall be the greatest 15-minute load for the off peak period during the billing month rounded to the nearest whole kW. In no month shall the off peak period demand for billing purposes be considered as less than the current month's actual off peak period demand in kW.

Off Peak Period Demand in Excess of On Peak Period Demand in kW to be billed shall be determined by subtracting the billing on peak period demand from the actual off peak period demand only if the off peak period demand is greater.

(Continued on Sheet No. 5-47)

Northern States Power Company, a Minnesota corporation
Minneapolis, Minnesota 55401
MINNESOTA ELECTRIC RATE BOOK - MPUC NO. 2

PEAK CONTROLLED TIME OF DAY SERVICE Section No. 5
(Continued) 7th Revised Sheet No. 47
RATE CODE A24

Predetermined Demand shall be specified and agreed to by the customer and Company. Customer's adjusted on peak demand must not exceed the predetermined demand level (PDL) during a control period.

Standard PDL customers must agree to a fixed demand level and limit load to that level during a control period.

Optional PDL customers must agree to reduce demand by a fixed amount during a control period. Customer's Firm Demand will vary from month-to-month while the Controllable Demand remains fixed each month. The Firm Demand will be the Adjusted Demand (based on the Maximum Actual Demand for the month) less the fixed amount of Controllable Demand. Customer's PDL will be the monthly adjusted on peak demand less the fixed load reduction. Customers selecting the Optional PDL must either be equipped with back-up generation to provide the fixed load reduction or have a specific load than can be separately sub-metered and has an annual load factor of 90% or greater.

Firm Demand for the billing month shall be the lesser of Predetermined Demand or Adjusted on Peak Period Demand, except in months when customer fails to control load to Predetermined Demand Level when requested by Company. In these months, Firm Demand shall be the adjusted on peak period demand established during the control period. For Optional PDL customers, Firm Demand shall be Adjusted On Peak Demand less Controllable Demand, except in months when customer fails to control the full amount of their fixed Controllable Demand, In the months the Firm Demand shall be the Adjusted On Peak Period Demand less the amount of Demand that was controlled as shown by meter measurement.

Controllable Demand shall be the difference between Adjusted on Peak Period Demand during the billing month and the greater of Predetermined Demand or firm demand, but never less than zero.

Minimum On Peak Demand to be billed each month as either Firm Demand Controllable Demand or combination of both shall not be less than the current month's Adjusted on Peak Period Demand in kW.

POWER FACTOR
The power factor for the month shall be determined by permanently installed metering equipment.

ANNUAL MINIMUM DEMAND CHARGE
The Annual Minimum Demand Charge shall be no less than six times the average monthly Firm Demand Charge per kW times the predetermined demand, plus six times the Controllable Demand Charge per kW times the maximum Controllable Demand.

TIER 1 ENERGY CONTROLLED SERVICE
Tier 1 Energy Controlled Service is available under this schedule subject to the provisions contained in the Tier 1 Energy Controlled Service Rider.

TIER 1 PEAK CONTROLLED SHORT NOTICE
Tier 1 Peak Controlled Short Notice option is available under this schedule subject to the provisions contained in the Tier 1 Peak Controlled Short Notice Rider.

COMPETITIVE SERVICE
Competitive Service is available under this schedule subject to the provisions contained in the Competitive Response Rider.

OTHER PROVISIONS
Peak Controlled Time of Day Service is also subject to provisions contained in Rules for Application of Peak Controlled Services.

TERMS AND CONDITIONS OF SERVICE
1. Alternating current service is provided at the following nominal voltages:
   a. Secondary Voltage: Single or three phase from 208 volts up to but not including 2,400 volts,
   b. Primary Voltage: Three phase from 2,400 volts up to but not including 69,000 volts,
   c. Transmission Transformed Voltage: Three phase from 2,400 volts up to but not including 69,000 volts, where service is provided at the Company's disconnecting means of a distribution substation transformer, or
   d. Transmission Voltage: Three phase at 69,000 volts or higher.

   Service voltage available in any given case is dependent upon voltage and capacity of Company lines in vicinity of customer's premises.

2. Transmission Transformed Service is available only to customers served by an exclusively dedicated distribution feeder. Customer will be responsible for the cost of all facilities necessary to interconnect at the Company's disconnecting means of a distribution substation transformer.

3. Transmission Service is available at transmission voltage, subject to the terms and conditions contained in the Company's General Rules and Regulations, Section 5.1(B).

Northern States Power Company, a Minnesota corporation
Minneapolis, Minnesota 55401
MINNESOTA ELECTRIC RATE BOOK - MPUC NO. 2

RULES FOR APPLICATION OF PEAK CONTROLLED SERVICES

Section No. 5
7th Revised Sheet No. 48

1. Customer has the responsibility of controlling own load to Predetermined Demand Level.

2. Customer must allow Company to inspect and approve the load control installation and equipment provided by customer.

3. If controlled demand is 10,000 kW or larger, Company may require customer to:
   a. Provide auxiliary contacts for remote indication of position of switch or circuit breaker used to control demand and wire auxiliary contacts into a connection point designated by Company,
   b. Install the remote breaker indication equipment provided by Company, and
   c. Provide a continuous 120 volt AC power source at the connection point for operation of the Company remote breaker indication equipment.

4. Company will endeavor to give customer one hour notice of commencement of control period, and as much additional notice as is practical. However, control period may be commenced without notice should Company determine such action is necessary.

5. Failure to Control Charge: An additional charge of $8.00 ($10.00 for Tier 1) per kW will apply during each Company specified control period to the amount by which customer's Maximum Adjusted Demand or Maximum Adjusted On Peak Period Demand exceeds their predetermined demand level. After three such customer failures to control load to their Predetermined Demand Level, Company reserves the right to increase the Predetermined Demand Level, or transfer customer to General Service or General Time of Day Service and apply the cancellation charge specified in customer's Electric Service Agreement.

6. The duration and frequency of control periods shall be at the discretion of Company. Control periods will normally occur when:
   a. Company expects a reasonable possibility of system load levels surpassing the level for which NSP has sufficient accredited capacity under the Midwest Reliability Organization (MRO) or any successor organization, including reserve requirements, or
   b. In Company's opinion, the reliability of the system is endangered.

RULES FOR APPLICATION OF PEAK CONTROLLED SERVICES (Continued)

Section No. 5
6th Revised Sheet No. 49

7. Customer must execute an Electric Service Agreement with Company which will include:

   Peak Controlled Service - Tier 1
   a. A minimum initial 10 year term of service which includes a one year trial period and a three year cancellation notice effective after the initial term of service,
   b. The Predetermined Demand Level, or the fixed Controllable Demand if Optional PDL is selected which may be revised subject to approval by Company,
   c. Maximum 150 hours of interruption,
   d. Cancellation charge terms, and
   e. Control period notice.

   Peak Controlled Service - Tier 2
   a. A minimum initial five year term of service which includes a one year trial period and a six month cancellation notice effective after the initial term of service,
   b. The Predetermined Demand Level, or the fixed Controllable Demand if Optional PDL is selected which may be revised subject to approval by Company,
   c. Maximum 80 hours of interruption,
   d. Cancellation charge terms, and
   e. Control period notice.

8. Peak Controlled Service customers choosing the Tier 1 rate option will be subject to an additional monthly charge for a Company approved and installed two-way communications system. The system equipment allows NSP to determine remotely customer load levels and to notify customers of control periods.

9. Minimum Controllable Demand during the Company's peak season shall be 50 kW.

10. Company shall not be liable for any loss or damage caused by or resulting from any interruption of service.

11. Company will determine, at a service location designated by Company, the number of services supplied. Customers requesting special facilities will be charged the additional costs incurred for such facilities.

RULES FOR APPLICATION OF PEAK CONTROLLED SERVICES (Continued)

Section No. 5
6th Revised Sheet No. 50

12. Customers choosing the Predetermined Demand Level option requiring a fixed demand reduction will be subject to an additional charge for metering and billing when additional metering equipment is necessary. The additional charge is $17.00 per month for an application using a single meter in close proximity to customer's service point. The additional charge for more complex applications will be based on the actual costs of the specific application.

13. Company will maintain Firm Demand Charge rates at the General Service and General Time of Day Service levels, whichever is applicable.

14. Any customer with generating equipment which is operated in parallel with Company must comply with all requirements associated with parallel operations as specified in the General Rules and Regulations of the Company.

15. Any load served by customer generation during Company requested control periods must be served by Company at all other times.

16. Customers selecting Peak Controlled Services will normally remain at a specific Performance Factor level for a minimum of one year, subject to the Company's discretion. The Company may transfer customers between Performance Factor levels following verification of a customer's performance, as defined in the applicable rate schedule and as specified in the customer's Electric Service Agreement. This rate contemplates that increases in summer Controllable Demand, which thereby affect a customer's Performance Factor level, will be at sufficient consumption levels to yield a July and August calendar month load factor of 34% or greater. The Company reserves the right to limit the customer's eligibility to be on a higher Performance Factor level due to the above restriction.
